

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

### Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

- + *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
- + *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
- + *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
- + *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

### About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at <http://books.google.com/>

### MONOMANIA.

*A Clinical Lecture, delivered at the Philadelphia Hospital.*

By H. C. Wood, M.D., LL.D.\*

[Reported by WILLIAM H. MORRISON, M.D.]

GENTLEMEN,—The subject of to-day's lecture is monomania. This term literally means one mania. It was originally proposed by the great alienist Esquirol, who

\* Physician to the Hospital, and Professor of Diseases of the Nervous System in the University of Pennsylvania.

employed it to signify a condition of exaltation in which the patient was in a perpetual and chronic state of high spirits, with excessive mental and emotional activity. If the term monomania were used with this meaning we should include under it cases which really belonged to chronic mania in its mildest type. We should also find that those cases which might be included under monomania would sometimes pass from this condition of excitement to one of depression. The term has been used by different alienists with almost every conceivable meaning. In these lectures I shall use it to cover a very large class of chronic insanities in which the insane condition is limited, at least in its marked manifestations, to certain portions of the

brain-functions. The term *monomania*, thus limited, covers those cases which are commonly termed cases of partial insanity, in which one function of the mind is either almost solely or most markedly affected. The best scientific definition of monomania that I know of is that given by Spitzka. He says, "Monomania is a chronic form of insanity, based on an acquired or transmitted neurodegenerative taint, and manifesting itself in anomalies of the conceptional sphere,—*i.e.*, the sphere of thought,—which, while it does not destroy entirely the mental mechanism, dominates it." This definition is, I think, scarcely wide enough. I believe that the term monomania should include not only those cases in which the intellectual or conceptional sphere is involved, but also those in which the emotional condition is affected. There are, as you know, certain passions, such as avarice, envy, vanity, and so on, which are really as much cerebral functions as is the reasoning power itself. There are cases in which these emotions become so magnified in their power that they dominate the whole individual. As an example may be taken the miser, in whom that portion of the brain whose functional activity is connected with avarice has become so excessively active that it subjugates entirely the ego. An old gentleman who resided in this State in early life had thoroughly well educated and taken care of his family. His wife died, and he then became more and more queer and more and more poverty-stricken, so that he scarcely provided his daughters with the necessities of life. He was taken care of by an old colored woman, whom he had bought for very little. His children were clad in the coarsest clothing, and, as I have said, scarcely received sufficient food. The old man eventually died, and fifteen thousand dollars in gold was found under his pillow. Every day he had crawled out of bed early in the morning and hid this bag of gold in a certain part of the room, and after the bed had been made would crawl back and put it under the pillow. Securities were also found amounting to hundreds of thousands of dollars. Avarice had become so overweening that it was beyond the power of the patient to control it. It is perfectly parallel to the appetite which is engendered for strong drink. The man first drinks through the will; but there frequently does develop a condition of the nervous system in which the power of the brain is so lowered and influenced by the long-continued habit that the man is a monomaniac as regards drink. The

thirst for alcohol absolutely dominates him, and is entirely beyond his power to control. It is, of course, a very difficult matter,—and it may be in individual cases impossible,—for us to draw the line between sanity and insanity,—*i.e.*, between the condition in which the patient could, if he would, control the appetite, and that in which the power of self-control is really lost; but assuredly the difficulty of drawing the line ought not to cause us to reject these cases of emotional disorder as belonging with the insanities. Did we not at our last lecture on melancholia learn that a general depression of spirits may be for a time the sole evidence of an insanity? And if what may be considered a generalized emotional disturbance marks general insanity, surely a particularized emotional disturbance, such as exists in the miser, may mark particularized insanity,—*i.e.*, monomania.

The difficulty of decision exists in all forms of monomania. Let me cite you a case from my experience.

Several years ago I was called to a palatial mansion, and I was met in a boudoir by a handsome young wife, quiet, perfectly lady-like, and self-restrained in her manner. She said to me, "Doctor, I have sent for you under very painful circumstances, because I feel that I must confide in some one." She then went on to say that she had syphilis, and that this had been given to her by her husband, and that she had had a child born in a certain watering-place, and that it had died from hereditary syphilis. She further told me in detail of having personally detected her husband's infidelities. I examined the woman thoroughly, but could not find the slightest evidence of specific disease. I finally wrote to the physician who had attended the woman at the birth of the child. He at once replied that the child was well formed and perfect, and that it had died from an ordinary acute infantile disease. I then assured the woman that she had not had syphilis. She expressed herself as much relieved, but was unrelenting towards her husband, who she said kept a mistress, and frequently annoyed her by communicating with said mistress at places of amusement where they were together, and by having said mistress to drive immediately behind them in the park. She had detectives employed to watch her husband, and had a well-known lawyer engaged to superintend the detectives. After this had gone on for some weeks, I began to suspect that there was something wrong with the woman's brain, and to watch her.

To make a long story short, my patient watched her husband more and more closely, spent hundreds of dollars, and at last one night at a theatre pointed out as the paramour of her husband a lady who was well known and entirely beyond suspicion. The whole of her story was undoubtedly invented, although she herself believed it. Her husband, however, believed that she was full of the devil and wanted to torment him. She was all the time acting against her own interest. She could have obtained anything from her husband if she had acted in a decent manner towards him. There was nothing to be done in the case. The couple were sent to Europe, but the same condition remained, and they finally separated. This was undoubtedly a case of well-formed monomania, in which the woman's intellectual powers, except in this regard, were perfect. She mingled in society, reasoned well, and did everything well, but she had this delusion, by which her whole life was altered. I found in that case, as is found in most cases of monomania, that clear back to childhood there had been evidences of something not quite right with the cerebral functions. The woman had always been extremely vain, wildly ambitious to shine in fashionable society, and with a marked excess of egotism. These are characteristics which frequently precede the evidences of monomania. This was well exemplified in the history of Guiteau.

Although Esquirol used the term monomania as belonging to those cases in which there was an excess of animal spirits and of the emotions, such as ambition and anger, which are related to aggressiveness and power, there can be no doubt that there are two distinct classes of monomaniacal persons,—those in which there is a condition of emotional exaltation, and those in which there is a condition of emotional depression. In other words, precisely as in general insanity we have two types of cases, represented by mania and by melancholia, so do we have in this monomania, or partial or limited insanity, two classes of cases, the one corresponding to general insanity with emotional exaltation, and the second corresponding to general insanity with emotional depression.

I have already expressed the opinion that monomania may exist without the presence of a delusion and be purely emotional. At the same time, in most cases, sooner or later there comes a distinct delusion. Some writers say that the character of the delusion is dominated by the character of the emotional disturbance. Others say that the character of

the emotional excitement is the result of that of the delusion. For instance, a man who imagines that he is the Czar of all the Russias is, by the very belief itself, kept in a perpetual state of exaltation, while a man who believes that he has committed the unpardonable sin is by his belief thrown into a state of deep depression. I do not believe that the delusion produces the mental state always, or that the mental state produces or dominates the character of the delusion. It seems to me that all that can be said is that these two things are correlated, and that a condition of mental depression tends to delusions of persecution and delusions of a depressive type, and that in a condition of emotional exaltation the delusions partake of this general character.

The delusions of monomania, like the delusions of ordinary general insanity, often grow out of something having a real existence. A melancholic or hypochondriacal monomaniac may have some bad feeling, which is increased in his mind until it dominates his whole life: thus a dyspeptic symptom leads him to the belief that he has no stomach. These cases are to be distinguished from the cases of hypochondriacal melancholia by the fact that the delusion is "systematized." The systematized delusion, you will remember, is one said to be characteristic of monomania, and is one about which the patient reasons, and which he defends.

As an example of this let me cite a case which recently came to my notice,—that of a gentleman, now dead, who was at the time a colonel in the United States Army. This case also well illustrates how closely monomania relates itself to sanity, and how difficult it sometimes is to draw the line, and to convince others, especially those who have no medical training, where the line is to be drawn. This man was, at the time I speak of, stationed at one of the frontier posts of the country, and was performing, with satisfaction to all, the duties appertaining to his rank. One day he said to a friend, "My life in this frontier post, from its monotony, would be absolutely unsupportable if it were not for my daily mail which I get from my dead friends. I had a letter from your brother last week, and every morning I live in expectation of receiving a letter from some deceased friend or relative." He was asked how the letters came, and it was learned that they were received through a certain living medium in the eastern part of the United States. This lady would almost daily write a letter to this man, which was

received by him with absolute credence as coming through her from the spirit world. We come right here upon the delusions of spiritualism, and we come to a class of cases in which it is very difficult to say where sanity ends and insanity begins. In matters of religious belief, every man who believes strongly in a certain faith might consider every other person who believes in a different faith to be insane. Profound belief in the daily presence of spirits may coexist with great scientific or business acumen.

Although it seems impossible to fix a line which shall separate a sane from an insane religious trust or belief, it can hardly be doubted that many of the devotees of spiritualism ought to be considered as monomaniacs. Let me refer again to the colonel I spoke of a moment ago. On one occasion he said, "There is one thing that gives me great comfort, and that is that I am a descendant from the Virgin Mary." Some one intimating a doubt of that genealogy, he continued, "I know that I am a descendant of the Virgin Mary, because I had a letter from her, and she says so, and she certainly ought to know." Can we hesitate in deciding that here was a delusion which was thoroughly systematized and logically defended by its holder? The first premise, that he received letters from the spirits, was false, but his reasoning based upon it was sound.

Another case which came under my notice a year or two ago was very interesting, and also illustrates the difficulty sometimes met with in drawing the line. It was that of a lady who saw visions. If a person sees a vision, and recognizes that it is a vision and does not believe that it has a real existence, that person is not insane; but when a hallucination so takes hold of the mind of a person that he is convinced of its reality against the evidences of touch, that person is insane. This lady of whom I have spoken sat in my office, and, pointing to a particular part of the room, said, "There is a stick rising up: it grows out, and now it has on it the head of a big bull-dog." She then went on to describe its heavy, sensual, hanging jaw, vicious expression, etc. She said that she knew that there was no bull-dog there, that she simply saw it as a vision. Then she went on to state that she knew what this meant, that the vision was sent from the other world as a symbol of something that was past. She said, "That bull-dog is given a resemblance to a certain doctor, now dead, whom I once knew. He was a coarse, heavy, sensual man, and this

vision is sent to me to show that his disembodied spirit still holds to the mould of its earthly tabernacle." That woman understood that the thing which she saw had no real existence, and you would at once say that she was sane, but yet she evidently was insane, because she believed that the vision was sent to her as a symbol of something else. She also had all sorts of ideas about a presence at night. She would be awakened out of sleep with a horror and fear that a spirit was behind her. She would at times get out of bed and pray for hours that she might be rid of this presence, which she believed to be the spiritual essence of the devil sent to torment her. She was clearly over the line.

I shall now bring before you some patients suffering with monomania. The first patient is Miss P.

"I understand, Miss P., that you have had a remarkable life. Will you tell us something of your past history?" "Do you mean my personal history?"

"Yes. Tell us something about your life." "When I was brought here I was kidnapped. I was not examined at all. Ever since I was poisoned, which is seven years ago, I have been trying to earn my own living, but there have been parties determined to ruin me. I have not succeeded in getting work because somebody always opposed me. I look upon it as the work of political parties on account of my father's belief."

"What about your ancestry?" "That is what they want to find out. My father was a Stuart, but there are different branches and they are not sure which house it is. There was a mistake made in raising the children and bringing them up among others. This was during the Revolutionary War. My parents lived about the time of the War of 1812. As far as I can make out, both my grandparents lost their lives in this war, and the children were raised among others. The cousins wanted to force me to become one of them, especially one of the Martha Washington descendants. She is determined that I shall live with her, and I can recall many things that she has done with this object."

"Who was it that tried to poison you?" "The party that was implicated said that they wanted to destroy my intellect, but not my life. Something was said about an insane asylum. That was the woman Morris, who is a descendant of one of the parties born on the American side. She is really one of the Marys, and is one of the Jersey links. It is just a fight between some of the American

links and the other links. I am a connecting link between two contending parties. They both have about equal rights."

"Are you happy or unhappy?" "I am naturally buoyant and spirited, but I have passed through a great deal of trouble." (The patient was now removed.)

Gentlemen, you there see an example of what I mean by a thoroughly systematized delusion. That woman argues and reasons about her delusion. You see also that the delusion is not dominated by the emotional condition. She has a mixed delusion. She has a delusion of persecution and a delusion of exaltation. She believes that she is something great, and even has a chance for a throne. That is a delusion of exaltation. She also believes that she is persecuted because of her greatness: thus she has the delusion of persecution grafted upon a delusion of exaltation. The woman's mental functions, disconnected from her delusions, are fairly well performed.

I shall now have a patient brought in who believes that he is Melchizedek the high-priest and prophet.

"Well, C., how are you feeling?" "First-rate."

"You look healthy." "I should like to travel around; I would not mind taking a trip to Harrisburg."

"I see that you have lost your sight; how did that happen?" "I was born with cataracts."

"Does that interfere with your seeing visions?" "Not as I know of. I don't think so. I expect to see a vision of the Lord tonight."

"Have you had such a vision lately?" "Yes. A few nights ago."

"Tell us about it." "The Lord appeared to me in great splendor, in a fiery flame, with a shining face. Take, for instance, that young man sitting up there. What kind of an establishment is this?"

"This is the lecture-room." "Is that so?"

"What did the Lord say to you?" "The Lord appeared unto me and said, 'I am the Lord, thou art my servant.' The institution authorities think I have given up what they call foolishness; but I am still a prophet. I would not object to taking a trip to Harrisburg for my health."

"Are you perfectly well?" "Yes, I believe so."

"Are you perfectly happy?" "Not at present time. I want to be where I can hear the conductor say, 'This train for the east.

Change cars for Harrisburg,' or some other point."

"Do you really see the Lord, or do you only imagine it?" "It is as true as I am sitting here."

"Does he ever touch you?" "No. The Lord does not treat people that way. He stands at a distance, in human form; sometimes just a fiery flame." (The patient was now removed.)

There you see the condition of exaltation with no depressive delusions. You see also that the hallucination goes as far as hearing and seeing, but does not affect the sense of touch.

The next case illustrates a depressive delusion. It is of the melancholic type.

"G., where were you born?" "At Argyle, England."

"Are you married?" "Yes; I have been thirty years."

"What is your business?" "Bricklayer."

"Do you think that you could lay bricks now?" "Yes, I could work, although I have been badly used."

"What have they done to you?" "I have been strangled four times in my sleep. They were trying experiments on me, for what reason I do not know, unless it is because my wife has been here. There are other parties concerned in it."

"Have you seen your wife?" "Yes, I saw her and three others."

"When did you see her last?" "It is about three weeks since I saw the one I took to be my wife. I hear her frequently down-stairs. She has been detained. I hear her sometimes on one side of the hospital and sometimes on the other. Before I came here somebody got into my house and chloroformed me and got at my wife." (The patient was now removed.)

This man probably could work as well as ever, except as his attention was drawn from his work by his delusion. He believes that his wife is perpetually attacked by people, and that she is confined down-stairs. This man represents a very dangerous class. His mental functions are sufficiently perfect to carry out any scheme which may come from his delusion of persecution. He may fasten his delusion on some one and make a violent assault on that party. If this man believed that it was John Jones who had chloroformed him and ill-treated his wife, he would be very likely to assault John Jones. This is practically the most dangerous class of lunatics, and it is the class which is, perhaps, least frequently recognized as crazy.

In concluding this lecture I want to say a few words in regard to the relations between this form of insanity and high intellectual power, and especially with reference to genius. There can be no doubt that a large proportion of those who are considered as the most pronounced examples of genius are cases whose intellects are forever on the border of insanity. To say that an individual is a genius usually means that he has a certain function of the mind exalted high above the other functions. A man whose imagination is developed out of proportion to his reasoning faculties is apt to be a poet or a novelist, and produces works which may live through centuries. Such a man is above his fellows, not by virtue of great brain-power, but because his brain takes a certain limited direction. A man who is dominated by his imagination is always in danger of being swept off his feet by the rush of his imagination. A genius is recognized as a man not practical. By a man not practical is meant one lacking in common sense; and common sense is, after all, nothing more or less than the term used to express good judgment in the ordinary matters of life. A man who has great imagination usually lacks reasoning power, and is not practical, because of his great imagination. One of the best examples of the relation between great imaginative power and monomania is John Bunyan, the author of "The Pilgrim's Progress," which, according to any standard that we have a right to set up, is one of the five or six greatest books in the English language. It is certainly more read than any other book, with the exception of the Bible. No one who reads the history of Bunyan's life can doubt for a moment that he suffered from monomania with depressing delusions. He, however, finally recovered.

Another remarkable instance of the close relationship between insanity and genius is afforded by the famous Victor Hugo. His uncle died insane; his brother, Charles Hugo, in his late boyhood gave promise of remarkable talent for literature, but before twenty he became insane, and finally passed into a condition of complete dementia. One of the daughters of Victor Hugo is now and has been for many years living in an insane asylum. According to the London *Medical Times*, there are in many of Hugo's finest productions numerous passages which could only have been conceived by a diseased imagination, and are indelibly stamped by madness. A remarkable fact in the mental history of

the great French poet is that along with his great imagination there was a shrewdness almost as remarkable. No banker could have more carefully managed his fortune; no politician could have more tenderly nursed his popularity. He who had amassed over a million of dollars died the idol of a communistic democracy; he who had played at fast and loose with all political parties was buried amidst a tumult of universal sorrow.

The prognosis in monomania is exceedingly unfavorable. This is because the condition is so often the result of a faulty formation of some part of the brain. There is a peculiarity of the cerebral organization which shows itself from the very first.

---

*GENU VALGUM, AND ITS TREATMENT  
BY MACEWEN'S OPERATION.*

BY I. FLETCHER HORNE, F.R.C.S.\*

**R**ICKETS holds the foremost place in the production of this deformity. The two chief factors of rickets will be found to be improper food and insufficient clothing, so that among the children of the poor, where the supply of these necessities to the physical well-being is often in inverse ratio to the demand, we find rickets and its resulting deformities rampant.

Genu valgum may exist at birth, or may originate in fast-growing children from want of mother's milk; the non-rachitic form showing itself often during convalescence subsequent to measles, whooping-cough, and scarlet fever, also during the fast-growing period of approaching puberty. We may also see considerable in-knee in robust, tall, over stout, and overgrown adults, height and weight having both contributed to it. In-knee is accompanied for the most part by a relaxed condition of the ligamentous system in general, and is usually preceded by flat-foot.

The ligaments, especially on the inner side of the ankle and those on the sole of the foot, having yielded, the arch of the foot becomes flattened and the foot itself everted: the inner malleolus projects inwards and is lowered, the shaft of the tibia then inclines outwards, the long axis of the femur becomes inclined inwards, the inner condyle protrudes, the internal lateral ligaments yield to the superincumbent weight, and therefore the weight of the body is no longer borne in a

---

\* Surgeon to Beckett Hospital, Barnsley, England.

vertical line and transmitted through the long axis of the femur to the arch of the foot. The femur being thus inclined inwards and the tibia outwards, the condyle of the femur necessarily assumes an oblique position from without inwards.

In its commencement genu valgum is only apparent in the erect position, and is not seen in the horizontal. After some time it becomes permanent; but even whilst the bones are soft, although altered in shape and the internal condyles lengthened, these cases may still be treated by suitable splints. But when the bones have become hard,—and they do in some cases become abnormally hard, almost as ivory,—osteotomy is required.

It is the treatment of the more severe cases, those of children over 10 years of age and adults, to which I would call attention. I think it may be laid down as an axiom that when the structures of the limb have lost their elasticity, the bones consolidated, and impairment of size of the external condyle and the opposite articulating surface of tibia is considerable, and where the patella has left its natural groove and is found outside of the external condyle, and adult age is near at hand, osteotomy is required. I prefer the supra-condyloid osteotomy, as recommended by and named after Macewen, of Glasgow.

A short and ready way to a goal has many attractions, and not the least of the anticipated advantages consists in the saving of time and the appearances of the limb, especially in adults. We must not forget that considerable curvature of the thigh is not incompatible with comfortable use, still I think I may venture to promise, after operation, improved appearance, addition to the height, and, after a time, increased usefulness of the limbs. Aided by the adoption of the quasi-subcutaneous principle, and the beneficent influence of antiseptic dressing, osteotomy for the cure of genu valgum has become one of the most satisfactory operations in surgery.

The operation is done under the steam-spray, Esmarch's bandage being applied to the whole length of the limb to a little above the place of incision. The limb is now placed on a sand-pillow, or, better, a cylindrical wooden block, since the latter offers more resistance, and sand-bags are objectionable in antiseptic operations, to afford an unyielding surface, against which the chisel will act with greater effect. An incision is made one finger's breadth above the tubercle of the adductor magnus muscle on the inner side of the femur; the

incision made is one and a half inches long, down to the bone, being parallel to the femur. The chisel is then introduced, first longitudinally, until it reaches the bone, then turned transversely, and, in cutting the posterior inner part of the bone, should be directed from behind forward so as to cut away from the femoral artery, which passes through the aperture of the adductor magnus above the seat of the operation. From this position the chisel is made to move forwards along the inner border until it comes to the anterior surface, when it is directed from before backwards and towards the outer posterior angle of the femur. When the bone is divided about two-thirds through, the limb is grasped by one hand of the surgeon above the wound, the other holding the leg, and by the use of a little force the bone snaps. The elastic bandage, used to restrain the bleeding, is now removed and any little bleeding points taken up, a pad of gauze is placed over the wound and the splint applied.

The splint Macewen uses is a modification of the half-box, the outer portion being carried up like a long splint to about the third or fourth rib, and it projects beyond the posterior splint at the foot; this projection is fixed in the clamp of a bed-rest, and so the whole splint and limb are kept perfectly firm. The back-piece originally used curved laterally, but I believe now Dr. Macewen has taken to a flat one. I have used both, and I find the flat piece keeps the limb in better position. The thigh and knee are fixed to the outside splint, while the lower limb and foot are thrown inward by abundant padding.

Dr. Macewen says, "If the temperature remains about normal, if there be little pain and absence of discharge, the limb ought not to be touched for a fortnight, at the end of which time the dressing may be removed, when the wound will be superficial and partly covered with epithelium."

The mallet used is of steel; the chisel, or osteotome, used was Macewen's, with blade and octagon handle in one piece, and furnished with a rounded projecting head. The blade is bevelled on both sides so as to resemble a very slender wedge; it is marked in half-inches so that the thickness of the bone can often be ascertained, and thus the distance predetermined. Dr. Macewen recommends three sizes of chisels, but in my hands one has answered well for all my cases.

CASE I.—T. D., aged 9, admitted to Beckett Hospital from the Union Workhouse with double in-knee, the feet separated twelve

inches when he stood erect, and he walked very awkwardly.

*January 9, 1885.*—I performed Macewen's operation on right leg with antiseptic precautions; no hemorrhage. The dressing first removed January 26; there was slight suppuration and a slight superficial slough.

*February 24.*—The splints were removed. On measuring the limb from the anterior spinous process to the inner malleolus, the right leg measured twenty-two inches, the left twenty-two and one-half inches; the right leg was put into plaster of Paris bandage. February 27 the patient was again put under ether, and with the spray and antiseptic precautions the operation was performed on the left leg; there was no hemorrhage; the wound was dressed with McGill's silk.

*February 28.*—Slight rise of temperature, reading 100° F., but afterwards throughout the case the temperature was normal. The wound was dressed March 26, when there was good union; the limb was put up in plaster of Paris bandage.

*June 19.*—Discharged. The boy can walk with the aid of crutches; the legs are equal length and straight.

*November 19.*—I saw the patient to-day; the legs have not shrunk, are perfectly straight, and he walks exceedingly well.

CASE II.—Eliza B., aged 16, was admitted under my care February 23, 1885, suffering from genu valgum of a very marked character. The patient was short and stout, with a satisfactory family history. The in-knee was more marked in the right than the left leg, and considerable enlargement of the lower epiphyses of both femora; no curvature of tibia or other bones. When the knees were closed there was a distance of ten and one-half inches between internal malleoli; the patient walks very badly and is easily tired.

*February 27.*—The patient was placed under ether. I divided the left femur after Macewen's method, under spray; I used wire sutures for external wound, which was dressed with McGill's silk.

*February 29.*—Temperature rose to 100° F., but very slight constitutional disturbance. The wound healed slowly, a small ulceration remaining for some time. April 19 the limb was put up in plaster of Paris bandage; good union; length from anterior superior process to internal malleolus, right, twenty-seven inches, and the left, twenty-six inches.

*April 17.*—Operation was performed on right leg, using catgut sutures and Lister's gauze dressings.

*April 19.*—Temperature 100° F. Wound healed rapidly; only dressed three or four times. May 25, plaster of Paris bandage applied. The right leg united in a perfectly straight position, but there was a sharp angle left on the outer side of the fracture. The patient had several attacks of tonsillitis with enlarged glands during the month of May.

*June 19.*—The apparatus was removed, the legs being quite strong, ankles and knees touching, and was able to walk with crutches.

*November 23.*—Examined the patient again to-day; legs perfectly straight. She told me she had walked three miles the day previous without being tired.

CASE III.—H. K., admitted March 30, 1885, suffering from genu valgum. The patient was a flabby, unhealthy-looking lad, tonsils chronically enlarged, teeth irregular, and the ribs rickety. There was a well-marked genu valgum of right leg, with large lower epiphysis to femur, especially on the inner side, also slight genu valgum on left leg; length from anterior superior spine to external malleolus, right, twenty-three inches, left, twenty-three and one-half inches. When the knees were in apposition the distance between the malleoli was six inches.

*April 1.*—Under ether and the usual antiseptic precautions the operation was performed on the right leg. May 4 the wound had healed, the knees and ankles are in apposition, and the patient's health has considerably improved, there being no difference in the length of the limbs. The right leg was placed in plaster of Paris bandage.

*May 12.*—The bone has become firmly united, the tonsils were excised by guillotine, and he was discharged on the 20th inst.

The temperature rose to 100° F. on the evening of April 1, and again on the 4th and the 8th it rose to 102° F., and on the 9th of April it rose to 101° F., but from no apparent cause.

CASE IV.—S. M., aged 19 years, miner, was admitted May 16 with synovitis of right knee. The patient was unable to stand, except by holding on to furniture, from an injury received in the colliery a year before; this prevented him from earning a livelihood. The synovitis subsided under treatment, and it was found he had a well-marked genu valgum on the right leg, and the internal condyle was increased enormously in size, with the sharp corners almost projecting through the skin. On the left leg he had an extensive curvature of the tibia, which was treated by osteotomy.

*July 24.*—I performed Macewen's operation on the right thigh; catgut ligatures were used for outside wound. The wound was dressed only once, and on the 3d of August was quite healed. The exostoses of bone were removed at a later period.

The advantage of Macewen's operation over those of Ogstan, Reeves, and Barwell consists in the greater simplicity of the operation, and the freedom from danger to the joint. After the operation, nature fills up the triangular cleft in the femur. The outer side of the limb is apparently lengthened. It assails the insufficient external condyle by depressing it to its proper place and the articular surfaces of both condyles to their proper plane.

The four cases of osteotomy which I have narrated above go to prove the slight constitutional disorder set up by an operation of some magnitude, the great improvement that may be brought about in the personal appearance of patients of this class, and the turning to good account the usefulness of the limbs themselves, whilst last, but not least, may we not infer that this operation is a distinct advance in the art of surgery?

*ON THE INFLUENCE OF AGE ON THE  
DOSAGE OF NUX VOMICA, WITH  
SOME REMARKS ON ITS  
THERAPEUTICS.\**

BY J. H. MUSSER, M.D., PHILADELPHIA.†

IT is believed that the following facts regarding nux vomica are not generally known or not fully appreciated by the profession, and that, as far as the writer knows, one of them is entirely new. I refer to the influence of age on the dosage of this drug. The only reference to this important matter that I am aware of is in the last edition of Wood's "Therapeutics," where it is stated that young animals have been found to be less susceptible to the drug than old ones.

A shrewd medical man observed to the writer, some time ago, that he could never get much service from nux vomica except in the aged. Upon endeavoring to find the reason for this it occurred to me that possibly, as with many drugs, the susceptibility to its influence increased with the age of the patient. Opportunity has been afforded me to test this

surmise, and I can affirm that repeatedly in the out-patient department of the University Hospital its truth has been demonstrated. It is with pleasure I can record that many of my students and my former assistants, Drs. Fussell, Mercur, Emery, Dock, Allyn, and others, can corroborate these statements.

The preparation of nux vomica used was the tincture,‡ and most of the experiments were made with the solution of the Pharmacopœia of 1870. As is well known, it is about one-third stronger than that of 1880.

The maximum dose at any age was not administered, but the usual dose commenced with. This was done, and should be done, to guard against dangers that may arise from idiosyncrasy or cumulative action. Beginning, therefore, with 10 drops three times daily, it was the custom to increase it 3 or 5 drops every second day until some physiological effect was produced, as twitching of some group of voluntary muscles. As soon as this effect was produced the dose was reduced one-third, and in a few days, especially if desirable to produce full effects, ascending doses were again administered. They could invariably be increased beyond the former limit.

Going over the notes of some fifty cases, I find that at from 15 to 40 years of age 45 drops or more of the tincture was almost invariably well borne. After 40 years it was the exception to be able to increase the dose over 35 drops without causing some disagreeable symptoms. In all my cases extreme susceptibility was not observed. Six had apparently no influence on the size of the dose.

One of the patients, aged 24, took 200 drops three times daily with most decided benefit. To another, aged 16, 125 drops were exhibited without experiencing any bad effects. On the other hand, a male, aged 60, could take but 20 drops, and not one over 50 could get beyond 35. Patients aged 16, 24, 28, 35, and 40 took 40, 55, 30, 45, and 45 drops respectively before any therapeutic benefit could be seen.§

At first sight it would appear that the above were unusually large doses. When one remembers that there is about  $\frac{1}{100}$  of a grain of strychnine in five minims of the tincture of nux vomica, the dose seems not so great. My observations have taught me that with the usually prescribed dose we can get, in most

\* Read before the Philadelphia County Medical Society, January 13, 1885.

† Physician to the Medical Dispensary of the Hospital of the University of Pennsylvania, etc.

‡ For obvious reasons it is not safe to dispense strychnine or other alkaloids in the promiscuous crowd of out-patients, especially as the druggist must dispense rapidly.

§ I do not refer to paralytics, etc., for to these people, even in advanced life, large doses can be administered.

cases, but little results beyond what arises from its local action as a bitter; moreover, what effects we may secure are transient unless we increase the dose. The system readily becomes accustomed to its stimulation.

It is well known that neurologists and ophthalmologists push this drug in a similar manner, but I do not know that ascending doses have been used at the hands of others in cases similar to the ones hereafter to be referred to.

Two effects of large doses of the drug were observed that, under certain circumstances, would be disadvantageous,—the production of diarrhoea and of frequent seminal emissions. Small doses of laudanum would readily control the former, although it is rare that the case would demand such very large doses. The latter symptom could not well be remedied.

*The Therapeutics of Nux Vomica.*—Nux vomica is eminently of service, according to my experience, in dyspepsia of the atonic variety, with or without depression of spirits, hypochondriasis, headache, weight on the head, and other nervous phenomena. It is in these cases that increasing doses are of value. I believe this good effect to be due not alone to the local irritant effect of the drug, as suggested by Ringer, nor to its tonic influence on the muscle and blood-vessels, but to its systemic effect, whereby reflex excitability of the spinal and vaso-motor centres is increased. Digestion is eminently a reflex process. This is seen from the efforts of mastication, throughout the entire process, to that of defecation. Now, it seems to me that atonic dyspepsia and slow digestion, with the train of morbid symptoms that arise therefrom, are due primarily to torpid nerve-centres. They do not respond to the stimulus of food, and hence refuse to send the requisite amount of blood to the glands by virtue of their influence on the vessels, or to stimulate glandular secretion. In fact, this element of diminished reflex excitability may be present, and it seems rational to think so, in all forms of dyspepsia, whether from general debility, the excessive use of indigestible articles of diet, or of stimulants. In these cases it is requisite to get the full effect of the drug. Likewise, in the dyspeptic symptoms that belong to heart-disease, bronchitis, or cirrhosis of the liver, the good effects of nux vomica are no doubt on account of its tonic effect on the blood-vessels. In gastric catarrh, on the other hand, small doses of the drug should be used to secure its local irritant action. It

seems to me the same theory, the increase of reflex excitability, may partially explain the good effect of this drug in constipation.

As a respiratory stimulant the action of this drug is well known. I once ordered it to a young girl in doses of 20 drops, and was surprised to find her father had had the bottle replenished twice for a cough. On the occasion of his third visit he confessed it was the best cough mixture he had ever had. Emphysema and chronic bronchitis were the cause of his cough. Last winter the nux vomica kept at work the entire season and enabled to walk long distances a man who for years previously would lose weeks and weeks each season on account of asthma and emphysema. His "wind" improved wonderfully, and his great boast was his ability to walk home with his fellow-workmen at their gait. I could readily repeat many instances of the value of this drug where respiratory stimulants are indicated.

In mental and physical depression due to prolonged excitement this drug is of value. One of my students took from 600 to 800 drops daily of the tincture, and thereby successfully tided himself over a period of great strain. In fact, he studied harder and kept later hours than at any other examination period, and with less detriment to his health. He is myopic and astigmatic, and this was the first time he came out of his studies without suffering from eye-strain. The doctor writes me that he has used the drug since in practice under similar circumstances. For instance, he helped along well a young society girl, who was unusually busy with engagements, until the rush was over. The uses of the drug are as dangerous, however, as the use of any stimulant, and should be given only on extraordinary occasions for the purpose indicated. Its use as above serves to show its power as a nerve-stimulant.

It has recently been the custom of students of medicine to take caffeine to keep them awake for study. My observation of the students who had taken one of these drugs was favorable to the use of nux vomica. The ones who took it came off with much better health and less nervousness than the caffeine-eaters.

Many patients complain of being more tired on rising in the morning than when retiring. This has disappeared frequently on a course of nux vomica. I have also the records of cases of spasm of the œsophagus, of excessive flatulency, of nervous depression, characterized by fear, by ready excitability, by mental lethargy, irritability, etc., and of forms

of hysteria,—occurring late in life especially,—which were improved by this drug.

There are, of course, other well-known uses for this valuable drug which time and space will not permit me to detail. In small and frequently-repeated doses it has been recommended to be used, but I confess I have never had any good results from its use in this manner. Ringer recommends it in acute gastric catarrh, with "sick headache" and slight nausea, only in doses of 1 drop, in water, every five or ten minutes, until eight doses are taken. It may be a mere coincidence, but nevertheless in every instance of a similar character in which I used it, it caused vomiting without any relief.

The following are some of the conclusions which may be drawn from the above statements:

1. The effects of *nux vomica* are in inverse proportion to the age of the patient; the susceptibility increases with the age.
2. The usual doses of the tincture indicated in the text-books are inadequate for many practical purposes, and do not represent the usual dose of strychnine.
3. It is a powerful and rather transient stimulant.
4. The best therapeutical effects can be secured in many cases only by pushing the drug almost to the physiological dose.
5. The system soon becomes accustomed to its use, and the dose must be increased.
6. The good effects in dyspepsia are largely due to its power to heighten reflex excitability.

#### PALATABLE THERAPEUTICS.\*

BY FRANKLIN H. MARTIN, M.D., CHICAGO.†

**N**OWHERE in medicine is the strong hand of radical reform more needed than in therapeutics. An innovation of a radical nature in the field of *materia medica* or *therapeutics* has, until lately, been looked upon as something little short of irreverence. It seemed to be a foregone conclusion that the old traditions with their long lists of nauseous and incompatible boluses, infusions, decoctions, tinctures, extracts, powders, salts, pills, oils, blisters, etc., must be religiously guarded

from the insinuating finger of reform. A new curative method or a new theory of administration was very liable to be condemned as quackery. The present state of scientific thought, however, with its intense light, is gradually dispelling this fog of exclusiveness, and even in therapeutics we begin to feel that we are out of darkness.

We now freely admit that many of therapeutics' greatest strides have been the outcome of suggestions gleaned from the fields of charlatanism. We have been led at a late hour to recognize the advantages of faradic, static, and galvanic electricity as a therapeutic agent, and to place it upon a legitimate and scientific basis. Massage and "Swedish movement" have been recovered from the same questionable ground, and have fast become valuable adjuvants to our curative list. And upon going back over our long list of vegetable, mineral, and animal drugs, we find that the majority of them were born in barbarism, and from their obscurity were made prominent by the hand of the busy empiric, and by a justly-earned reputation have forced the doors of our pharmacopœia. Thus by investigating and appropriating in all places we have increased.

While we have pursued our explorations in the fields of medicine and established therapeutics upon a more scientific basis by means of improved methods of investigation, while we have isolated new remedies, established new principles, and developed new theories, have we not neglected too much, some of us, to bear in mind the practical fact that to be successful and humane practitioners of medicine we must consider the peculiar tastes of our patients as well as the scientific application of our remedies to disease? While it is gratifying to *us* to know of a certain drug its *modus operandi*, it is gratifying to a long-suffering *patient* to have that drug administered in a palatable form.

Herein lies the secret of success of that unscientific and utterly irrational dogma of Hahnemann—homœopathy. The so-called remedies of homœopathy are tasteless because of their infinitesimal division. On account of their palatability they are popular with that class of patients who will not tolerate nauseous drugs, and who are not educated to the point of appreciating the utter fallibility of homœopathic so-called remedies. There is not a regular practitioner of medicine who has not been annoyed by some misinformed patient persistently asserting that the only difference between regular practice and ho-

\* The substance of this paper was read before the Chicago Medical Society.

† Fellow Chicago Gynecological Society, Clinical Lecturer in Gynecological Department of South Side Dispensary, Member of Chicago Medical Society, etc.

mœopathy is that the former includes all those drugs which are unpalatable and strong, while the latter all that are palatable and mild. Judging from prescriptions that we often see, we cannot but admit that there is some reason for this unjust conclusion.

We can learn one very important lesson from this unfortunate state of affairs. We find homœopathy, possessing absolutely no merit, succeeding because of three qualities of a nature which demonstrate its weakness. These qualities are palatability (because of infinite division), harmlessness (because of inertness), cheapness (because of lack of substance). If a system of medicine can conceive, survive, and thrive upon these negative qualities alone, how much more could be accomplished by *true* medicine, possessing the accumulated merit of all time, if it would adopt as far as possible these requisites of homœopathy as adjuvants of its system of administration!

The object of this paper is to discuss, without making any claims to originality, the means by which we can avoid offending the palate of our patients while administering and receiving all the advantages of our many efficient remedies.

**Alkaloids.**—Hahnemann made all medicines palatable by infinitely dividing them. We can make many of our medicines palatable by concentration. In this department very much is constantly being accomplished by chemistry and pharmacy. The key to a great work in this direction was discovered in 1817, when Sertürner, a German apothecary, announced the existence of morphine. This gave an impulse to organic chemistry which has been, and will be, of inestimable value to pharmacology. Since that time a large number of alkaloids have been extracted, many of which have already taken prominent places in medicine as substitutes for original bulky drugs. These vegetable alkaloids usually possess a definite physiological action nearly resembling the action of the parent drug. They have a definite chemical composition, and with acids form salts. They possess, therefore, the very desirable properties of uniformity and adaptability. Representing, as many of them do, all the medical virtues of the crude drug from which they are extracted, in them we have a very concentrated and uniform substitute. By improved pharmaceutical methods these concentrated alkaloids can be divided into representative doses, made into small granular masses with proper excipients, and thoroughly disguised by a

thin coating of tasteless and readily soluble gelatin or sugar; thus making an elegant and perfectly palatable dose of uniform strength, of definite composition, representing what in the old galenical preparation of the crude drug would have been nauseous, ununiform, and disgusting.

Already about twenty-two of our most prominent drugs are represented in their alkaloids in these little masses, each contained in an elegant gelatin or sugar sphere one-sixteenth to one-eighth of an inch in diameter.

**Glucosides, or Neutral Principles.**—Besides the alkaloids there are certain proximate vegetable principles which are of great value to us as palatable therapeutists. They are of definite and uniform strength like alkaloids, and many of them, like the alkaloids, represent the medical properties of the vegetable from which they are extracted. They are classed as *glucosides*. Amygdalin, the first principle of this kind isolated, was discovered by Liebig and Wöhler in 1837. In the great march of organic chemistry the glucosides have not been neglected, and we find that about twenty of our valuable vegetable drugs are as well represented by these neutral principles as the alkaloids represent all that is of medicinal value of their particular source. These principles are usually in the form of crystals, or amorphous powder, and represent in many cases the full medicinal value of the vegetable from which they are extracted in a very concentrated and uniform shape. They are, therefore, rapidly occupying a prominent place in our therapeutics, and becoming as popular as their worthy rivals,—the alkaloids. As stated above, about twenty of these glucosides have been tested and arranged, and already, by the enterprising pharmacists, have been manufactured into gelatin- or sugar-covered granules of appropriate doses.

Thus we find that we can get the full result of the physiological action of forty of our most powerful and valuable drugs represented in their *active principles*, the alkaloids and glucosides. They represent the properties of the mother-drug free from all extraneous matter,—*concentrated, uniform, and absorbable*.

Unfortunately, however, this branch of pharmacology is in its infancy, and many alkaloids and glucosides are still locked in the mysterious womb of the mother-drug, and until they are searched out and delivered we must adopt other means of making palatable our doses.

**Solid Extracts.**—By means of extracts freed

of all unnecessary extraneous matter we can administer many drugs palatably by adopting the gelatin capsule and the gelatin pill. Since the nauseous uncovered pills have been displaced by absolutely tasteless gelatin- and sugar-coated ones, the old popular abhorrence of this method of taking medicine has subsided into a pleasing indifference. Pills of a reasonable size are no longer objected to. The smaller-sized capsules are becoming very popular with both patient and physician. They have been the means in my hands of allaying the prejudice against the "Old School" of more than one homœopathic adherent. By means of these capsules the practitioner can, by the exercise of his ingenuity, administer a great many valuable but nauseous doses to the most delicate palate. The gelatin-coated pills will also be of advantage to the physician in administering well-tryed combinations as well as single remedies. We have been given in the last Pharmacopœia thirty-two reliable solid extracts, which represent the majority of our most valuable vegetable drugs. The full medicinal effect, with few exceptions, can be obtained from these drugs by administering their extracts, palatably and elegantly stored away in these little capsules. Besides the extracts, there are a great number of other drugs that can be administered in the capsule or the tasteless pill. The salts of the various metals that are administered internally can be administered in capsules, or the pill or granule. The bromide and iodide of sodium and potassium are suited for capsules. The powdered salt can be given in doses of from 2 to 5 grains in capsules that can be readily swallowed. It may be necessary in some cases, after giving large doses of these salts in capsules, to follow them with a small quantity of water, in order to dilute the salt as it becomes free, and before it comes in direct contact with the mucous membrane of the stomach, as otherwise irritation of the stomach is caused.

If one is really desirous of making medicines palatable, his ingenuity will suggest many drugs that can be represented in pill or capsule that ordinarily are put into vile combination in mixtures.

*Tasteless Salts.*—There are a number of salts and combinations that are practically tasteless that can be administered palatably in powder or dissolved in small quantities of water. In our last Pharmacopœia I find ten that can be given in teaspoonful doses of water. Tartar emetic is a fair example of this class. There are eight that can be given

as tasteless powders in small doses. Of these calomel is an example.

*Tinctures and other Tasteless Solutions.*—Quite a list of our tinctures can be given in palatable and appropriate doses by mixing with drachm doses of water. This makes a very elegant and at the same time effective method of administering tasteless tinctures, and deserves to become popular. Of the tinctures recognized by the Pharmacopœia eight can be administered in this way. Tincture of gelsemium and tincture of aconite may be mentioned as examples. It is a fact worthy of note that many of our tinctures that are now unpalatable are so because of extraneous matter they contain, which might by proper methods of preparation be extracted and eliminated without affecting the medicinal value of the drug. Fowler's solution is an example of a chemical solution that is palatable and can be given in small doses of water. I find six similar solutions that can be rendered palatable in the same way.

*Oils and Oleoresins.*—Until of late the most difficult problem to solve in palatable prescribing was the administration of the oils and oleoresins. They are of great value to our armamentarium, and indispensable to complete medicine. In the uncovered state they are the most abhorred drugs, even by the staunchest friends of regular practice, that our list contains. Castor oil, cod-liver oil, turpentine oil, olive oil, and copaiba have been the means, no doubt, of converting a multitude to homœopathy. To our enterprising pharmacists at last our thanks are due for no longer being obliged to insult the stomach and disgust our patients by insisting that they pour down these greasy nauseates. The *flexible elastic capsule*, first put into practical form by our large pharmaceutical firms, is bound to become very popular as a means of administering the oils and oleoresins. One large Western house (Parke, Davis & Co.) has manufactured these capsules and filled them with sixty-seven different formulas. The responsibility rests with the physician to see that these valuable suggestions, that are put into practical form by well-known and reliable pharmaceutical houses, are taken advantage of and made requisite of our practice. These soft elastic capsules are manufactured in all sizes from one-half ounce down to two minims. They are easily swallowed, and afford complete palatability.

*Acids.*—We have disposed of the majority of our valuable drugs, still we have a few that it is necessary to occasionally employ that can-

not be administered in granules, in pills, or any capsule. Among these we get the acids. The acids, while they cannot be administered as tasteless remedies, can, by proper dilution, be made palatable. A small dose of well-diluted acid in properly flavored and sweetened water is often taken with relish. Where we find it necessary to give acids, by adopting this method, protecting the teeth by the use of a tube, much will be done toward popularizing the acids. It is better to give small, often-repeated agreeable doses, and retain the good-will and co-operation of the patient, than lose control of all by the opposite course.

Thus it is easily seen that with ingenuity and tact about all the effects that are to be obtained from the administration of drugs can be obtained without offending the palate. Especially when we have considered the numerous channels through which medicines can be administered other than the mouth will this seem feasible. And before closing I wish to make a plea in this direction. Many nauseating doses are spared by the judicious use of suppositories, by the appropriate use of the oleates, by the proper use of enemata, and by the elegant and prompt effect of the hypodermic.

It will be claimed by some, when prompt action is necessary, that pills and granules and capsules will not be so rapidly absorbed as remedies in solution. Where promptness is the desired effect, the hypodermic syringe is the means *par excellence*, and, by proper use, will accomplish all that is desirable in that direction.

We can summarize, then, the means by which the regular profession can administer, and obtain all the effects of, their remedies without offending the most delicate palate under the following heads:

1st. Administration of the *alkaloids, neutral principles*, and other drugs of *small bulk* in *gelatin- or sugar-coated granules*.

2d. Administration of *solid extracts, crude drugs of small bulk*, and the various salts in *pills of gelatin or sugar and gelatin capsules*.

3d. Administration of tasteless tinctures and other tasteless liquids alone or mixed in water.

4th. Administration of the *oils, oleoresins, oleates*, and drugs soluble in oils in *elastic capsules*.

5th. Administration of acids well diluted in sweetened and properly-flavored water.

6th. Administration by hypodermic injection, by suppositories, by enemata, and by inunction.

Thus we have, imperfect though it be, a system of palatable therapeutics. I am far from being *entirely* satisfied with it. I am convinced, however, that it is capable of being gradually developed to perfection. I believe it would be to the interest of our system, unsatisfactory as it at first might appear, if each of us would constitute himself a nucleus for a vigorous reform in this direction.

We cannot with proper dignity attack homœopathy in any other way. We recognize in it an adversary as aggravating as it is utterly devoid of scientific merit. We cannot kill it by fighting it, but we can sink it into insignificance by improving ourselves.

2139 WABASH AVE.

### THE CULTIVATION OF COCA.

BY HENRY H. RUSBY, M.D.

FOR more than two months the writer has been continuously engaged in the study of the coca-plant and its products in the districts of Bolivia which produce the best quality of leaves. The results, which are likely to greatly increase the recently-created interest in the plant, will be published shortly, when his studies shall have been concluded. At the present time I will only discuss a question concerning which speculation is rife, namely, the adaptability of the plant to culture in countries where it is now unknown.

For the details concerning cultivation here presented I am chiefly indebted to Mr. Oscar Lohse, one of the most intelligent cultivators in this country, and proprietor of the Finca of San Antonio, two leagues from the town of Caroica, Yungas.

The district of Caroica may be considered as fitly representing the remainder of Yungas, and Yungas as representing the principal coca districts of this republic. The conditions of soil and climate may be briefly stated. Proceeding eastward from La Paz, itself somewhat more than ten thousand feet\* above the sea, for a distance of four or five leagues, we reach the summit of the pass over the easternmost cordillera of the Andes, this cordillera having an average elevation in this immediate district of perhaps sixteen thousand feet. This ridge, always more or less snow-covered, cuts off a large portion of the westward-bound clouds, which are thus either

\* I have given altitudes and measurements approximately in English feet. By the Spanish measurements the altitudes are much greater.

precipitated in the form of rain before reaching the summit, or, arriving there, are deposited in the form of snow, and then returned by means of rivulets to the valleys, chiefly of the eastern slope. It should be noted that in Northern Peru and Ecuador this cordillera is higher than here, so that the eastern slope in those regions is more profusely and regularly watered than here. From this pass, had we a direct road, we could travel in half a day, so steep is the descent, to the banks of the Carouca River, having an altitude of only two thousand four hundred feet. When we have descended to six thousand four hundred feet we should meet with our first coca plantations, and after passing the two thousand foot level we should have left them principally or entirely behind. Within this four or five thousand feet, then, lie the cocaes of Bolivia. No description can convey a perfect idea of the steepness of this luxuriant slope. Travel, entirely by riding-animals, is extremely difficult. There are only occasional places where we can readily leave the road, and here plantations are established. The hedge of coffee-plants at the roadside proves on examination to be the uppermost row of a plantation; and as we peer down among the shrubs we marvel that any one can preserve his footing while cultivating or collecting the coffee. The scenery is of course magnificent, and of a different type, I should think, from that of any other part of the world. The mountains are too young to have lost, to a great extent, their ragged outline, yet softness is imparted by the richness of the vegetation. We stand among the coca-plants and distinctly see another cocal nearly four thousand feet below us.

As there is no better guide to the agricultural capacities of a country than its native plants, I will mention the characteristic classes. At the pass, with an altitude of about thirteen thousand feet, we have but little vegetation,—this low and mat-like, to escape the cold and the winds. Crossing, soon after, a spur having an elevation of one or two thousand feet less, we meet with several Gentianaceæ, notably a *Halenia*, believed to be *H. Rothrockii*, Gray, of New Mexico. Here, also, are some shrubs in Acanthaceæ and Bignoniaceæ. At nine thousand feet we begin to find Orchids and Calceolarias, with some small trees in Melastomaceæ. At eight thousand feet we meet with our first tree-ferns; the timber-trees become quite large, and Begonias begin to make their appearance. From this point the vegetation begins to assume a really tropical aspect.

We find many species of Calceolaria, Fuchsia, and Amaryllidaceæ, while the variety of orchids and ferns is quite bewildering. At six thousand five hundred feet we see the first palms, and the forest-trees become buttressed giants, staggering under their loads of vines and climbing aroids and ferns, and their branches covered with Bromeliaceæ, orchids, and other parasites. Seventy parasites have been counted upon a single fallen tree.

The cultivated plants of the coca district are coffee, rice, cacao, sugar cane, tobacco, maize, cotton (the arborescent species), sweet potatoes, yuccas, and the ordinary garden vegetables. The principal fruits are oranges, bananas, cocoanuts, lemons (sweet and sour), citrons, grapes, chirimoyas, alligator-pears, tumbas, pomegranates, grenadillas, figs, papayas, lukmas, melons, and pineapples, the last just introduced.

The soil in such a broken country is of course very diversified, ranging from a very light decomposed shale or sandstone to a heavy blue or chiefly yellow clay.

The rainy season begins in October, and continues until May or June. During this time the rains are copious and almost constant. During the succeeding two months there is scarcely a drop of rain, and during the next two there are only occasional showers.

Such are the conditions under which the coca grows in this section.

When we come now to consider the methods of cultivation here adopted, we must be cautious about accepting them as the best, merely because they are generally followed here. It is to be remembered that the Bolivian system of agriculture has not received the attention that it should have had, and that it is very probable that reforms might be introduced in present methods.

Nor is it proper to proceed concerning coca-culture without a few words concerning what is meant by the "best quality" of coca-leaves. To a manufacturing chemist the best quality would mean the quality that would yield the largest percentage of crystallizable cocaine, obtainable in the easiest manner, while the same coca might be considered for domestic consumption as representing one of the lower grades. It is highly probable that the amount of cocaine forms no element in the Indian's estimate of the quality of coca, no more than the percentage of nicotine establishes the quality of a particular grade of tobacco. Coca-leaves are classed in general by the Indians as "hajas dulces" (sweet

leaves) and "hajas amargas" (bitter leaves). The former are made sweet by the abundance of alkaloids other than cocaine. While it is true that a greater abundance of those alkaloids is usually accompanied by a larger percentage of cocaine also, yet the variation in the amount of the latter is not so great as in the former; so that while in the sweet leaves the bitter taste of the cocaine is masked by the presence of the other alkaloids, in the bitter leaves its flavor is the predominant one. The presence, then, of these *sweet alkaloids*, as we may call them, translating the simple and expressive term of the Indians, determines the domestic value of the coca, and all that is known of the best methods of cultivation is based on the production of the highest percentage of these alkaloids. Experience may determine that for manufacturing purposes a very different line of principles of culture should be followed.

I have made a large number of assays tending towards elevations, soils, exposures, seasons, ages of plants, and of leaves, different varieties, wild and domestic, different parts of the plant, and various modes of drying and packing. The results will be embodied in a future monograph, mere passing references being made to them for the present. I have about concluded that the percentage of the sweet alkaloids varies inversely as the amount and continuousness of moisture that the plant receives. Thus, the Peruvian, Ecuadorian, and Brazilian coca, which, as I have stated, is much more copiously and regularly watered than the Bolivian, is markedly inferior, so that Bolivia regularly exports about one-eighth of her crop to those countries. I am inclined to think that the greater breadth and thinness of the northern leaf may be partly due to the greater water-supply and the consequent greater degree of evaporation. Again, the Indian always seeks the coca grown at the higher elevations, where the humidity is much less and more irregular than in the districts along the rivers. We are thus obliged, for reasons to be elaborated in the future, to regard these alkaloids as preserving a sort of a balance of moisture, by which the plant stores up during the wet weather a concentrated supply of water, which may be very slowly yielded up during a time of need.

Having thus chosen a high altitude, the next thing is to select a soil. A rivalry exists between a yellow clay and a hill-side soil rich in vegetable matter. My assays have yielded the best results (as to total alkaloids) from

soils of the latter class, and I am inclined to think that those who prefer the former soil do so because it yields a somewhat larger crop.

The ground for the nursery-bed is prepared during the latter part of the dry season by breaking it up very thoroughly to the depth of a foot or more. The fruits mature during the early part of the rainy season, December and January. They are red, and consist of a fleshy outer portion and a shell-like inner portion, which encloses the single seed. These people suppose that the germ cannot escape from the shell if planted in its natural condition, and they have continued for hundreds of years to deposit the seeds as soon as gathered in a shaded place, in layers an inch or more deep, and covered with a thin layer of decaying leaves or similar substance. The heat generated by the decomposition of the fleshy pericarp serves to induce germination, and the embryo bursts from its bony covering. This growth unites them, in from eight to fourteen days, into a solid mass, which is broken up into small pieces and planted in furrows in the nursery. In this process very many of the sprouts are broken off and the plants destroyed. Mr. Lohse has adopted the plan of sowing the seeds broadcast as soon as gathered, and covering with a little earth, or, better, a layer of banana-leaves or other decaying vegetable matter. Germination requires from eight to twelve days longer, but all the plants are saved. In either case a covering of brush or straw must be placed over the nursery, at first only three or four inches above the surface, and elevated to six or seven inches as the plants grow. Usually this elevation is repeated once more.

All this taking place during the rainy season, the plants have reached a good size before the advent of the dry weather, and so do not call for any artificial water-supply. Advantage is taken of the ensuing dry season to clear the land and prepare the ground for the new coca. On the manner in which this is done depends much of the future well-being of the plants. The ground should be thoroughly powdered to the depth of two, and, if possible, three feet, all roots and large stones being removed. On these steep slopes it is necessary to terrace, the terraces being supported by stone walls, the stones laid dry. The width of the terraces, according to the slope, varies from several feet, with a number of rows of plants, to much less than the height of the wall, only a single row of plants being admissible. It is here generally believed that

shade tends to the production of the best quality of leaves; so the cocales are planted thickly with a small broad-topped leguminous tree related to the St. John's bread, but whose name I cannot at this moment recall. There is no doubt that this is a mistake. I have made repeated comparative assays of shade-grown and sun-grown leaves from adjoining plants, and invariably found the latter much richer in total alkaloids. I judge the custom to have arisen from two considerations. There is, as I have stated, a period of two or three months when the plants receive no rain, and then these trees afford a protection from the fierce heat. Secondly, shade conduces to the production of a large, smooth, beautiful leaf, of elegant color, and thus adds to the *appearance* of the product. The terraces being thus prepared, on the advent of the permanent rainy season the plants, now from eight to twelve inches high, are transplanted, being set from one-half to six inches apart, according to ideas of the haciennero. From this time until the first leaves are picked the greatest care must be taken to keep the soil thoroughly stirred and free from weeds. The plants having been transferred in October or November of one year, the first picking is made in March or April of the second following year, one year and a half from the time of transplanting, or two and one-half from the seeds. In case an insufficient space has been prepared, the remaining plants are often left until the following year, and then transplanted, the operation being much more dangerous to the life of the plants.

The chief danger of picking the leaves earlier than the period indicated above is not the strain upon the vitality of the young plant, as many of the leaves drop of themselves, but because it is almost impossible to avoid breaking off the very tender tips of the twigs, the result being fatal to many plants. Immediately after this first picking, fresh leaves develop with great rapidity, and in July or August of the same year the plant flowers for the first time. The lovely white flowers, if undisturbed, remain for from three to six days; but from the very first they are dislodged by the slightest jar, the corolla falling entire, although it is morphologically poly-petalous. The fruit ripens in December and January.

During the first few years the percentage of alkaloid increases rapidly, reaching its maximum at or before the age of ten years. At the age of twenty it begins to diminish, but with extreme slowness, so that the plants

are practically in their prime up to the age of thirty-five or forty. It is probable that the decline is then due rather to the exhaustion of the soil than of the vitality of the plant. Fertilization of the soil has never been resorted to. It is probable, as suggested by Mr. Lohse, that as much can be done for the coca in this way as has been done for other plants.

A coca harvest is called a *mita*, an Indian word meaning a division or drawing of lots, and there are from three to five in a year, according to the season. The time of picking is determined solely by the condition of the leaves. When they have become mature they turn yellow if in the dry season, and brown if in the rainy, and within eight days at the outside will fall to the ground and be lost. As soon as the *mita* is over, the ground is cleared from weeds, and, under an ignorant notion that further cleaning is injurious, is left undisturbed until after the next *mita*. But Mr. Lohse has tried the plan of keeping the ground clean, with the result, thus far, of receiving the next crop in little more than one-half the time required by his neighbors. No irrigation is resorted to during the dry season. Although it is possible that good might result, at least to the welfare of the plant and the size of the crop, I suspect that after a long time an abundant and steady supply of water would result in a decrease in the amount of alkaloids. Mr. Lohse has tried the experiment of mulching at the end of the wet season with a few inches of banana-leaves or other refuse, with excellent effect upon the plants during the succeeding dry season.

This plant is subject to only two diseases of any importance. The first is *taja*, which I suppose to be the result of a fungus which attacks the undeveloped leaves and tender twigs. It is said by some to be caused by careless picking, in which the twigs are broken. By others it is said to result from the planting of seeds taken from young plants. The only remedy is to remove and burn the diseased portions. The second disease, if such it can be called, is the ravages of a caterpillar called "*ulo*," which makes its appearance in December, and destroys the crop so quickly that it admits of no remedy.

The method of picking and drying the coca has been so often and so well described of late that it is not necessary to dwell upon it. Coca-picking is a profession to which the children are trained from a tender age. The leaves are picked singly, both hands being employed with a rapid alternating motion,

which strips a twig in an instant. Great care is taken to avoid breaking the twigs, and the young leaves are not picked. Little sacks are tied about the waist, or the women's aprons are pinned or sewn into the required form. They are then transferred to larger sacks, which must be filled and emptied with great promptness, or the leaves will become heated and turn black.

The price here paid for picking is a Bolivian dollar, equal to about seventy-one cents United States currency, for each thirty pounds, which, when dry, will weigh about twelve pounds.

The leaves are exposed to a hot sun upon a pavement of nicely-fitted flat stones, and stirred occasionally until dry. Under the most favorable conditions the drying is accomplished in about three hours. About the coca place are built the storage- and packing-sheds. These are furnished with very broad doors, and men are in constant attendance to sweep the coca with brush-brooms through these broad portals at the slightest indication of rain. A very few drops of rain are sufficient to decolorize and ruin the sale of the coca, though it is my impression that such decolorization, if produced by but little rain, is no indication of loss of cocaine. During the first few days that the dry coca lies within the storage-sheds it undergoes a slight sweating process.

When I come now to speak of the best methods of packing the coca for export, it is fair to say that nothing definite is known. Such coca as has reached Europe or the United States in good condition has done so purely by accident; for perhaps the very next lot, dried, packed, and shipped as nearly as possible in the same manner, has arrived entirely ruined. I have tried many methods, and as often as I had thought that the secret was discovered my hopes have resulted in disappointment.

As regards the exportation of the culture of coca, the experiment has been tried, I believe, but once. Several years since, Mr. F. L. Steinart, of La Paz, shipped a small quantity of seeds *via* London to Ceylon, and during the past season the first products were shipped to London and sold at a high price. Seeds for export should be exposed for several days to a hot sun, so as to rapidly dry the fleshy exterior, which thus forms a protection to the germ within.

It is my opinion that the coca-plant is adapted for culture in many countries where it is now unknown. Among the countries where it would be well to experiment with it

are Guatemala, Mexico, the East and West Indies, India, Southern China, portions of Africa, and possibly of Italy. It is doubtful if it would grow in any portion of the United States. Requiring an average temperature of at least 70°, the only districts at all suited would be Florida and Southern Texas; and it is highly probable that proximity to the sea-coast at so low an altitude would prove fatal. Nor would irrigation prove adequate in those countries possessing a long dry season. The plants must not only have an abundant supply of water at the roots; they must be bathed in a humid atmosphere for the greater portion of the year. But from what I have read of some of the countries above named, I am confident that the plant would there find a congenial home. Jamaica offers especially hopeful conditions.

#### NOTES ON THE USE OF A FIVE PER CENT. SOLUTION OF BRUCINE.

BY RALF W. ZEISS, M.D., PHILADELPHIA.

I HAVE arrived at the following conclusions from experiments made with the brucine kindly handed to me by Dr. Mays:

1. I have twice applied the solution, by means of a tuft of cotton on a cotton-holder, to painful *furuncles* of the external auditory canal. In both cases marked relief was noticed in from two to four minutes, which lasted for some hours, when the pain slowly returned as before. Skin in these cases not broken.

2. In cases of painful *suppurative otitis* of the middle ear (some five or six in all) the solution gave *some* relief in *all* cases; very *marked* relief from pain, lasting for a number of hours, in two cases. In these patients the solution was passed on the cotton tuft down to the fundus of the canal, and the raw and often bleeding surface carefully and thoroughly mopped.

3. I have used the brucine solution some scores of times in *sensitive conditions* of the auditory canal to render the use of instruments painless. No record was kept of these, but in about one-half the cases the patients volunteered the statement, "It don't hurt as much now," while in the other half no results of any importance were obtained, sensitiveness being in no way lessened.

4. Brucine, in my hands, has proved most useful in lessening or entirely abolishing the pain and burning caused by *applications* of

iodine, nitrate of silver, sulphate of copper, and the like to the mucous membrane of the throat and nasal passages. I have repeatedly used it in these cases, perhaps nearly fifty times, and in almost every case relief was noticed, and in the majority of the cases pain and irritation were at once overcome.

5. In one or two cases of *burns* the solution has proved valueless.

6. Painted along the line of incision before opening a shallow abscess, it did no good whatever, the patient suffering as much as usual.

7. Used on the external surface of the body, the five per cent. solution has proved of no value whatever in my hands.

Speaking generally, I do not consider the brucine salt equal in its local effects to the muriate of cocaine. Though more lasting, it is much less reliable, nor does it seem to be so readily absorbed.

In some two or three instances, after liberal applications of brucine to the nasal cavities, patients have complained of having felt wildly "nervous" for some hours afterwards, evidently from the strychnine-like effects of the drug. In no other instances were the slightest toxic effects noted, although as much as  $\frac{1}{2}$  v of the solution has been repeatedly used in the middle ear and nasal fossæ.

1338 SPRING GARDEN STREET.

#### ON ANTIPYRETICS.

BY GEO. J. ZIEGLER, M.D., PHILADELPHIA.

THE editorial on antipyresis in the October number of the THERAPEUTIC GAZETTE justly commends the value of the hydrotherapeutic treatment of fevers, with its general salutary effects in reducing bodily temperature and febrile disorder, subverting concomitant abnormal action, and in restoring the normal processes of the vital economy. But, while this hydiatic treatment of fevers is undoubtedly very beneficial, it is generally so inconvenient and troublesome, especially in the form of baths, even in hospitals, where every appliance therefor is at hand, as to greatly restrict its application, and so much the more in the limited resources of individual life and private practice as often to render its regular and frequent employment therein almost impossible, except in children, and by the moderate local application of ice and cold water externally, and the more or less free use thereof internally. Besides, this hydro-

therapeutics influences secondary rather than primary abnormalities, as it affects the latter only indirectly instead of directly, thereby treating sequents instead of antecedents, or effects rather than causes, whereas some more immediate therapeutic agency is required to counteract or neutralize and resolve the basic abnormality, and subvert the febrile and other morbid sequelæ *ab initio*. Hence the necessity for some more direct, convenient, and effective antipyretic and febrifuge that will suppress the primal aberration and hyperpyrexia *ab origo*, and act in general as a substitute therefor, as well as adjuvant to the hydiatic measures when they are desirable and circumstances are favorable for their employment. Now, in the eager search for new remedies, a large class of powerful antipyretics and febrifuges are strangely overlooked and greatly neglected. These are embodied in those varied sanative and medicinal agents known under the general term of "acids,"—mineral, vegetal, and animal,—most of which are more or less endowed with refrigerant and antifebrile properties, and many with additional specific germicidal, antizymotic, antiseptic, disinfectant, secernent, depurative, and other sanative attributes that render them specially effective in preventing and counteracting pyrexial diseases of the most malignant and destructive, as well as ordinary character, with minor affections of various kinds. Furthermore, besides their general antipyretic and febrifuge power, they differ materially from one another in having some special property adapting them respectively more particularly for the varied states and conditions or individual peculiarities of different diseases, so that by a due appreciation and judicious selection thereof they can severally be more specifically applied to the treatment of the particular form and phase of morbidity to which they are most antagonistic.

Thus, for instance, hydrocyanic acid is a potent, prompt, and persistent antipyretic and febrifuge, speedily allaying irritation, fever, and heat, and causing chilliness and depression. It rapidly reduces excitement of the brain, nervous and muscular, or sensori- and excitomotor system, heart and circulation, with cell, molecular, and vital activity in general, and is especially useful in cerebral, nervous, muscular, and cardiac superexcitability, with hyperæsthesia, irritations, inflammations, fevers, and other disorders of a sthenic type, both general and local. It is, in fact, a powerful and prompt cerebral, nervous, arterial, muscular, molecular, and systemic sedative, but from its

potency must always be exhibited with much care and discretion in small and not too frequent doses, properly diluted, or in the form of cherry-laurel water (aq. lauro-cerasi). As its effects are decided and prolonged, it is better to give small and rather frequent than risk the danger of large doses. Thus, of the dilute acid, beginning with 1 or 2 drops, further diluted; and of the cherry-laurel water, which is liable to vary in strength, from 10 minims to  $\frac{1}{2}$  fluidrachm, carefully graduating the quantity and frequency of the dose to the necessities of the case, diminishing or omitting altogether as the desired effect is produced.

Hydrobromic acid is another active sedative antipyretic and febrifuge of similar general applications, but less energetic and depressing than hydrocyanic acid, having besides valuable antizymotic, antiseptic, disinfectant, depurant, and other properties that render it particularly applicable to the treatment of the sthenic forms and stages of zymotic, septic, and nervous fevers, as of variola, scarlatina, and allied malignant and contagious, with irritative, hectic, and other non-infectious diseases.

Thus, in general, these with other sedative acids are more especially indicated in the acute and sthenic than the asthenic types and phases of disease, and may usually be advantageously exhibited, properly differentiated, singly or in conjunction with other compatible remedies, in neuro-sthenic, pyrexial, and inflammatory disorders.

But, as many febrile and allied diseases are essentially asthenic from the beginning, or inherently of an adynamic nature, antipyretics, febrifuges, nervines, and other remedies of a tonic and supporting character are required therein from their inception. Fortunately, there are various acidulous refrigerants and corroborants of this nature, prominent among which are nitric, hydrochloric, nitro-hydrochloric, sulphuric, phosphoric, lactic, citric, and other acids, with their correlative substances, both medicinal and alimentary, a detail of the special properties and applications of which would be too extensive for the limited space of a journal, but which, with collateral, remedial, and sanative agents, I have presented in my work on the "Basic Pathology and Specific Treatment of Diphtheria, Typhoid, Zymotic, Septic, and Allied Diseases." In addition to their positive antipyretic and febrifuge powers, most of these acidulous medicaments are endowed with valuable germicidal, antizymotic, antiseptic,

antiperiodic, disinfectant, depurant corroborant, and other active remedial properties; and some of them in various alimentary combinations possess additional nutrient attributes, which render them doubly useful for medicinal and dietetic purposes, and in the preventive as well as curative treatment of febrile and other diseases. They not only reduce the bodily heat and fever, but also counteract the basic and underlying abnormality upon which they are dependent, and, at the same time, some supply a modicum of nourishment, while most of them actively promote digestion and nutrition, circulation, secretion, diuresis, depuration, defecation, and renovation; and some general invigoration and tonicity of body and mind.

Thus correct differentiation and discrimination of the specific differences and applications of these varied, simple, and compound acidulous antipyretics, febrifuges, antizymotics, antiseptics, antiperiodics, germicides, disinfectants, sedatives, stimulants, tonics, and nutrients would greatly diminish the occurrence and activity, as well as simplify and render more positive and successful the curative treatment of those formidable febrile and other maladies that so largely afflict and destroy mankind. Besides, they have in general the desirable advantages of being convenient, cheap, and agreeable, or not unpleasant to take, as well as efficient, points often of vital importance to both physicians and patients.

#### THE INTERNAL USE OF CHLOROFORM.

BY DAVIDSON SCOTT, M.D., SPOKANE FALLS, WASHINGTON TERRITORY.

THE fear expressed in some quarters regarding the danger of chloroform internally in physiological doses is entirely unfounded. Chloroform in drachm doses is a prompt and safe hypnotic. The physiological effect is sleep, lasting usually about two hours. To get this effect the same precautions are necessary that obtain in procuring natural sleep, viz., the recumbent posture, a darkened chamber, and quietude. Otherwise the subject experiences an unpleasant effect of stimulation, and notably a sense of fulness in the head, with confusion of thought. These unpleasant effects soon pass off, leaving, perhaps, a slight headache.

In the majority of cases the effects of drachm doses are no more unpleasant than those following a glass of spirits in those not

addicted to its use. In 1867 I reported in *The Chicago Med. Examiner* fifty-six cases of intermittent fever in which I had administered chloroform in drachm doses during the cold stage. A summary of this report may be found in the *American Journal of the Medical Sciences*, April, 1868. Since then I have given it to more than five hundred different individuals for different morbid conditions, without unpleasant effects in any case. It is indicated in congestion from any cause, convulsions due to irritation of the end organs, concussion of the brain, delirium tremens, poisoning by strychnine, etc. It is contraindicated in all inflammatory conditions, and should never be administered when nausea or vomiting is present, although no danger will result, but the fumes being regurgitated through the mouth and nostrils, is alarming to timid patients. In the chills designated *congestive* it is *specific*, but may have to be repeated in twenty minutes to half an hour, never oftener in my experience. Infantile convulsions, due to peripheral irritation, it arrests promptly. Many who read these lines will be surprised at the statement that I have frequently administered undiluted chloroform in teaspoonful doses to infants of two and three years of age during the unconsciousness that follows convulsions, sometimes prying the mouth open, or letting it filter through the teeth. When it gathers in the pharynx it promptly produces reflex action, and is invariably swallowed, producing a profound sleep, from which the little patient always awoke without an untoward symptom, and in no instance did it ever fail to arrest the convulsion. Of late years, however, I use nitrite of amyl preferably in such cases.

The following case, which was reported in connection with the administration of chloroform internally in *The Chicago Med. Examiner*, March, 1869, will illustrate the subject perhaps better than anything I might say. In the summer of 1868 I was hastily summoned to the bedside of a lady whom some hours—twelve, I think—previously I had delivered of a child by podalic version, the case having been one of placenta prævia, and found her just emerging from a convulsion,—the twelfth. She was cold, pulseless, bloody foam issuing from the mouth, with very feeble stertorous respiration. Upon the bureau, near the head of the bed, there happened to lay a tablespoon, and having a vial of chloroform in my pocket, I immediately filled this large spoon *full*, and, prying open the set jaws, poured the whole into the mouth.

It was immediately swallowed, and almost momentarily after the face flushed, the pulse came up full and bounding, the respiration changed to that of natural sleep, and after two hours' peaceful sleep she awoke with some confusion of thought, but nothing worse, and made a rapid and good recovery. This was the largest amount I ever gave at a single dose.

The following case is anomalous. I give it as a physiological—perhaps I should say pathological—curio. John D., an inebriate, addicted to alcohol when it could be had, but would consume laudanum in ounce libations procured from the apothecary when the barkeepers refused him drink or John's friends failed to "set 'em up." One evening he applied for treatment; he was just on the borderland of delirium tremens. It was at a period when I was experimenting with chloroform. Acting on the premise that less than one fluidounce had never proved fatal, I directed that a teaspoonful should be given in a glass of sweetened water every half-hour till sleep ensued, giving, if necessary, seven doses. If this failed to procure sleep I was to be informed. Next morning I saw John bright and early at work painting a house, that being his trade. Now it so happened that I had confided to the attendant of the night before a four-ounce bottle filled with chloroform. Late that evening John appeared at my office with, "Doctor, I would like this bottle refilled." Greatly surprised, it being the chloroform-bottle, I asked him what he had done with the contents. He replied that he had taken a swallow from the bottle as the occasion demanded during the day, and he regarded it as the "finest treatment" he had ever had. Now, the facts are, this fellow had been given six teaspoonfuls the night before, when falling asleep, the attendant retired, leaving the bottle on the mantel, where it was found by the patient in the morning, with the result as stated. He actually swallowed fully twenty-five fluidrachms of undiluted chloroform within a period of twelve hours, performing a large day's work with more intelligence than he usually manifested, and ate three hearty meals, as I learned from his employer.

To the late Dr. A. P. Merrill, of New York, formerly Professor of Practice in the Memphis Medical College, at Memphis, Tenn., is due the discovery of the power of chloroform in drachm doses over chill and congestion. I think there is little doubt that he was the first to administer this large amount for any pur-

pose. My object in writing this communication is due to the fact that chloroform has become so popular as a tænicide, and the idea of giving it in such small doses as I see reported is absurd to me with the experience I have had with the remedy. I first used chloroform for tapeworm in 1869. It suggested itself to my mind after reading a case reported as being successfully treated by sulphuric ether. Theoretically the remedy is plausible. Without doubt chloroform is rapidly vaporized on reaching the stomach, and diffuses itself along the intestinal canal. In my hands it has not proved a brilliant success in these cases. However, the following plan will be found best if it be decided to give it a trial: Let the patient take a fluidrachm, well mixed in a half-tumbler of sweetened water, before rising in the morning, and followed immediately by a brisk purge. Now let the room be darkened and quietude prevail; he will fall into a pleasant and natural slumber, from which he will awaken in one to two hours refreshed, perhaps not until admonished that his physic is ready to operate. As the remedy is harmless, and not unpleasant, it may be repeated as often as desired.

#### THE TREATMENT OF VARICOSE VEINS.

By J. M. BUZZEL, M.D.

I NOTICED in the GAZETTE of November 16 an abstract of an article published in the *British Medical Journal*, by Dr. J. F. Frye, advocating the removal of a section of the varicose vein in varix of the leg.

I believe that I have found a "more excellent way" of treating this very troublesome disease, and I feel disposed to furnish a brief account of the method of operation and treatment which I have practised for forty-eight years in varix of the leg, and the results of the same.

Up to the time of my graduation but little had been done in the treatment of this disease, except to palliate the sufferings of the unfortunate patient by the elastic stocking or bandage and make an effort to heal up the ulcers which usually accompany this affection of the veins. The surgeon was not able from anything he had read or heard to hold out any promise of a cure of this disease.

Attempts for the occlusion, or rather the obliteration, of the diseased veins were made by pins and caustic, because something must be done to pacify the patient and make

him reconciled to his lot. In view of this dubious state of surgical science upon this subject, I was led to inquire what was the objective-point to be reached in curing this diseased state of the veins. My conclusion was that the old veins that had, by degrees, in consequence of the thinness of their coats, become greatly dilated and overdistended with blood, the circulation in them growing slower as they grew larger, producing heat and discomfort in the limb, must be exchanged for new ones, the blood in the mean time being returned in the deep-seated veins.

The next question, of course, to be settled was, how was this important metamorphosis to be accomplished? The answer to me was plain. If the occlusion or obliteration of a small section of the veins, as had been the object of those who had inserted pins, ligatures, or made caustic sores, had measurably improved, temporarily, the condition of things,—if a little *occlusion* was good, a complete occlusion must be better, if it could be safely accomplished. And the entire arrest of the circulation in the internal saphenic vein, closing all of its tributary branches below the knee at once, seemed to me to be the way to accomplish this most desirable purpose.

Having heard the venerable surgeon, Prof. R. D. Mussey, M.D., in one of his lectures upon this subject, say that, in his opinion, the operation of ligating the saphenic vein was a feasible one, I was determined the first opportunity I should have to make a trial of its operation. And it was not long after I commenced practice before a very interesting case of varix presented for my treatment.

A Mr. J. M., of Standish, Me., about 45 years old, had been greatly afflicted with varix of the *left* leg, which is the one most commonly affected where only one limb is involved, and upon which there was a large indolent ulcer, as large as the hand, having existed there several years.

I stated to the patient my plan for the cure of such cases. M. was ready to trust his life in my hands. I performed the operation, which I had carefully planned, and which I will soon describe. I placed the patient in a proper position, covered the ulcer upon the leg with simple diachylon plaster, bandaged the limb, and kept the patient confined to his bed about three weeks; when, upon removing the bandage, the aspect of the limb was as natural as the other, the ulcer having healed entirely, and the new and perfect veins showed themselves when the foot was put upon the floor, the old veins being entirely obliterated.

By the use of an elastic stocking, which I always recommend, to prevent the new veins from becoming distended and tortuous like the old ones, he lived some twenty-five years with no return of the disease.

Although I have had several cases with favorable results, I will refer to but one other case, which was, I may say, a bad one.

R. V., an elder in the family of Shakers, at Lebanon, N. Y., about 40 years of age, came to me with varix of the left leg. The veins were extremely large, the saphenic vein, from the knee upward to its emergence into the groin, being as large as a broom-stick.

I stated to the patient what I had done, then several times, and the results. He submitted to the operation and treatment, although warned by a surgeon in a college in the State that it would "kill him." But he lived through the operation, had a new set of veins, and, by the proper support of the leg, he has had no return of the disease. I had a letter from him eight years after the operation, and he reported that he had no varicose veins upon his leg.

I will now, as briefly as I can and make myself understood, describe the operation and treatment. If there are unhealthy *ulcers* upon the affected limb, I endeavor to improve their condition so as to show a healthy state of granulation. I then wash the limb with some antiseptic mixture, latterly the carbolic solution, and apply over the ulcer a diachylon plaster. The next step of the operation is, by the aid of the right thumb and forefinger of an assistant, and of my left, to pinch up the integument directly over the saphenous vein upon the inside of the knee, where it is easily found, and passing a bistoury through the two folds of integument, with the back of the bistoury towards the vein, cutting from within outwards, I make an incision about three-quarters of an inch in length, which will bring the vein plainly into view. I then pass a ligature beneath the vein, taking care not to include the nerve that accompanies the vein, but do not tie the vein in this stage of the proceedings. I then raise the foot as high as convenient and commence the application of a bandage, which I apply closely upon the limb from the toes up to the knee, forcing the return of the blood in the veins as much as possible, with the hands in advance of the bandage. When the bandage has reached the knee, I tie the vein, not so tight as to divide its coats, but simply to arrest the upward movement of the blood in the vein, leaving one branch of the ligature out, and the wound is dressed with

plaster. I then keep the foot and leg raised as high as comfortable to the patient, and keep the whole limb wet with cold water with the carbolic acid solution, with the occasional use of the tincture of arnica or lobelia, and paying particular attention to the state of the wound, which to the feel is somewhat tender and slightly inflamed. After the ligature becomes loosened, I cut one branch and remove it, as there is no longer any need of it.

In every case I have had the patient has been comfortable throughout his confinement, having no fever, swelling, or pain. I have given internally, after a few days, aconite, Seidlitz powders, etc., to *prevent* inflammation, fever, etc.

#### PILOCARPINE IN TOOTHACHE.

MR. A. P. KURZAKOFF, according to the *Medical Press*, November 4, 1885, states that hypodermic injections of pilocarpine will relieve toothache. A solution of 2 grains of the salt in  $\frac{1}{2}$  ounce of distilled water was used, the injection being made into the temporal region on the side of the odontalgia. In two of the cases one-eighth, and in a third case one-quarter, of a grain of the salt was injected. In all the cases pain disappeared permanently in about an hour after the injection; about the same time salivation and perspiration (caused by the drug) also ceased. In one of the cases, in that of a man, *æt.* 46, with rheumatic periodontitis associated with agonizing earache, the injections (of a quarter of a grain) produced profuse vomiting, with cyanosis, general weakness, and drowsiness, all of which symptoms disappeared in about an hour and a half after taking 20 drops of tincture of valerian. The author thinks that this simple plan of treatment fully deserves a further and more extensive trial.

#### THE INCOMPATIBILITY OF ANTIPYRIN.

DR. ECCLES states in the *New York Medical Journal*, October 24, 1885, that he has found that sweet spirits of nitre is incompatible with antipyrin. When he has used antipyrin added to sweet spirits of nitre, the mixture at first is clear and colorless, but becomes green with some hours' standing. Since antipyrin is a coal-tar product, Dr. Eccles believes that the change of color is due to the formation of a green aniline. This incompatibility is worth remembering, since both antipyrin and sweet spirits of nitre are antipyretics, and might be prescribed together.

# The Therapeutic Gazette

EDITED BY  
HORATIO C. WOOD, M.D.,  
AND  
ROBERT MEADE SMITH, M.D.,  
PHILADELPHIA.

DETROIT, MICH., Jan. 15, 1886.

Foreign subscriptions may be ordered through our agent in England, Mr. H. K. Lewis, Medical Publisher and Bookseller, 136 Gower street, London. Price 10s. Remittances may be made either by Postal Order or Stamps.

Price to Foreign Subscribers direct (postage included) \$4.50 (10 shillings). English postage stamps received on remittances.

Editorial communications should be addressed 1025 Chestnut Street, Philadelphia. Business communications should be addressed to the publisher.

## Leading Articles.

### TE SALUTAMUS.

AS this is the first birthday of the THERAPEUTIC GAZETTE since its adoption into the family of its present parentage, it is but right that we should sincerely thank the profession for the support which has been given to us, and acknowledge with humility the many congratulations which we have received concerning the growth of our adopted child.

If permission be granted we would also like to philosophize a little, and to say a few things to our contributors and to our readers concerning the spirit which should possess all of us as therapeutists. Our art of healing is at present far from complete, although the record of the past twenty years is one of which we may well speak with pride. Old remedies have been found to possess new features; new remedies of value have been added to our lists; great generalizations have been determined; knowledge has been perfected in detail; previously unknown territories have been more or less explored; and at the same time

a therapeutic momentum has been acquired which must carry forward the profession upon this line of progress with ever accelerating rapidity. Wherever, however, there is in nature excessive vitality and vigor, there is always a tendency to irregular development, to the formation of all kinds of straggling growths, to the production of weeds, and to general rankness. So, it seems to us, it is in therapeutics. We acknowledge that in the present more than at any past time new remedies of no value or of little value are being praised without number and beyond measure, but we recognize in such outrunnings the presence of an excess of vitality. This explanation may be satisfactory to our pride, but the facts remain, and as editors of the leading therapeutic journal of the world we feel that, if ever the hoe and the pruning-knife of criticism were needed in pharmacology, it is at the present moment. Most earnestly would we call the attention of writers of general treatises on therapeutics to the great importance of their not dogmatically asserting as true that which is unproven. The effort should be unceasing to weigh evidence with the greatest care, and there should be an ever present fear of sacrificing truth to an appearance of perfection. Better always is it to leave the therapeutic edifice jagged, uncouth, and unfinished than to put up a superstructure which the first storm shall cast down, and whose ruin shall involve the good with the bad.

The therapeutic observer and the writer of individual papers also at present seem to us to need a caution. Brilliant theories, important discoveries of apparent facts so rapidly attract attention and are so easily made, whilst close observation and permanent results require so much toil and are so often barren in immediate glory, that the temptation to give reins to the imagination comes almost as strongly to the modern physician as did the carnal visions to St. Anthony; but as did St. Anthony, so ought we also to resist even to the death.

The spirit which should rule the minds of all therapeutic co-workers is that of scepticism. Let us believe nothing until it is proven. It can do no harm to wait a little until an alleged fact or a plausible theory is established; but great injury may result from an untrue allegation or a false theory gaining foothold and rooting itself, so that its influence shall continue for years. Possibly scores of children, certainly many lives, have been sacrificed in the last ten or fifteen years to the

theory that the chlorate of potassium yields its oxygen in the blood, and thereby purifies the vital fluid. A theory as baseless as it is ingenious and attractive, but which still has its advocates, and which within a few weeks we saw taught by a learned professor to a gaping crowd of students,—a theory which led in practice to the immoderate use of the chlorate in diphtheria, and no doubt to a notable increase in the death-roll.

Another theory almost as universally believed in and almost as groundless as the one just spoken of is that which attributes the effects of the bromide of potassium upon the nervous system to contraction of the finer blood-vessels, and the consequent production of cerebral and spinal anæmia. How many pages have been written in regard to this theory! What great discourses and imaginings concerning the nature of epilepsy and various other diseases have been built upon it! How it still permeates neurological writings! and yet there never has been a single well-observed fact supporting it. Evolved out of the inner consciousness of the neurological clinician, it has been swallowed by a profession whose gullibility is still marvellous and triumphant.

Some seventeen hundred years ago Galen wrote at the end of his great treatise,—*περι χρειας των εν ανθρωπου σωματι μοριων*,—that his anatomical facts and studies were so many hymns sung before the gods.

What discords of false notes! what pæans of unbridled imagination have these our therapeutic hymns contained! Let us strive that in the future our songs shall be as redolent of cleanly-winnowed truth as they have in the past been heavy with the dust of falsehood.

The scepticism the therapist ought to encourage is not one as to the value of drugs in the treatment of disease. It is as to the assertions made concerning new drugs, and as to theories which are brought forward to explain the action of old and new drugs. The editors of the THERAPEUTIC GAZETTE can perhaps best express their appreciation of drugs by an anecdote concerning the late Dr. George B. Wood. This eminent therapist was accustomed to say that when any physician came to him and professed lack of faith in the efficacy of medicines, he always replied that this lack of faith must rest upon the physician not having used drugs properly, because the results to be achieved by the proper use of remedial measures are so apparent that they can be seen at once.

#### CHLOROFORM BY THE MOUTH.

**B**OTH to the toxicologist and therapist the local as well as the constitutional effects of chloroform when given by the mouth are of interest. There can be but little doubt that much of the curative influence of the drug when so administered is the result of the peculiar irritation which it produces in the gastro-intestinal tract; and it is hardly conceivable that in cases of exhaustion or of failure of the circulation the sudden arousing sometimes produced by draughts of chloroform are caused by any direct general or constitutional action. Careful experimentation upon the lower animals, made by various observers, shows that any influence this drug after absorption exerts upon the circulation is one of depression. Under its influence the arterial pressure falls steadily; at no time during the action of the drug is the arterial force increased unless the respiration be affected. Any one who has stimulated a sensitive nerve in an animal whose artery is connected with the manometer must recognize the enormous influence which such stimulation has upon the blood-pressure. The gastro-intestinal tract of man offers an enormous surface upon which are outspread everywhere afferent nerves, and any severe irritation of this surface must have an immediate effect. When the woman who is suffering from faintness has ammonia held to her nostrils the irritating vapors bring about reaction by their influence upon the nerves in the nasal mucous membrane. That the rousing of the circulation is under these circumstances not the result of any absorption of ammonia, and consequent direct stimulation of the heart, is shown by the minute quantity of the ammonia necessary and the rapidity of the effect.

The immediate flushing of the face which is produced in some people by small doses of alcohol is also not the result of a constitutional action of the drug, but of the irritation of the gastric mucous membrane which it causes. This has been frequently verified by the writer in a case which has long been under his care. In this patient two or three teaspoonfuls of wine will produce almost instantaneously a facial coloration which might put to blush that of a boiled lobster. If the wine be freely diluted this congestion of the face does not occur; and if vinegar be taken instead of wine the effect upon the face is precisely as though alcohol had been ingested. Certainly acetic acid, taken in the form of one or two teaspoonfuls of vinegar, has no instan-

taneous direct effect upon the heart or blood-vessels.

The local effects of chloroform are far more severe than are those of alcohol, and it is hardly open to doubt that it is these local effects which produce sudden awakening from a faint. The severity of these effects is revealed by the severe gastritis which almost universally follows poisoning by chloroform given by the mouth; whilst the jaundice which in many of these cases accompanies the gastritis shows that the chloroform penetrates everywhere through the abdominal viscera. In a few cases death has resulted after a lapse of as much as eight days from this secondary gastritis (see *New York Med. Record*, July 11, 1885). After death from chloroform taken by the mouth anatomical evidences of gastro-intestinal inflammation have been very pronounced.

The amount of chloroform that is required to kill when swallowed varies very greatly. Evidently this is in part due to the variability in the rate and completeness of absorption of the drug through the gastro-intestinal mucous membrane. Taylor describes a case in which recovery occurred after ingestion of four ounces; but according to L. Lewin a single drachm has produced death. In our opinion under no circumstances is the practitioner justified in giving by the stomach more than half a drachm at a single dose. The drug meets no indication which cannot be equally well or better met by the less dangerous remedies, and we cannot see that a practitioner is justified in taking the risks. Indeed, we doubt whether chloroform ought to be used at all internally, excepting as a local remedy in cases of gastric or intestinal neuralgia or spasm, or other similar affection. In cases of colic, with or without diarrhoea, and in cases of sudden nervous diarrhoea from intestinal relaxation, it is invaluable; but under these circumstances the dose should not exceed 25 drops, to be repeated *pro re nata*.

#### ACCIDENTS WITH HYPODERMIC MEDICATION: HYOSCINE, MORPHINE, ELATERIUM.

THE numerous reports which have been made upon the use of hydrobromate of hyoscine seemed to have settled that it is a drug of very great value, whose especial application is in cases of sleeplessness, combined with great excitement of the cerebral cortex. As yet no case of poisoning has been re-

corded, but it may be remembered by some of our readers that Dr. Wood, in one of his articles, called attention to the fact that in two cases he had seen evidences of paralysis of the laryngeal nerves, with consequent symptoms of sudden suffocation, under its use. In a recent case which occurred in the practice of Dr. M. O'Hara, of Philadelphia,  $\frac{1}{8}$  of a grain administered hypodermically is said to have produced very serious consequences. There was no sleep or dilated pupils, but paralysis of the pharynx, suffusion of the face, loss of power of articulation, fever, with great muscular relaxation, and partial loss of co-ordinating power, lasting for twenty-eight hours. After recovery there was a total lack of remembrance of occurrences which took place during the seven hours following the taking of the medicine.

In the administration of minute doses of medicine the doctor is so entirely at the mercy of the apothecary, and it is so difficult, without expensive chemical analysis, to prove that the solution used had the strength ordered, that there is always a suspicion in cases like the present that more of the alkaloid was injected than was intended. The mere assertions of the druggist must count for nothing, as if he had made a mistake he would probably not be aware of it, and even were he aware of the blunder, to convert knowledge into acknowledgment would hopelessly strain ordinary human nature. It is possible, however, that there may be individuals whose idiosyncrasies are such as to render them highly susceptible to the action of this drug, and that the symptoms were caused by the  $\frac{1}{8}$  of a grain. We once injected hypodermically  $\frac{1}{4}$  (according to the prescription) of a grain of morphine into the arm of a patient, who fell back, apparently dead, inside of one minute after the time that the piston of the syringe was thrust downward, and who was only saved by long and most assiduous treatment. We have always believed that in this case the drug was thrown directly into a vein, and carried in a concentrated condition to the heart and nerve-centres. The hypodermic administration of remedies is liable to dangers which can only be partially provided against.

We have had detailed to us, by a physician in the United States, a case which occurred in his own practice, which seems worthy of being here noted. For obvious reasons the name of the physician is omitted, but there can be no doubt of the authenticity of the statements. In order to produce vomiting

and purging in a case of severe narcotic poisoning, elaterium was used hypodermically. The injection was followed in the course of a few minutes by free emesis and purging and very severe local irritation, ending in abscess. A few days later the patient was attacked with tetanus, which ran a rapid course to a fatal termination.

In connection with hypodermic injections may be mentioned the necessity, not always appreciated, of keeping the needle absolutely clean. This applies with more force to hospital than to private practice. We have seen patients to whom we were giving daily hypodermic injections without any local trouble, who then went into the hospital, and on a continuance of the treatment suffered from a series of abscesses. These abscesses were attributed by the hospital authorities to the bad state of the constitution, but were really due to septic poisoning from a dirty needle. The hypodermic needle in every hospital should be habitually kept in a strong carbolized oil.

In order to avoid throwing the medicine directly into a vein, the point of the needle should be withdrawn a little after being plunged deeply into the tissue. Do what we may, however, a certain amount of danger accompanies the hypodermic injection. A risk which is not sufficient to interfere with our using the method when there is any distinct call for its employment, but which is too great to warrant that perpetual employment of the syringe that is practised by some physicians.

#### HYPNONE, THE LATEST HYPNOTIC.

THE readers of the GAZETTE, who by this time take it for granted that nearly each month presents to the medical world a new antipyretic, anæsthetic, or at least hypnotic, will not be disappointed even by the issue of this number of the GAZETTE. "Hypnone" is the auspicious label of the long-looked-for ideal hypnotic. Dujardin-Beaumetz presented to the Academy of Medicine on the 10th of November his first results of a series of observations made with phenyl-methylacetone, to which drug he gave the name of "hypnone." Popoff, of Warsaw, had previously examined hypnone as to its chemical properties, and ascertained that it was decomposed in the organism into carbonic and benzoic acid, and that it appeared in the urine as a hippurate. Dujardin-Beaumetz found that the drug produced a deep physiological sleep in adults when exhibited in doses ranging from  $\frac{3}{4}$  to 2

drops; he gave it mixed with some glycerin in gelatin-capsules. In alcoholic subjects it acted decidedly better than either paraldehyde or hydrate of chloral. Altogether the drug was tried in nine cases and produced no undesirable secondary symptoms, nor could any intolerance be observed; the breath simply was noted to be unpleasant when the drug evaporated from the pneumonic surfaces. In guinea-pigs subcutaneous injections of  $7\frac{1}{2}$  to 15 drops produced a remarkably profound and stupor-like sleep, which gradually assumed a comatose nature, in which, after five to six hours, the animal perished. Dujardin-Beaumetz regards hypnone as a powerful, pure hypnotic, and anticipates the best of success with the new drug.

According to the *Gaz. Hebdomadaire* of November 20, 1885, Dujardin-Beaumetz again emphasized in the Academy the fact that hypnone will act promptly in cases of insomnia depending upon cerebral hyperexcitation, but will prove wholly useless in insomnia caused by pain. A clear and specific indication of this nature is of course much more apt to win confidence than the *à tout cas* eulogies of new remedies to which we have been of late accustomed, especially from German quarters. The claim that hypnone is actually well borne by the stomach would, if found to be a just one, of course materially enhance the value of the drug, as the principal objection to all ordinarily-employed hypnotics is less a want of activity than their ill effects on the digestive tract.

The drug itself is by no means a discovery of a very recent period, as Friedel had extracted it already in 1857 from the products of distillation of benzoate and acetate of calcium. He represented the drug by the formula of  $C_6H_5 - CO - CH_3$ . It crystallizes in large flakes, becomes fusible at  $15^\circ$  (C.), boils at  $98^\circ$  (C.), and has a density of 1.032. Its taste is hot, and its odor resembles that of bitter almonds and oil of wintergreen together.

Four to ten drops taken at once are, according to Dujardin-Beaumetz's statement, sufficient to produce a refreshing and sufficiently long sleep. It is best taken in either of two preparations, as advised by Pierre Vigier, viz., a syrup or elixir. The syrup of hypnone is prepared as follows:

- R Hypnone, gtt. i;  
Alcohol ( $90^\circ$ ),  $\mathfrak{m}_{\text{xvi}}$ ;  
Syr. aurant. flor.,  $\mathfrak{m}_{\text{lxxx}}$ ;  
Syr. lauro-cerasi,  $\mathfrak{m}_{\text{xvi}}$ .

The drop of hypnone is put in the alcohol.

the syrups are then added, and the whole liquid is well stirred. A child would have to take at least double the quantity of the above mixture so as to get 2 or 3 drops, while an adult would require at least four such doses.

The elixir is prepared as follows :

R Hypnone, gtt. i ;  
Alcohol (60°),  
Spir. menth. pip., aa m℥.

To be prepared in the same manner as the syrup.

#### REMARKS ON ALCOHOLISM.

WE hear a good deal in this country of the untoward effects which alcohol in any form is supposed to exert on the human economy, but rarely ever a plea in its favor. That even an habitual use of alcoholics under certain conditions—aside of medicinal alcoholic preparations—may exert a favorable influence on nutrition few therapeutists would venture to deny. To the poor workingmen, who lack the advantages of a proper and regular diet, who, in scanty clothing, are exposed to the various changes of temperature and season, alcohol forms an indisputable nutritive factor of the highest type ; it is, in other words, an irreplaceable and necessary article of diet for the working-classes. The question of excesses and their consequences belongs only partly to the régime of the therapeutist,—viz., as far as the effects of alcoholic excesses on the body are concerned,—while their moral and social sequelæ ought in no way concern the therapeutic investigator.

Lanceraux, of Paris, recently delivered an interesting lecture on the subject before the Parisian Academy, which, as seen in the report of the *Gazette Hebdomadaire* of November 20, 1885, brings this subject into fresh prominence.

Alcohol seems to have a direct power to shorten the duration of human life ; at least Lanceraux, who has studied this subject for about twenty years with great care, has come to this conclusion. "Fifty or sixty years," this author says, "is the highest age ever attained by alcoholists."

In the first place, it would not be an easy matter nowadays to exactly define the word alcoholist. Some of our readers might differ in this respect, and say it is easy enough to define an alcoholist. An alcoholist is a person, they would say, who daily or habitually, at least for a certain protracted and usually continuous period of life, is or has been indulging in such excesses of alcohol as to

have suffered physical and moral losses. A closer investigation, however, will soon convince us that this definition—which, by the way, we actually encountered some time ago in a medical journal—is exceedingly unsatisfactory, nay, actually improper. We venture to say that it would suit four-fifths of all students and teachers of a French or German university. As peculiar as this statement might appear on first sight, any one familiar with the usages of the Continental academic circles will readily confirm it. Hence, we repeat, Lanceraux's expression, "alcoholist," is an exceedingly vague one, and scarcely admits of a strict and satisfactory definition. If, based on statistics, this author assigns to alcoholists no higher duration of life than fifty or sixty, he would find some noteworthy exceptions in our Philadelphia Hospital,—the pauper department,—where we could introduce to him a number of bibulous veterans approaching closely a centenary. Our French author has also evidently forgotten Homer's account of the most venerable of all tipplers, Nestor, who attained an age of treble an ordinary duration. Fifty to sixty years is by no means a bad average ; but, on the contrary, a very acceptable one, and Lanceraux will not be able to frighten many drinkers by such statistical facts. It would be interesting to know how many tubercular subjects, who at the same time indulged in the cup, attained the age of fifty or sixty years. If Lanceraux could count up even a moderate number among his statistical material, it would be a strong indication for every otherwise doomed tubercular person to try alcoholism with the view of prolonging life.

Lanceraux has paid special attention to the comparative physiological results of the various alcoholic beverages, and pronounces some very sensible, though to many Americans occasionally surprising, axioms. "Cider, beer, and even wine, if properly prepared and not adulterated, are in every respect," says our author, "wholesome beverages, the use of which ought to be encouraged." He admits, however, that wine is capable to lead to a man's social ruin, though he does not refer to any possible deleterious effects on the constitution. Here our author makes the interesting statement that the craving for wine is readily transmissible to the progeny. We doubt, however, that this theory, at least in such unqualified a condition, can be accepted. As to the actual commercial spirits, such as brandy, whiskey, rum, gin, etc., Lanceraux asserts that the results of excesses do not limit

themselves to the drinking persons exclusively, but are, as we readily accept, extended to their offspring. The pathological phenomena subsequent to alcoholic excesses are principally alterations of sensibility, of movement, of the vasomotoric and the intellectual functions. In the offspring of alcoholic indulgents it is exceedingly common to find nutritive deficiencies and certain peculiar constitutional conditions which prove a ready predisposition to tuberculosis. Lanceraux concludes his interesting essay by advancing certain pertinent propositions, which might be suitable for France, but would be rather out of place in America. He recommends absolute liberty for the sale of every alcoholic beverage, a strict superintendence of the sold material, repeated official examination of them, an immensely higher duty on all alcoholic spirits, the necessity of a strictly moral character of every vendor, and the distribution of prizes for the preparation of the most wholesome alcoholic beverages.

#### IODOL, A NEW ANTISEPTIC.

IODOL ( $C_6H_4NH$ ) was first produced synthetically in 1883, by Messrs. Ciamician and Dennstedt, by the action of iodine on pyrrol ( $C_4H_7NH$ ) in the presence of caustic potash. Its reaction is slightly acid, and it is free from the penetrating and disagreeable odor of iodoform. It exists in the form of a brown amorphous powder, insoluble in water, slightly soluble in cold alcohol, and readily soluble in warm alcohol, ether, and acetic acid, and in oil. It contains eighty per cent. of iodine. Iodol may be warmed to  $100^\circ C.$  without undergoing decomposition. At higher temperatures iodine vapor is given off, and a carbonaceous mass remains. From its alcoholic solutions it is precipitated by water, but not by glycerin. When warmed with nitric acid, the alcohol solution turns bright red, and in sulphuric acid dissolves with the formation of a green color. Clinical experiments made with this new product are as yet too incomplete to enable us to form any decisive opinion as to its value. According to Dr. Mazzoni, it is an even more powerful antiseptic than iodoform, is entirely free from the odor of iodoform, and has not yet produced any symptoms of poisoning. It appears also to act as a local anæsthetic, and favors granulation. Applied locally to chancroids, iodol produces the same effect as salicylic acid. A one hundredth per cent. solution in oil in-

jected under the skin produces no reaction, while the passage of iodine into the urine has been determined. Administered internally in doses of 2 grains daily, the iodol is said not to produce the slightest trace of intestinal irritation.

#### TREATMENT OF HYSTERIA IN CHILDREN.

ALTHOUGH numerous affections of the infantile phases of life, even those of the nervous system, assume, without therapeutic interference, in the course of time, a very benign type and disappear wholly through nature's own restorative and recuperative power, the physician is nevertheless frequently enabled to exert a direct favorable influence upon the morbid process. The numerous types of nervous hyperexcitation occurring in children, unless a grave hereditary predisposition exists, allow usually of a favorable prognosis, though their frequently observed rebellious nature, and the possible danger of establishing a habit, call for a careful medical treatment. We find in the *Wien. Med. Wochenschrift* of November 14 an instructive paper by Dr. Herz on the treatment of hysteria in children, which is worthy of a brief representation in the GAZETTE. Omitting the author's remarks on the etiology and pathology of the affection, we shall simply review his ideas of treatment.

The first and most important indication in infantile hysteria is the strengthening and rehabilitation of the weakened organism, and especially of the central nervous system, by the various dietetic, hygienic, and medicinal measures. Next in importance stands the tranquillization of the physical and mental excitation, either by direct medication or by appropriate psychical influences. The last factor is often obtained by an apparent disregard of the affection, actual or only threatened removal of the child from its domestic surroundings. There are cases on record in which an actually curative effect was gained by various threats, such as to cut off the hair, burn the spine, or perform an operation. These means have been found to be especially efficient when the hysteria resulted not primarily, but on account of the child's association with other hysterical children.\*

Anæmia and chlorosis, whenever they exist in an hysterical child, as is so often the case,

\* This singular mode of acquiring the hysterical habit has also been observed in the Hospital of the University of Pennsylvania some four-years ago.

of course have to be treated by the well-known measures.

Various authors, especially Jacobi, of New York, have lately called attention to the rôle that masturbation in either sex plays in the etiology of hysteria. It is hence necessary to see that this nefarious practice is checked, if found to exist, and rendered as nearly inexecutable as possible by appropriate means. As various sources of irritation emanating from the genital organs, such as phimosis, the aggregation of smegma under the prepuce, and in girls an elongated clitoris, often lead to masturbation, the genital organs should receive a careful examination and eventual treatment. Painting the vagina twice daily with a ten per cent. solution of cocaine has been found to be an able agency in subduing the hyperirritation of the sexual organs in girls accustomed to practise masturbation.

As to the direct therapeutic treatment of hysteria in children, our author agrees with Henoeh, the acknowledged highest authority on children's diseases, that there is no specific remedy for it. Henoeh prefers the hydrate of chloral to all other medicines, though he regards morphine as almost equally valuable. The former he prescribes in 0.5 to 1.00 doses ( $7\frac{1}{2}$  to 15 grains); the latter, both internally and hypodermically, in 0.005 to 0.01 doses ( $\frac{1}{16}$  to  $\frac{1}{8}$  grain). Inhalations of chloroform, though ordinarily exerting only a transient salutary influence, will be found requisite in the occasional paroxysms involving the laryngeal organs. Arsenic and quinine are highly prized by some practitioners, but they possess likewise no constant value. In view of the so frequently underlying anæmic base, small doses of iron and arsenic, continued systematically for a long period, will invariably be found useful. Warm baths, applied frequently, and lasting fifteen to thirty minutes, fresh air, and nourishing food, are always highly commendable in every case.

As especial sedatives of the overexcited nervous system, the bromides of potassium and ammonia and belladonna have always been held in high repute. A combination of bromide of potassium and chloral hydrate appears to act especially well. It is advisable to give 15 grains of bromide of potassium in the morning and afternoon, and 7 grains of chloral hydrate at night, and to combine later both remedies, as follows:

R Chloral. hydrat., gr. xv;  
Pot. brom., gr. xxx;  
Aq. dest., ℥i. M.

S.—Two teaspoonfuls every two hours.

After continuing this medication for some time, the following combination of arsenic and iron recommends itself:

R Liq. pot. arsenit., gtt. xv;  
Ferri ox. hydr., ℥i. M.  
S.—A teaspoonful twice a day.

Later the iron is suspended and the arsenic retained alone. Politzer, of Vienna, regards the hydrobromate and bihydrobromate of iron as two very valuable preparations in the hysteria of children, and exhibits them in doses of 4 to 7 grains three to four times daily. The same therapist recommends also the tincture of belladonna, 3 drops *pro die*, gradually increasing the dose up to 5 drops, and then gradually decreasing again.

The application of cold baths, and even of electricity, cannot claim to have produced any satisfactory results.

#### TREATMENT OF SYPHILIS BY SULPHUROUS WATERS.

BOTH the profession and the laity are at the present day fully aware of the fact that the drug-store is by no means the only source and medium of alleviating or curing diseases. The high therapeutic value of such agents as air, light, and water, formerly almost wholly overlooked, is being more and more understood and appreciated. Though the numerous medicinal uses of simple water are as highly prized by the American practitioner as by his European colleagues, it seems to us, as we have repeatedly suggested, that the thermal waters have hitherto in this country not received the full attention to which they are entitled. The paper of Dr. Doit (appearing in the *Gaz. des Hôpitaux*, October 24, 1885), treating of the action of sulphurous waters in syphilis, is all the more worthy of our attention as it refers to an affection the therapeutics of which are far from being satisfactory. The following *résumé* comprises the principal conclusions of Doit's paper:

1. The sulphurous waters can, under certain conditions (to be referred to later), aggravate the syphilitic troubles.
2. They must ordinarily, however, be regarded as curative of the affection.
3. They serve to distinguish syphilitic from other affections by their therapeutic results.
4. They expose latent syphilis.
5. They assist in the differential diagnosis of simple and syphilitic cachexia.

6. They prevent mercurial accidents.

7. They assist the curative effects of especial syphilitic remedies.

8. They are an excellent agent of proof whether or not a syphilitic individual is cured.

The physiological action of sulphurous waters (applied in form of potions, baths, or douches) consists chiefly in a vigorous excitation of the nutritive and absorbent organs of the economy, thus inducing not only a heightened tone of the digestive functions and increasing the resistance of the organism against the specific etiological entities (Lustgarten's bacilli?), but allowing also of a ready elimination of deposited foreign matter.

The aggravation of syphilitic troubles, mentioned above, is only an exceptional phenomenon, and occurs in persons who, while undergoing a thermal treatment, contract syphilis. The syphilitic cell proliferation is then found to be sustained, and even favored, and the indurations noted to progress speedily. In cases where chancres make their appearance the ulceration is likewise found to increase if the use of the water is persisted in.

Too active or too protracted an application of the sulphurous water may also aggravate the secondary symptoms.

The ingestion of mercurial salts continued, as it is often the case, for a year or longer, though favoring the reabsorption of the deposited matters, is very apt to prove a serious obstacle to the parenchymatous tissues by forming mercurial albuminates. The sulphurous waters will then render these products fluid, and make them enter the circulatory channels. At the same time they thus restore to the mercury its curative effects, and allow of its elimination from the system.

#### A PECULIAR PHENOMENON IN CEREBRAL, AND ESPECIALLY IN MENINGITIC, AFFECTIONS.

WHILE presenting a meningitic patient to the class on the 1st of December, Prof. Henoch, of the Berlin University, called attention to a peculiar symptom almost invariably observable in cerebral, and especially in meningitic, affections, which, on account of its diagnostic value, deserves to be remembered. The patient, on being examined, did not present any muscular contraction in either the legs or arms, but if the thigh was flexed at right angles to the abdomen, great muscular rigidity and contractions at once set in, which prevented the part from being extended.

The same phenomenon, though not so conspicuously, could be noted in the arm. This peculiar condition, Henoch said, pointed invariably to a cerebral affection, and possessed an especial value if the meningitic lesions were in the initiatory stage and presented few or no other symptoms.

Examining the literature of this noteworthy phenomenon, we find in the *Berl. Klinische Wochenschrift* of November 23, 1885, that Dr. W. Kernig, of St. Petersburg, was the first to describe this symptom, and to attempt to furnish a rational explanation of it. This author observed the stated symptom in fifteen cases of inflammation of the pia mater, thirteen cases of which were epidemic cerebrospinal meningitis, one a tubercular and one a purulent meningitis. Besides, he noted the same occurrence in six other cases, viz.: bloody extravasations of the cerebrum and the meningeal membranes, pachy- and leptomeningitis, after thrombosis of the transverse sinus. The symptom appeared in the beginning of the several affections, lasted during the entire course of the disease, and was even demonstrable after convalescence had set in.

We likewise find that Dr. Ed. Bull, of Christiania, observed this contraction symptom in three cases, one of which was a tubercular meningitis, the second a cerebral tumor, and the third a thrombosis of the transverse sinus.

An explanation of this singular phenomenon appears not easy, though it is evident that the contraction must be classed among the neuropathic spastic appearances. Its origin seems central, though a peripheral reflex influence may also participate in its causative agencies.

Examining in normal individuals the extended knee-joint, if the hip-joint is kept at the same time in a flexed position, we find that a perfect flexion of the knee is usually only possible if the angle between thigh and abdomen amounts to but little less than 90°. If, on the contrary, the thigh is flexed strongly towards the abdomen, forming an acute angle, the knee-joint cannot be made to form an angle of 180°; the knee forms an obtuse angle, and a further flexion is prevented by the tension of the muscles on the back of the thigh. These remarks are not superfluous, as they show that under normal conditions a similar contraction occurs, which of course ought not to be mistaken for a symptom of meningitis. To avoid errors, it is best to bend the knee-joint at an angle of 90°, which is most appropriately effected by

making the patient sit on the margin of the bed.

#### HOW OUGHT "ANTIPYRIN" TO BE SPELT?

THE name of "antipyrin" is, we believe, uniformly spelled in the German journals "antipyrin," whilst the English, and probably most of the American, journals spell it with the termination of "ine." For the purposes of correct nomenclature it is important that some decision should be reached as to what really is correct in the matter. To do this it is essential that the chemistry of it be understood, and we therefore give a brief abstract of such chemistry.

Di-methyloxyquinizin, or di-methyloxychin-*isin* (German), is prepared from methyloxyquinizin, the formula of the latter being  $C_{10}H_{10}N_2O$ .

Di-methyloxyquinizin, or antipyrin, according to its formula, is two molecules of methyloxyquinizin minus two atoms of hydrogen, as

$$2C_{10}H_{10}N_2O - 2H = C_{20}H_{18}N_4O_2$$

Methyloxyquinizin.      Di-methyloxyquinizin, or antipyrin.

Di-methyloxyquinizin possesses most of the chemical properties of methyloxyquinizin. It is chemically a base, and also an acid. Its acid-salts are destroyed by the action of water. From an alkaline solution it is precipitated by carbon di-oxide ( $CO_2$ ). Ferric chloride produces with it in solution a deep red coloration, and will show its presence down to the  $\frac{1}{100000}$  part. In dilute solution of antipyrin, nitrous acid produces a bluish-green color, delicate to the  $\frac{1}{10000}$  part. In concentrated solution of the substance nitrous acid causes the formation of green crystals. These reactions depend upon the formation of iso-nitroso-antipyrin  $= C_{20}H_{18}N_4O_2$ .

A study of the chemistry of antipyrin shows that there really is a room for doubt as to what the nomenclature should be. It is well known that the termination "ine" is used in the British and United States Pharmacopœias to name an alkaloid. From one point of view antipyrin is an alkaloid, and deserves therefore the termination "ine." On the other hand, it is also an acid, and the termination "ine" is repulsive to its nature: scientifically here is a dilemma. It is important to decide whether this creature is fish or fowl, but it must be remembered that antipyrin is a proprietary medicine, since it is a chemical compound whose discoverer has patented it and in doing so has named it. Under these circumstances, when there is a doubt as to the scientific accuracy, it seems to us that the name

should be spelt as the discoverer himself spells it, and in the original article it was spelled "in." We therefore think that "antipyrin" is more correct than "antipyrine," and shall endeavor to spell it hereafter in this journal "in." Only, however, when the seal of authority is given by the United States Pharmacopœia either to "in" or "ine" can the point be considered definitely settled. Whichever way the learned men who preside over the pharmaceutical destinies of the United States decide, we will bow with due submission.

#### VACCINATION.

THE relation of the number of vaccinia pustules to the protective influence of the vaccination has recently been made the subject of elaborate study by a German Commission, with results which are so important that we hope our readers will give them their due weight. The almost universal custom in this country is to vaccinate in a single place, but the Commission came to the conclusion that two is the minimum number of pustules which ought to be made in a protective vaccination, and some of the members affirmed that three is the least proper number. Dr. R. Koch, of the Stockwell Hospital, found that out of seven hundred and three smallpox patients, of those having no scars there died 47 per cent.; poor scars 25 per cent.; one good scar 5.3 per cent.; two good scars 4.2 per cent.; three good scars 3.3 per cent.; four or more good scars 1.1 per cent. He believes that the protective power of vaccination is in direct relation to the number of vaccinia pustules. It has been an American custom to vaccinate upon the arm, and we well remember the late Prof. Pepper telling in his lectures how that a baby, throwing its arm suddenly, knocked the charged lancet out of his hand, when, as ill luck would have it, the point struck the end of the little nose, and of course the vaccination took at that place. The infant grew to be a Philadelphia belle, who to her dying day never forgave the doctor for having put the seal of his protective goodness on the end of her nose. There is no sense in disfiguring the arm with a vaccination-mark. According to our opinion, vaccination should always be practised in the upper portion of the leg or the lower part of the thigh, and, in the light of the German researches, there should be at least three insertions; probably it would be better to utilize both legs.

A NEW AMERICAN SCIENTIFIC PUBLICATION.

FIRST-CLASS original researches in scientific medicine are so rare in America that the advent of a new series of publications seems to us worthy of editorial notice. We have looked over, with great pleasure and pride, the studies from the laboratory of physiological chemistry of the Sheffield Scientific School of Yale College, recently put forth under the supervision of Prof. R. H. Chittenden. Such of the articles as have direct bearing upon therapeutic problems will be noticed separately in the department of Progress, and therefore no analysis of the volume is here required. It does seem right, however, to congratulate Prof. Chittenden in being so placed that he is able not only to obtain time for research, but a definite channel of publication, and also to congratulate Yale College on having found a professor who is both able and willing to contribute original matter of great value to the world's store of scientific knowledge.

BACILLI IN LAUDANUM.

THE bacillus-craze has slain another Spanish victim. Dr. Don G. Puerta (*El Siglo Medico*, No. viii. 85, p. 578) has detected bacilli, which look exactly like Koch's cholera-bacilli, in various specimens of tincture of opium. The microbes showed a distinct motion, and appeared especially numerous in the precipitate on the sides and bottom of the vessel.

We do not see anything remarkable in the fact that a vegetable infusion of long standing should show fungi and microbic life; but possibly Dr. Puerta thinks he has discovered the true specific germs of cholera; if so, he will have to fight it out with Koch and Pettenkofer: or can it be that the bacilli are the cause of the *vis dormitiva* of opium?

DR. ROSE'S PAPER ON ANTISEPTICS.

ATTENTION has been called to the fact that Dr. Rose, in his paper published in our November issue entitled "Some Remarks on Antiseptics," etc., speaks of a three per cent. solution when the ingredients evidently make a one and a half per cent. solution. Dr. Rose informs us, in response to our query, that the proportions are correct, but that he fell into the mistake of calling the solution a

three per cent. instead of a one and a half per cent. by following Von Bruns, who, employing the same formula, termed it a three per cent. instead of a one and a half per cent. solution.

Reports on Therapeutic Progress.

TREATMENT OF CHRONIC GONORRHOEA.

The cure of a chronic gonorrhœa is so difficult and rare that the affection is almost regarded as an opprobrium of the profession. There are men who are troubled by the "morning-drop" for years in spite of every known medication. An especial danger of the chronic gonorrhœa is its proneness to resume an acute nature. Family disturbances are not infrequently caused by the presence of this affection in the husband, on account of the indisposition of the latter to fulfil his marital obligations. We agree with Dr. CASPAR, of Berlin, in blaming not so much the lack of efficiency of the usually employed medication as its improper application. Dr. Caspar's essay on the subject, appearing in the *Berliner Klinische Wochen.* of December 7, 1885, contains some instructive suggestions which invite our interest.

Examining the anatomical relations of the parts implicated in gonorrhœa, we find the male urethra to be a tube of fifteen to eighteen ctm. long, which is so materially different in its various portions that it is *a priori* improper to designate the affection of every portion collectively as gonorrhœa. The pars membrana and prostatica ought to be as strictly separated as is the cervix uteri from the fundus. An inflammation of the pars spongiosa need not necessarily affect the pars membrana, and *vice versa*. Most chronic gonorrhœal affections are situated in the bulb, or in the border-lines between the bulb and the pars membrana. Of one hundred callous strictures, about seventy occur in the stated regions, twenty in the fossa navicularis, and ten only on other localities of the pars spongiosa. These are the favorite seats of chronic gonorrhœa, though, of course, we occasionally find a gonorrhœa in the posterior portion of the urethra. Still, these are exceptional cases. We have, hence, to deal with a gonorrhœa which is either an anterior one, an anterior and posterior one, or a posterior one solely.

Most of the ordinarily-employed therapeutic interferences in gonorrhœa are useless. This is especially true of the inevitable injection, which does not go beyond the musculus com-

pressor unless an inordinate pressure is used. When the liquid impinges on this sensitive region the musculus compressor closes the urethra by reflex action, and forbids the entrance of the liquid beyond. The mere manipulation of drawing the hand from the meatus to the musculus compressor upward does not remove the spasm of the urethra, as has been asserted by some authors.

The most important matter is to decide whether the gonorrhœa is an anterior or a posterior one, which can be readily done by noting the behavior of a fluid injected into the urethra by means of a catheter. If the fluid flows out from the sides of the catheter, we know that the point of the catheter rests before the musculus compressor; if the fluid is neither ejected from the sides nor from the mouth of the catheter, we can be assured that the point of the catheter rests in the posterior portion of the urethra. But if the fluid returns directly by the mouth of the catheter, we know that its point rests in the bladder. This recognition is, of course, of the highest practical importance. We draw, hence, the following conclusions: Everything that collects in front of the musculus compressor returns by the urethral orifice; everything that collects in the posterior urethra flows in the bladder, on account of the inferiority of the internal sphincter muscle regarding the musculus compressor. This will suffice to determine the differential diagnosis between an anterior and posterior gonorrhœa. If the lips of the urethral orifice are glued together, or a few drops are noted in front of it, or if the clothing shows pus-spots, we can be reasonably certain that the affection is situated in front of the bulb. If these conditions are absent the correct diagnosis is less easy. Often the patients complain of a certain prickling or burning sensation on a certain circumscribed region of the urethra, which of course is then to be regarded as the seat of the gonorrhœa. At other times we succeed by examining the urethra with the button-sound and marking the sensitive spot. If a frequent desire to urinate should be found to exist, we can conclude that we deal with a posterior gonorrhœa. If alongside of this desire to urinate frequently pus-drops appear on the meatus, or its lips are glued together, or pus-spots are found on the clothing, we probably have an anterior and posterior gonorrhœa combined, although the absence of the stated desire does not justify the assumption that there is no posterior gonorrhœa existing in a given case. In the acute

posterior gonorrhœa we find invariably the desire to urinate frequently, while in the chronic form this symptom is often absent. The endoscope occasions necessarily so much pain that its employment is not advisable.

The following method of arriving at the proper diagnosis is preferable: The patient, after having not urinated for five or six hours, is asked to urinate into two glasses. If the first portion of the urine has a flocculent appearance, while the second remains clear, we have to deal with an anterior gonorrhœa; if, however, both portions are turbid, we have a posterior gonorrhœa. These symptoms, however, have a diagnostic value only in cases with a considerable secretion. In these cases we are, besides, certain to find the drop on the orifice, the gluing together of the lips of the meatus, and the pus spots on the clothing, if the gonorrhœa be an anterior one. Likewise would a considerable secretion in the posterior urethra, by flowing into the bladder and rendering all the urine turbid, make itself distinctly known. If, however, the secretion is so small that it could not reach the meatus nor the bladder respectively, we would have the following results:

1. In both cases we would find no traces of the catarrh on the urethral orifice.
2. In both cases the first portion of the urine would be flocculent, as the secretions are rolled up, as it were, by the first portion of the urine, and driven out of the urethra, no matter in which section of the urethra these secretions are situated.
3. In both cases the second portion of the urine will be clear.

In most cases, however, the mentioned method suffices to arrive at the proper diagnosis.

The difference between a cystitis and a posterior gonorrhœa is easy enough. In both affections both portions of the urine are turbid, but in posterior gonorrhœa the first portion is necessarily more turbid than the second one, while in cystitis just the reverse condition takes place. This latter fact is brought about by the pus settling according to the law of gravitation in the deepest portion of the bladder, and being ejected only by the last portion of the urine.

Basing on these views, Ultzmann constructed his well-known instruments, which are usually employed with great success.

If, however, a stricture has been forming or is about to form, the named instruments will be found to be insufficient.

It is well known that the gonorrhœal inflammation in contradistinction of a urethritis does not limit itself to the mucous membrane of the urethra, but enters the submucous tissues, the corpora cavernosa, and muscles. The product of this inflammation is a cellular infiltration of the affected parts, which leads to cicatricial tissue, and forms a stricture. At the same time epithelial cells are being constantly formed on the mucous membrane, the death and exfoliation of which furnish the material for the secretion of the chronic gonorrhœa. The glands and lacunæ Morgagni, and even Littre's glands, participate in the morbid process. Dittel regards the characteristic gonorrhœal threads and the goutte militaire as the product of the catarrh of Littre's glands and of the sinus Morgagni. We thus gain the conviction that even in absence of an actually existing stricture the entire gonorrhœal process must be regarded as the forming stage of a stricture, or, as Otis calls it, a stricture of a wide calibre. At the same time we can now understand that astringent and antigonococcic medicines cannot cure a gonorrhœa.

A radical cure must combine means to eliminate the cellular infiltration and to heal the catarrh. Hence the so-called progressive sound-treatment proved successful in many cases, and Unna's method, to employ bougies invested with a soluble medical coating, initiated a new and thoroughly satisfactory era for the treatment of gonorrhœa. The modification of Unna's bougies, introduced by Dr. Caspar, of Berlin, will be certain to prove a great improvement, and ought to receive a careful trial with us. Caspar constructed a sound of German silver having numerous canals on its body. The sound is slightly conical, and twenty-five cc. long. It usually has about six of the stated canals, which are of a depth of one and a half mm., and flatten off toward their anterior portion, and are wholly absent at a distance of five cc. from the point of entrance. (The instrument is manufactured by W. Tasch, Berlin, Schloss-freiheit.) These sounds are invested with an ointment-mass, which in a melted condition is poured into the canals, where it soon grows solid.

As ointment-mass the following recommends itself :

Cacao, 100 parts ;  
Cer. flav., 2-5 parts ;  
Argent. nitr., 1 part ;  
Bals. Peruv., 2 parts.

A three per cent. resorcine-ointment might

also be used, but it is in no way superior to the above mass. The *modus operandi* is as follows : Two teaspoonfuls of this mass are placed in an evaporating vessel having a mouth, and warmed over a flame slowly and carefully. The vessel ought not to attain a degree of warmth which prevents it from being touched by the hand. After the mass has melted, the canals are filled with it and allowed to solidify. The instrument must be thoroughly round and smooth. The anterior smooth part is to be anointed with vaseline in order to allow of a painless and easy entrance into the urethra. The instrument guarantees that the medicine reaches the exact locality on which it is needed. The sound passes beyond the stricture, and the ointment melts at the temperature of the urethra in course of a few minutes, and can thoroughly medicate the affected portion.

Ten to twenty applications are, according to Caspar's statement, usually sufficient to cure even an obstinate case of chronic gonorrhœa. Thirty of the most rebellious gonorrhœal affections were cured by him permanently, although fourteen of them had lasted over six months, and six over one year.

#### POISONING BY HOMŒOPATHIC TINCTURE OF BRYONIA.

DR. CRAIG DIXSON reports in the *Australian Medical Gazette*, October, 1885, that he was called to see a man, aged 63, in a state of collapse, and evidently suffering from the effects of some narcotic irritant. He had vomited freely ; the pulse was imperceptible at the wrist ; the patient drowsy and livid, and covered with cold perspiration. There was no diarrhœa, nor was there any complaint of pain. The patient was delirious, and yet could be made to give a kind of answer to a question. The history given was as follows :

The patient had been in the habit of dosing himself with homœopathic remedies, and among other drugs had a decoction of caraway-seeds and dandelion, which he called his diuretic mixture. He had also a bottle of smaller size containing pure mother-tincture of bryonia.

He was suffering from an attack of gout on the present occasion, and had asked his son for a dose of the diuretic mixture, and the son, by mistake, gave him a large teaspoonful of bryonia in water,—about  $\text{m} \text{ lxxx}$ .

The patient thought that it had not the usual taste of the diuretic mixture, and so

asked to see the bottle from which the dose was taken. The correct bottle containing the caraway and dandelion was then handed to him by some other member of the family, and so he thought that he must have taken the right mixture.

About two hours after this he took his usual dose of 5 drops of strychnine solution, which he was in the habit of taking, and almost immediately after he felt an uncomfortable, tickling, warm feeling in his throat, and very quickly commenced to vomit. Between the initial and last dose he had performed some important business, and, in fact, had been conversing as usual with several people on business matters.

Within a few minutes after the vomiting, which succeeded the last dose,—*i.e.*, the strychnine,—he became oblivious of his surroundings, having a feeling just as if a piece of gauze had been gradually drawn over his face. He then shut his eyes and remembered no more except Dr. Dixon's calling him by a wrong name when he came in. Dr. Dixon was at once sent for by his family. He thought at first the patient would die, especially since it was very difficult to get him to take any medicine by the mouth. However, by dint of perseverance, strong stimulants, as ammonia, nitrite of amyl, coffee, etc., with heat to the extremities, the doctor got the patient out of danger in about one hour and a half.

This case is interesting, as poisoning by bryonia is certainly uncommon, and it is regarded as a simple irritant poison.

The usual symptoms are giddiness, intoxication, or delirium, vomiting, colic, purging, and coma.

Experiments on animals have proved that it causes inflammation of the stomach and intestine.

The fresh plant applied to the skin produces vesication.

Woodman and Tidy (1877) only make reference to three recorded cases, two of which appear to be culled from the French, but the dates are not given. The third appeared in the *Lancet*, 9th May, 1868.

Of the two former cases one is recorded to be a male adult, who took an infusion of the root for ague. Symptoms were purging, followed by death.

The second case is a female adult, who took one ounce of decoction—part by mouth, part by injection—to stop the milk. Symptoms are not recorded, but death followed in four hours.

The *Lancet* case occurred in the person of

a child of 3 years (female), who took the berries. Giddiness came on in half an hour, furious delirium during night, vomiting, diarrhoea, dilated pupils, and coma, and death in thirty hours.

#### PHYSIOLOGICAL ACTION OF SULPHATE OF FUCHSINE AND SAFRANINE.

While everybody knows that, especially the cheaper and still beautifully colored, red wines do not solely owe their purple lustre to the coloring-matter of the grape, few persons are probably aware that highly poisonous materials are occasionally, if not habitually, employed to produce this fraudulent coloration. Slight constitutional and graver gastric symptoms follow so frequently the ingestion of even small quantities of such wines that a close examination of their constituents is well indicated.

CAZENEUVE and LÉPINE communicated to the Academy (meeting of the 16th of November, 1885) their conclusions as to the physiological action of two drugs which are most ordinarily employed for coloring divers wines, *viz.*, the sulphate of fuchsine and safranine. We abstract the most salient points from a report of this communication as appearing in the *Gazette Hebdomadaire* of November 20, 1885.

The experiments refer to observations made both on animals and on man.

The sulphate of fuchsine was found to be in every way exempt from toxic properties.

The experiments made with safranine, which is the product of an oxidation of various substances, chiefly of aniline and pseudo-toluidone, gave the following results:

If a solution of safranine in salt water, in a proportion of 7 to 100, is injected into the veins of a dog, we perceive at once distinctly toxic phenomena. If a dose of  $\frac{1}{10}$  gr. to the pound body weight is given to a dog, we note almost immediately after the injection a conspicuous coloration of the mucous membranes, acceleration of the heart, with a shortening of the contractions, considerable dyspnoea, with marked expiration, and usually convulsive movements of the feet. After the expiration of a couple of hours, we observe intense coloration of the urine, often with albuminuria, without any increase, however, in the quantity of the urine. After an abundant diarrhoea, lasting for several days, the animal perishes. If the doses be doubled, the stated symptoms make their appearance much more rapidly and in a more pronounced manner.

It is possible even that death takes place by respiratory failure before the injection is finished. Making an autopsy, we find the following conditions: The heart is very large, and in its diastolic phase; the lungs are healthy, neither congested nor colored; the peritoneum is injected, likewise the gastric and vesicular mucous membranes, which show a much stronger hyperæmic condition, however; the bile is scanty, and has a decidedly reddish appearance. If safranine is ingested in form of a powder by a dog in a dose of 15 to 60 grs. daily for a period of several weeks, diarrhoea is the only noted symptom, as the irritation of the drug on the intestinal tract, and subsequent copious evacuations, prevent the absorption of its active principle.

#### THE PHYSIOLOGICAL ACTION OF TOBACCO.

In the Fiske Fund Prize Dissertation, No. XXXIV., entitled "The Physiological and Pathological Effects of the Use of Tobacco," recently published by Messrs. P. Blakiston, Son & Co., of Philadelphia, the author, DR. HOBART AMORY HARE, presents the facts and arguments that have led him to the following conclusions:

1. Tobacco-smoking does not decrease the urine eliminated, but rather increases it.
2. Tobacco does retard tissue-waste.
3. Tobacco and its alkaloid cause convulsions in the primary stage of the poisoning, by depressing the reflex inhibitory centres in the cord.
4. It causes the palsy of the second stage, by paralyzing (a) the motor nerve-trunks, (b) the motor tract of the spinal cord.
5. The sensory nerves are not affected by the drug.
6. Nicotine contracts the pupil, by stimulating the oculo-motor and paralyzing the sympathetic, this action being peripheral.
7. Nicotine primarily lowers the blood-pressure and pulse-rate; (a) secondarily increases pressure and rate; (b) thirdly, decreases pressure.
8. The primary lowering of pressure and rate is due to pneumogastric stimulation, associated with vaso-motor dilatation.
9. The secondary stage is due to vaso-motor constriction and pneumogastric palsy.
10. The third stage is due to vaso-motor dilatation returning.
11. Death in poisoning from this drug is due to failure of respiration, the action of the drug being centric.
12. The blood-corpuscles are broken up and crenated by the action of the poison.
13. In death from nicotine-poisoning the blood shows changes in *spectra*.
14. Death

can be brought about by the cutaneous absorption of nicotine. 15. Tobacco increases intestinal peristalsis in moderate amounts, and produces tetanoid intestinal spasms in poisonous doses. 16. The liver seems to destroy the poison, although this destruction is participated in by any set of capillaries in other parts of the body. 17. Tobacco-smoking increases the pulse-rate and decreases arterial pressure.

#### ON THE PHYSIO-PATHOLOGY OF FEVER.

Our space, unfortunately, does not permit us to give more than an epitome of the highly interesting study of PROF. E. MARAGLIANO on the physio-pathology of fever as appearing in the *Centralblatt für Medicinische Wissenschaften* of November 14, 1885.

Maragliano has studied during the last three years the behavior of the vessels of the skin in beginning and in receding fever, with the hydroplethysmograph of Mosso, often eight to ten hours without interruption. A first series of observations was made on patients who, in the course of the experiments, were spontaneously attacked by fever. The main results of these observations were the following:

1. A febrile temperature was found to be preceded by a progressive contraction of the vessels of the skin.

2. During the height of contraction—when the vessels attain their minimum lumen—we find the climax of the febrile temperature.

3. As long as the temperature remains at its highest level the contraction of the vessels persists.

A second series of experiments was instituted on patients in whom the fever set in after a previous reduction of the temperature to normal by antipyrin, kairine, and thalline. In these experiments Maragliano observed the same phenomena as stated above.

In a third series of experiments patients were used in whom the febrile temperature fell to normal during the experiment without the exhibition of antipyretics. The following results were here obtained: 1. The fever attack is preceded by a progressive dilatation of the vessels of the skin. 2. This dilatation increases simultaneously with the sinking of the temperature, and reaches its maximum when apyrexia appears.

These investigations prove the old theory of fever as advanced by Traube. Basing on the results of his calimetric examinations, Maragliano feels certain that in fever we have to deal with a retention of heat, with

concomitant ischæmia of the vessels, and in defervescence, with an increased thermal discharge, with a concomitant vascular dilatation. Still, our author does not by any means believe that the retention of heat is the sole cause for the fever. On the contrary, he is positive that still another factor, viz., increase of heat-formation, plays an important rôle in the causation agencies of fever. The increased production of urea and of carbonic acid gas furnish a satisfactory proof for the existence of this increased heat-formation. As to the true significance of this intensified combustion process, we require a good deal more of detailed knowledge. Possibly it is caused simply by an overheating, as it were, following upon the retention of heat.

Naunyn, Lehmann, and others have recently shown that if animals are subjected to an artificially effected rise of temperature, they give off more urea and carbonic acid. Maragliano has observed the same phenomenon in men if they are subjected to a heightened temperature, such as in consequence of warm baths.

At any rate, there is no doubt that an increase in the heat-production takes place, no matter what causes the latter might have. Therefore we can conclude that the rise of temperature in fever is caused by both a heat-retention and an increased heat-production. This does, of course, not exclude the presence of other still unknown factors.

The experiments and observations made in this connection on various antipyretic drugs are equally interesting.

The first series of experiments were made with kairine, antipyrin, thalline, the salts of quinine, and salicylate of sodium, on individuals who were perfectly afebrile and healthy. The results obtained with Mosso's hydroplethysmograph and Winternitz's calorimeter were as follows:

1. All employed antipyretics cause in apyretic individuals a considerable vascular dilatation.

2. They cause also an increased discharge of animal heat.

3. They produce a fall in the excreted carbonic acid gas.

A second series with these drugs was made on fever patients, and gave the following results:

1. The antipyretic effects of these drugs are caused by a vascular dilatation. When their influence is exhausted, vascular contraction and subsequent rise of temperature ensue.

2. During the period of their activity increased discharge of heat invariably takes place. After their exhaustion the heat-discharge decreases, and the temperature rises again.

3. The influence to antipyretic drugs is intimately connected with a reduction of the oxidizing processes within the economy.

As a general conclusion to Maragliano's valuable researches, we can advance the theory that antipyretic remedies act by being able to eliminate the two most important pathogenetic causes of fever. In other words, they prevent vascular contraction, and the thus resulting storing up of animal heat, and increase the heat-discharge; besides, they combat successfully the increase of heat formation by reducing the intensity of the oxidizing processes of the economy.

This double action of the antipyretic drugs is probably caused by an influence exerted on the innervation of the vascular system and the so-called trophic nerves. Possibly their action affects directly the medullary centres, which, according to the latest researches of Fano, exert a great influence on the nutrition of tissues.

#### EVISCERATION OF THE EYEBALL BY THE NEW METHOD.

At a meeting of the Baltimore Academy of Medicine, held December 1, 1885, Dr. J. J. CHISOLM (*New York Medical Journal*, December 19, 1885) related a case of evisceration of the eyeball after the plan recently recommended, which consisted in completely excising the cornea by means of a circular incision around its margin, the contents being then entirely removed, leaving the sclerotic intact. The advantage alleged for the operation was that the socket-tissues were not disturbed; neither was the muscular apparatus of the eye interfered with; besides, the stump left made an admirable seat for an artificial eye. The operation itself was very simple, and could be performed much more expeditiously than complete enucleation, but convalescence was so very tedious, and at times gave rise to such painful and alarming symptoms, as had occurred in his case, that in future he should confine himself to the old plan of complete enucleation. It was his usual custom to allow a patient to go about his affairs very soon after the operation, at the outside in twenty-four hours, but in the evisceration operation, even up to the fourth day and later, there were such œdema and pain that he could

not think of allowing the patient to be from under his observation. He had never had such an experience with the old method.

ON THE INFLUENCE OF TEMPERATURE  
ON FILTRATIONS OF ALBUMINOUS  
SOLUTIONS THROUGH ANIMAL  
MEMBRANES.

From a very recent inaugural dissertation of A. Löwy (Berlin, 1885) on this subject we have gathered some principal points of interest. W. Schmidt has found that in filtrations through animal membranes (pericardium of calf) the quantity of the filtrate increased with the rise of temperature, while the relative percentage of solid residue-matter decreased. Löwy filtrated under a constant pressure (84.3 ctm. of the filtration-fluid) blood-serum and solutions of egg-albumen through animal membranes (pig-bladders, dried and softened first in water, then in serum) at a varying temperature. The surface of the filtering membranes amounted to 41.9 ctm. A loss of the filtration-fluid by evaporation was sufficiently guarded against. After a definite duration of the experiment, the quantity of the solid residue, its contents in organic and inorganic substances, were repeatedly determined. Löwy gained the conviction by a separate determination of the albumen that the organic substances consisted almost wholly of albuminous matters. He found that with a rising temperature, the quantity of the filtrate, the dry residue and its contents of organic substances rose constantly. The following table will serve to illustrate these facts with reference to the filtration of diluted blood-serum :

Temperature (C.).	Quantity (serum).	Solid residue. Per cent.	Organic Inorganic Matters.	
			Per cent.	Per cent.
16 $\frac{1}{4}$ °	8.8	0.17	0.14	0.039
35 $\frac{1}{2}$ °	15.98	0.33	0.28	0.072

In the majority of cases the relative quantities of the dry residue and of the organic substances are found to equally increase at a heightened temperature ; also the inorganic substances appear to filter in larger absolute quantities in a heightened temperature, though a rise of temperature influences them less than the organic substances. The following table is to illustrate these facts :

Temperature (C.).	Quantity (serum).	Solid residue. Per cent.	Organic Inorganic Matters.	
			Per cent.	Per cent.
13°	3.5	8.81	7.9	0.91
30°	9.95	7.61	6.7	0.94

In conclusion, we give the figures which

Löwy obtained with diluted serum (2.3 per cent. solid residue, of it 2.1 per cent. organic matters) under a temperature varying between 37.5° to 42° (C.).

Temperature (C.).	Quantity (serum).	Solid residue. Per cent.	Organic Inorganic Matters.	
			Per cent.	Per cent.
37.5°	6.0	2.32	2.05	0.27
42.5°	6.55	2.28	2.08	0.2

Even if the increase of solid matters, as shown by this table, is not a great one, the fact that a heightened temperature increases the filtration of albuminous solutions must be accepted as a physiological maxim.

TREATMENT OF LUPUS BY COLD.

Few diseases of the skin have within a comparatively brief period experienced so many changes of treatment as lupus. Nearly all of the therapeutic interferences in lupus aim at the destruction of the affected tissue, as is clearly the case with the caustic pencil, first recommended by Hebra, the sharp spoon, and the galvano-cautery. The sanguine anticipations in regard to the local employment of iodine and pyrogallic acid found but an imperfect realization, at least these drugs failed to show any specific antilupous properties.

The noteworthy discovery that the lupous tissues contained tubercle-bacilli has hitherto led to but few and practically little important therapeutic innovations. The fact, however, that the number of bacilli was found to be a very small one in every lupous tissue induced Koch, after a careful study of the subject, to assert that the low temperature of the integument formed a check to the development of the pathogenetic microbes of the affection. Basing upon these certainly very plausible conclusions of that distinguished bacteriologist, PROFESSOR GERHARDT, of Berlin, treated four cases of lupus that came under his observation by the application of ice, and communicated his clinical results to the *Deutsche Medicinische Wochenschrift* of November, 1885.

To avoid pressure, an ice-bag was suspended from a scaffold and lowered upon the affected part twice daily for three consecutive hours. It is to be added that the four cases under treatment had previously been subjected to every known mode of medication without experiencing any material improvement.

Gerhardt's ice-treatment, which was in every instance kept up for about a month, produced not only better results than were obtained by

all preceding therapeutic measures, but led to what could with propriety be called a temporary cure.

These experiments having been carried on very recently, Gerhardt is, of course, not yet able to tell whether or not relapses will occur.

At any rate, it is rational to assume that, provided we accept the tubercular and parasitic nature of lupus, the lowering of the temperature forms a powerful check to the growth of the microbes, and that cold is consequently an energetic therapeutic agent in lupus.

#### THE TREATMENT OF HYDROCELE AND VARICOSE VEINS BY CARBOLIC ACID INJECTIONS.

DR. LEONARD WEBER reports in the *Medical Record*, December 12, 1885, four cases of hydrocele which had been rapidly and painlessly cured by the injection of three ounces of a mixture of equal parts of carbolic acid, alcohol, and water. Of course this method of treatment will not answer in hydrocele where the sac is hypertrophied to any considerable extent. In such cases a radical operation and antiseptic dressings form the safest and best mode of treatment. Dr. Weber also states that carbolic acid has proved a safe and efficient remedy in his hands for the purpose of coagulating the blood in varicose veins, and obliterating them by adhesive inflammation; and he reports a case of severe varicose veins cured by the injection of four drops of carbolic acid into each sinus, entering the needle sidewise, and making a compression on the approximal and distal end of the sinus until a soft coagulum had formed. In treating hemorrhoids, the external hemorrhoids of small size may be obliterated by injecting a minim or two of carbolic acid, or, with a less risk of sloughing, four or five minims of a fifty per cent. solution of the acid.

A careful selection of cases of hemorrhoids suitable for the obliterating treatment by carbolic acid injections is highly commendable. With small, tense, and moderately bulging tumors of this kind good success will be rare, while the procedure is often painful, and not infrequently followed by inflammation. In a few cases, where this plan was employed by Dr. Weber, gangrene of the injected hemorrhoid supervened, and the dead mass came away under antiseptic dressings without any unpleasant local or general consequences.

Phlegmon, abscess, and subsequent fistula in ano, in consequence of injections either too strong or applied in cases in which this mode

of treatment was not advisable, have been seen. The possibility of ascending thrombosis and pyæmia under similar circumstances cannot be denied. Altogether, the cure of hemorrhoids by carbolic acid injections is a method neither as generally applicable nor so free from danger as it has been represented by some practitioners.

In operating it will be best to insert the needle about one-fourth of an inch from the base of the tumor, and push it through the sound skin directly forward into its central portion, taking good care not to spill any of the liquid along the track of the needle or at the point of entrance. This precaution is essential if we want to get obliteration of the pile by adhesive inflammation instead of seeing it slough away. The large and pendulous external hemorrhoids may be ligatured after incising their cutaneous parts, cut off, and the wound dressed with iodoform until the ligature comes away.

Whether we employ the ligature or thermocautery in external or internal hemorrhoids, it is good practice to stretch the sphincter ani in a moderate degree before proceeding to operate. Such distention not only facilitates the operation, but also prevents subsequent pain and discomfort, and promotes the healing of the wound.

Carbolic acid injections will not do for internal piles. They must be treated by the ligature, or the clamp and cautery, as described above.

Dr. Weber states that he has the records of four severe cases of external and internal hemorrhoids, three in males and one in a female, every one of which had between five and eight hemorrhoidal tumors within and without the sphincters. They all showed the symptoms of anæmia to a considerable degree. Three of them were operated upon with the clamp and cautery, one with the ligature, and they all got well without secondary hemorrhage or other unpleasant symptoms.

#### SULPHATE OF SPARTEINE.

M. GERMAIN SÉE, the eminent Parisian therapist, presented at a recent meeting of the Academy the results of his researches on the sulphate of sparteine, which served to arouse the highest interest in all present. Before discussing the remarkable statement of Sée it will be well to give an exact representation of his main conclusions regarding the drug, as published in the *Gaz. Hebdomadaire* of November 27, 1885.

Sulphate of sparteine is a cardiac regulator and a dynamic medicine of high power. The following are its most characteristic physiological effects as far as the circulatory system is concerned :

1. Its most salient action is to raise the power of both heart and pulse ; in this respect, however, it acts in a more pronounced manner, more promptly, and more constantly than either digitalis or convallamarine.

2. It regulates immediately a disturbed cardiac rhythm, and incomparably better than any other known drug.

3. It accelerates the beats of the heart in grave atonic conditions of both the heart and the general organism, and approaches in this respect belladonna.

All of these phenomena appear at the end of one or several hours, and persist three to four days after discontinuation of the medicine. During this period the vital energy of the entire system is raised and the respiratory act facilitated, though not so greatly as after the exhibition of iodide of potassium.

The urinary functions alone seem to remain unaffected, in the moderate doses at least in which Sée has hitherto employed the drug.

As to the indications of sulphate of sparteine, we can gain from the above statement a very clear and precise view. The drug suggests itself in the first place in myocardic weakness, no matter whether resulting from direct tissue-changes or from an insufficiency subsequent to compensatory efforts on circulatory impediments. If the pulse has become irregular, intermittent, and arrhythmic in the course of various cardiac or general affections, sulphate of sparteine should invariably and rapidly restore the normal condition by sustaining and augmenting the power of the heart.

So far, so good. It sounds well enough, and may even be precisely as stated by Sée. But we fail to note two very essential factors in the report : first, there is not the slightest mention made of any possible untoward after-effects, especially of an accumulative action, so dreaded in the case of digitalis, and then Sée's report lacks the indispensable basis of clinical trials and proofs, which we are very anxious to obtain.

#### BACTERIOTHERAPY.

In a recent number of the *GAZETTE* we gave a short account of Professor Cantani's experiment in "bacteriotherapy," in which a phthisical patient was subjected to inhalations

of bacterium termo. The result was that bacillus tuberculosis disappeared, and the condition of the patient was wonderfully improved. DR. SALAMA, of Pisa, according to the *British Medical Journal*, November 28, 1885, reports another case of the same kind. In a case of phthisis, with a cavity in the apex of the left lung and various patches of consolidation, Koch's bacillus disappeared within about a fortnight after the inhalations of the bacterium termo were commenced, all the other symptoms improving at the same time. Dr. Maffucci, Professor of Pathological Anatomy at Pisa, who verified the diagnosis, prepared the bacterium-culture. A few drops of spring-water were added to a sterilized solution of gelatin in meat-broth with peptone. After a day or two colonies of various micro-organisms made their appearance, and among them was the bacterium termo. Under the microscope, a sterilized platinum needle was dipped into this, and then introduced into another portion of the gelatin preparation. After two days this was found to be a pure culture of the bacterium termo. The contents of one test-tube prepared in this way served for one day's inhalations, being mixed with a meat-broth made from 150 grammes of beef to 200 grammes of water, and left for eight or ten hours, according to temperature. If left too long, the putrefaction became insupportable to the patient. Broth so prepared was given by Siegel's spray-producer every day in divided doses. Sufficient time has not yet elapsed to show whether the improvement was permanent. It is not quite certain that the bacterium was the sole agent of amelioration here. It is possible that the meat-broth may not have been without its effect ; and it is just within the range of supposition that the bacterium has a psychical influence on physician as well as on patient, not less important than its alleged bacillicide properties.

#### INJECTIONS OF CALOMEL IN SYPHILIS.

DR. NEISSER, professor at the University of Breslau, recommends in the *Deutsche Medizinische Zeitung* of November 30 his method of employing calomel hypodermically. He uses the following formula :

R Hydr. chlor. mit.,  
Sod. chlor.,  $\mathbb{A}\mathbb{A}$  5 parts ;  
Aque dest., 50 parts.

And injects a syringeful twice every two

weeks, or once every week, into the gluteal region, penetrating deeply into the tissues. Neisser claims that on account of the long-lasting and yet but very slowly-proceeding absorption of the mercury, this method is alongside of the inunction-cure to be regarded as the most efficacious and energetic treatment of syphilis. He has treated one hundred and twenty-two cases (fifty-four males and sixty-eight females) with these calomel injections, and feels quite gratified at the results. In rebellious and relapsing cases this method gave especially favorable results. The objections that can be urged against these calomel injections are that they occasion a good deal of pain, and not rarely produce infiltrations and abscesses, which untoward effects, however, can all be avoided by an ample ingestion of chloride of sodium, either as *an addition to the food or taken alone*.

The nozzles of the hypodermic syringes used in Germany are about one-third longer than those used in America, and are buried in the tissues in their full length. It is claimed that the danger of forming an abscess is lessened by entering the lowest strata of the connective tissue, or even the muscles themselves. The method as practised in America, however, gives such satisfactory results that there is no occasion to deviate from it.

#### ON THE DURATION OF THE ACTION OF MEDICINES.

At the last annual meeting of the British Medical Association, DR. D. J. LEECH opened the discussion in the Section of Pharmacology and Therapeutics on the duration of the action of medicines with a very valuable paper, containing many points which cannot fail to interest our readers, and we therefore publish a tolerably full abstract of his address.

In the treatment of disease by medicines we have to determine the frequency with which a drug must be given, as well as the quantity in which it should be administered. Experience doubtless aids us in deciding as to the periods which should intervene between successive doses of medicines; but in a large majority of cases the frequency of repetition is, to a great extent, a matter of routine. The custom of administering medicines at regular intervals of three or four hours—a little oftener when the case is severe, at longer intervals as it becomes milder—has come down to us from a time when the knowledge, both of disease and of drugs, was less advanced than it is now. Disease was formerly looked upon

as an enemy to be attacked and routed by medicine: if the enemy were in strong force, it was considered desirable that a strong fire should be maintained at short intervals. If he showed signs of retiring, the fire was slackened in its severity, in its frequency, or in both. The exact manner in which medicines effected the cure of disease was either not considered at all, or was the subject of vague speculation. But, at the present time, one of the leading objects of the therapist is to alter the functions of certain tissues or organs temporarily or permanently. Sometimes we aim at restoring the normal functions of parts, sometimes we desire to modify functions for a time, and thus neutralize evils arising from a disordered condition of other parts on which we cannot act. But whether our purpose be to restore or modify, we know it can rarely be attained except by acting on the tissues or organs we wish to influence, with a certain degree of continuity; and we should endeavor, therefore, to repeat our medicines in such doses, and at such intervals, that the continuity of action we desire may be attained.

If this be so, it is manifest that our knowledge of the length of time during which a medicine can be counted on to act on any organ ought to play an important part in our decision as to its repetition. Unfortunately, our information as to the duration of action of some drugs is very limited, and the causes which lead to variations in duration are only obscurely known to us.

Now, first of all, the question may be raised, Does our present knowledge support the view that medicines act during definite periods; that is, can we rely on a given dose of a drug influencing the organ in which it acts for the same space of time in different individuals, or on the same individual at different times?

It must be confessed that some of our experiences seem at first sight to give a negative answer. We know that if a number of persons take a poison together, the effects may commence and terminate at different times. A dose of arsenic may cause violent symptoms in ten minutes, but ten hours may elapse before evidences of poisoning appear, and the period at which death occurs may vary in a corresponding manner.

Differences with regard to the effects of poisons can be, to a great extent, explained by differences in the rapidity with which the absorption commences. As long as a poison remains quite unabsorbed in the stomach, it cannot, of course, exert its usual effects on other organs; and toxic substances seem at

times to influence the stomach in such a manner that absorption is materially delayed.

Drugs in medicinal doses are less liable to raise up barriers to their own absorption, but a very slight alteration in the condition of the stomach may delay the solution of the materials which, ordinarily, are quickly digested; and there can be little doubt that drugs, even in medicinal doses, may at times remain long unchanged after they are swallowed. Sometimes they are then rejected. Most of us have seen cases in which a dose of medicine has been returned after a sojourn of an hour or two in the stomach. But sometimes absorption at length takes place, and then the ordinary physiological effects appear, though at a late period. Deferred absorption, probably, accounts for most of those instances in which the action of medicines is unduly delayed.

When the absorption of a drug commences without any unusual delay, the duration of its action will depend chiefly on the time required for the completion of this process and on the rapidity with which excretion of the drug takes place. It will likewise be influenced by the susceptibility of the part affected, for we may well suppose that the more powerfully an organ is acted upon, the longer will the disturbance in its functions continue, even though the cause of the disturbance has passed away. Now, susceptibility of an organ to the influence of a drug may vary considerably in different people, and likewise in the same individual, according to the state of health and other circumstances.

Manifestly, the conditions which regulate the duration of the actions of medicines are exceedingly complex. Apart from exceptional circumstances connected with absorption, however, Dr. Leech shows that many medicines do act for tolerably definite periods; and, in some cases, it may be possible to determine the average time of action of individual doses with sufficient exactness to serve as a guide to repetition.

In the first place, it may be pointed out that experience has already made us aware of relative uniformity in the period of activity of many drugs. Ammonia acts quickly on the heart, and its effects soon pass away; the tonic effects of digitalis are slow to appear, but they last a long time. Of our diuretics, purgatives, and emetics, some act for a shorter, some for a longer, period. The diuretic effects of caffeine, for example, soon cease when we stop the administration of this drug, while the increased flow of urine which is produced by

digitalis usually goes on for a long time, sometimes for several days, after the medicine has been discontinued. The difference in the period during which these two drugs act may of course depend on the fact that they exert their influence on different tissues. Caffeine, it has been suggested, stimulates the tubular epithelium, while digitalis causes diuresis through its effects on the vascular system. But the relative difference in the duration of action must certainly be dependent on the fact that each influences the tissues it affects for a more or less definite period. We find, too, that when drugs act in a similar manner on the same tissues, the relative periods of their activity may vary distinctly.

The symptoms of intoxication produced by alcohol can be reproduced by ether, and there can be little doubt that, in inducing their usual results, these two drugs affect the same tissues and functions. But each stage of intoxication is shorter, when caused by ether, than when it is due to alcohol, and, as the relative difference of activity is always to be observed, it is manifest that the duration of the influence of these two drugs, on the parts of the body they affect, must be, within certain limits, definite. What these limits are has not yet been ascertained; but in the case of a class of drugs which yield symptoms capable of graphic representation, the limits of duration may be, to a certain extent, demonstrated.

The marked phenomena produced by the inhalation of nitrite of amyl, and the resemblance between them and those which follow the administration of other nitrites and nitro-glycerin, have been made known to us by the investigations of Drs. Brunton and Cash, Dr. Murrell, Dr. Hay, and others; but all who have made observations on the comparative effects of these substances have noted the great difference there is between the duration of the influence of the amyl compound and that of the other nitrites and nitro-glycerin. Dr. Murrell has pointed out that, while the influence of amyl nitrite is very transitory,—a tracing taken a minute and a half after the inhalation of the drug appearing normal,—the full action of nitro-glycerin is not observed in the sphygmographic tracing till six or seven minutes after the dose has been swallowed, and the tracing does not assume its normal condition for half an hour. Dr. Hay has further drawn attention to the fact that nitrite of sodium checks anginal pains for a longer time than nitro-glycerin, from which it follows that the influence of the alka-

line nitrite on arterial tension persists longer than that of the glycerin compound.

But it has been noticed, too, that the phenomena produced by the nitrites and nitro-glycerin vary not a little in different individuals.

Some people, for example, are powerfully affected by half a drop of the one per cent. solution of nitro-glycerin, while many can take five drops, or often a larger quantity, without feeling any sense of discomfort. Dr. Leech therefore determined the period during which nitro-glycerin and the nitrites depressed the circulation, and has administered these drugs in various doses to individuals differing considerably in susceptibility to their effects, the subject in all cases being free from cardiac disease. He found that the influence of amyl nitrite on the pulse commenced immediately after its inhalation; the arterial tension is reduced to its lowest point in from thirty to sixty seconds, and the blood-pressure then rises again, and usually attains its ordinary height in a minute and a half, though at times the normal tension is not reached for two to four minutes, and sometimes a fall of tension follows in a few minutes after an apparent recovery. This is succeeded by a subsequent rise and improvement, and a third or slight fall, so that the effects of the nitrite may be traceable by the sphygmograph for twenty minutes to half an hour. The duration, then, of the effects of the nitrite of amyl varies considerably. Its very marked tension-reducing influence never lasts more than one and a half to two minutes, but a slight depression of blood-pressure is commonly present for a longer period, and not only does the duration of the influence of the amyl nitrite differ in different people, but it is also variable in the same individual at different times. Of two successive doses, the influence of one may be traced for half an hour, whilst the effects of the other may disappear in the course of a few minutes; but this remark only refers to the slighter effects, very distinct lowering is of the same duration in all.

The nitrite of ethyl depresses tension for a much longer time than amyl nitrite, and in a different manner, since seven or eight minims of pure ethyl nitrite will usually keep the tension distinctly depressed for at least forty-five minutes, in some people for rather more than an hour; and the circulation is often influenced during the whole of the second hour after administration. The depression of the tension, though more prolonged, is not so great as that produced by nitrite of amyl.

Nitro-glycerin acts more quickly and more powerfully than nitrite of ethyl; its effects, too, are more prolonged. A single drop of a one per cent. solution usually causes a fall in the pulse-tension in one and a half to two minutes, and in three or four minutes the fall is well marked. The blood-pressure continues low for about ten minutes, sometimes a little longer; then it gradually rises, and in half an hour may be almost normal. But, after this, oscillations commonly take place, and the normal standard is not usually perfectly attained for an hour to an hour and a half after the drug has been given.

The duration of the effects of the alkaline nitrites is more prolonged than that produced by the nitro-glycerin, but they are not so rapidly produced. In most cases ten minutes elapse before the tension falls markedly, but a slight change is seen within the first five minutes. The size of the dose exercises only a slight influence on the time of commencement, but those who are very susceptible to the action of nitrites are affected in six minutes as strongly as ordinary people are in ten. After the first ten minutes the pressure falls rapidly, and it remains usually very low from the end of the first half-hour until about two hours have elapsed from the time of administration. These experiments seem to show that nitrite of amyl acts powerfully almost at once, and for two minutes, but its influence on the pulse may often be traced for ten to twenty minutes, sometimes longer. The effects of nitrite of ethyl are seen but five to twenty minutes after its administration, but remain very visible for an hour, and are perceptible for one and a half to two hours. Nitro-glycerin powerfully affects the circulation in two minutes; its influence is most marked for thirty to forty-five minutes, and may be detected for two and a half to three hours. The alkaline nitrites produce but little influence on pressure for from six to ten minutes, but then depress it strongly for two and a half hours, and act altogether for between four and five hours. Cobalt yellow begins to act markedly in from twenty to thirty minutes; its tension-depressing effects are often very pronounced for more than three hours, and sometimes visible for six hours.

The times named are, of course, averages. As Dr. Leech has pointed out, the period during which drugs act on individuals is influenced by the natural susceptibilities of the organs affected, by the dose, and by the condition of the absorptive and excretive powers. It therefore follows that the duration of action

must differ within certain limits, not only in different individuals, but also in the same individual at different times.

The state of the organs connected with absorption and excretion is hardly ever the same for any length of time, and so it comes to pass that even consecutive doses in the same individual often vary, to some extent, in the period of their action. If, however, we can arrive at some idea of the average time during which we can count on single doses of our medicines acting, and the limits of variation in duration under different conditions, we shall have gained much.

Susceptibility can usually be determined by experiment, and sometimes judged of in other ways. In the case of the nitrites, for example, a single administration, if carefully watched, may enable us to decide as to whether the subject is easily affected or the reverse; but we may form an opinion on this point from the general characters of the circulatory system. The anæmic, and those of weak circulation, are usually powerfully affected by tension-depressants; those who have a high arterial tension are not so readily influenced.

The benefit derived from these researches is well seen in the case of the nitrites, since through them we have now the power for depressing arterial tension for any time we like. We may influence it for a few seconds; we may keep it low for hours; and when we consider the advantages which accrue in certain conditions from lowered tension, it is manifest that we have acquired almost a new therapeutic power.

#### *ACTION OF MERCURY ON THE BLOOD IN SECONDARY SYPHILIS AND IN ANÆMIA.*

The introduction of the hematimetric method into the experimental researches of therapeutics insures a precision and exactness of investigation unattainable by the older observers. The influence of the salts of mercury on the circulation—this old and highly important topic—has been recently the subject of a most thorough and strictly scientific clinical study by DR. L. GAILLARD (*vide Archiv. Générale de Médecine*, November, 1885). The subjects on whom the first series of observations was instituted comprised,—

1. Syphilitic patients without or with a slight anæmia.
2. Syphilitic individual with an advanced state of anæmia.
3. Syphilitic individual also with an ad-

vanced state of anæmia, but in a condition of mercurialization.

Gaillard's conclusions are as follows:

In the first group a diminution of the number of blood-globules and of the hæmoglobin could be observed in the course and at the end of the mercurial treatment.

In the second group a favorable result could rapidly be noted, both the number of blood-globules and the hæmoglobin increasing considerably and in a short time.

The subject of the third observation was not improved. The anæmia had no tendency to disappear, even after the effects of mercurialization had passed away. There was an evident intolerance of the drug, which must be borne in mind both regarding prognosis and the estimation of the therapeutic result.

Comparing these results, we see that the second category, representing syphilis and anæmia, profits most from the tonic and reparative action of mercury. It is hence in these patients that we can look upon mercury as a restoring and augmenting agent of both blood-globules and hæmoglobin. This refers only to the red blood-corpuscles; the white ones were nevertheless counted by Gaillard in each instance. Their number appears to diminish under the influence of mercury, as has also been held as early as 1874 by Wilbouchewitz. [Still it appears hazardous to make any definite statement in this respect. We all know the instability and variance locally and numerically of the white blood-corpuscles. Remembering their abundance in persons affected with even slight suppurations, we would not be surprised to see them decreasing in a woman suffering with vaginitis after the cure of the local trouble.]

The second series of observations refers to the action of mercury on the blood in anæmia. The patient took ordinary doses of either the protoiodide of mercury or of the sublimate. The obtained results are comprised in the following theses:

1. The number of red blood-globules can decrease in anæmic persons under a mercurial treatment in the beginning without re-attaining the original numerical status. More frequently, however, they increase in number progressively up to the fourteenth day, when a slight reduction takes place again.
2. The hæmoglobin increases daily and progressively up to the twenty-fourth day; then it is reduced toward its original figure, but surpassing it still, if the treatment lasts for several weeks.
3. The hæmoglobin increases more con-

siderably in proportion than the red blood-corpuscles. It increases even when the latter diminish in number, so that mercury can be placed alongside of those metals which elaborate hæmoglobin.

4. The bodily weight increases nearly constantly under a mercurial treatment. Still, we are unable to establish an exact relation between this phenomenon and the condition of the blood.

#### THE ELEMENTS OF PROGNOSIS IN BRIGHT'S DISEASE.

At a meeting of the New York Medical Association, held November 16, 1885, DR. AUSTIN FLINT read a paper with this title (*New York Medical Journal*, December 5, 1885). In the popular mind the name Bright's disease at the present time had a prophetic import not unlike that of a verdict of conviction after a trial for life. It was regarded as a hopelessly fatal malady. This prevailing impression reflected the views of the medical profession that a fatal termination would invariably take place sooner or later. This view accorded with our pathological knowledge and clinical experience. But the scope of prognosis was not limited to recovery from the disease. A disease might involve more or less irremediable damage to important organs; but after having progressed to a certain extent the damage might not become greater, and the remaining healthy portion of the organs might be sufficient for all purposes of life and a perfect state of health. Again, a disease might be progressive, but so slow as not to be opposed to long life and general good health. But in chronic disease the danger to health might depend upon associated affections, or chronic disease might be tolerated, provided the conditions were favorable; otherwise it would prove fatal. Was the disease acute or chronic? Assuming the existence of acute Bright's disease, experience taught that, exclusive of the important concomitant affections, it did not end fatally as a rule, and did not result in any permanent renal lesion. In other words, the acute was not followed by the chronic disease, but exceptionally it ended fatally or in the chronic form. In some cases the acute disease was not marked; it continued for some time, and ended in recovery. Here he would substitute for the word acute, subacute. In some cases the question would arise whether the disease was subacute or chronic, and the diagnosis could only be definitely settled in favor of the subacute form by the disappearance of

every evidence of renal disease after some weeks, and the recovery of health.

The author then considered some of the elements of prognosis in cases of chronic Bright's disease. What were some of the conditions requisite for latency? 1. The kidneys must not be damaged beyond a certain degree. 2. The important organs of the body, other than the kidneys, must be capable of performing their respective functions satisfactorily. 3. The laws of health relating to alimentation, exercise, etc., must be observed. Suppose these conditions to be fulfilled, and a lesion of the kidneys to exist which diminished their functional ability one-half, and the disease was not progressive, life and health would be compatible with the existence of chronic Bright's disease for an indefinite period. In order that chronic Bright's disease should be well tolerated, the treatment should relate to accessory conditions required for bringing about toleration, those conditions relating to other organs of the body and to general hygiene. The kidneys in this condition were incapable of meeting an additional demand on their functions. Should the patient fail to observe the accessory conditions mentioned, the inefficiency of the kidneys would become manifest in headache, misty vision, nausea in the morning, impairment of the appetite, and general debility. Examine the urine in such a case, and evidence would be found of chronic Bright's disease which had probably existed for years, the progress of the renal affection at length rendering the organs incapable of performing their functions properly, which caused attention to be directed to the state of the kidneys. It was important, in determining whether the kidneys eliminated excrementitious matters sufficiently not to endanger the health, to make a thorough examination of the urine, not alone with regard to the presence of albumen and casts, but also as to the amount of urine eliminated daily, its specific gravity, and the proportion of the salts. The quantity of the urine might be increased while the specific gravity was so low as to involve great danger from uræmic toxæmia. Suppose the examination of the urine in a case of chronic Bright's disease showed renal adequacy, how should that fact influence the treatment? In this way,—that diuretics, sudorifics, and hydragogue cathartics would not be indicated; indeed, inasmuch as their influence was debilitating and opposed to the accessory conditions for health just mentioned, they were contraindicated. Was the degree of renal

adequacy, as determined by an examination of the urine, reliable in judging of the absence of danger from toxæmia? This question was to be answered in the negative. In some cases of Bright's disease the quantity of the urine was decreased for a long period without serious consequences. The explanation lay in the fact that the excrementitious matter was eliminated vicariously, or its effects upon the system were counteracted by other agents. On the other hand, slight inadequacy, without vicarious elimination and counteracting agents, sometimes led to serious consequences. The prognosis after coma was always grave, yet we meet with cases repeatedly in which life was preserved for a long time. Of acute pulmonary œdema the same might be said as of uræmic coma. In his experience the most serious consequence of Bright's disease was dyspnœa, or renal asthma, apparently due to toxic effects upon the respiratory centre. He had never known such a case to end in recovery, but he had known life to be prolonged for several years after dyspnœa from pulmonary œdema occurring in the course of chronic Bright's disease.

Recapitulating, Dr. Flint said that subacute diffuse nephritis, having the same seat and characters as acute Bright's disease, exclusive of acuteness, occurred not only after scarlet fever and other fevers, but irrespective of these; and when it occurred as a primary affection, or in connection with other diseases, it was liable to be overlooked, or, if recognized, to be mistaken for the chronic form. Further, acute or subacute diffuse nephritis not infrequently occurred as an intercurrent affection in the course of chronic Bright's disease, and rendered the prognosis temporarily more serious. The disappearance of symptoms and the presence of health did not necessarily indicate that the chronic disease was not still in existence. Again, a susceptibility to the causes of inflammation of the uriniferous tubules, irrespective of the existence of chronic Bright's disease, was to be recognized as an individual peculiarity.

#### ON MERCURIAL SOAP.

DR. SCHUSTER, of Aix-la-Chapelle, has prepared some neutral soft mercurial soaps, which we believe to have material advantages over the mercurial ointments. We give the formulas as published in the *Deutsche Medicinal Zeitung* of November 30, 1885.

200 parts of lard are saponified with 100 parts of liq. pot. (caustic), and mixed with 50 parts

of water. 200 grm. of mercury are then rubbed up in the most careful manner with 100 grm. of lard, with the addition of some chloroform, which favors the fine distribution of the metal. We then add from the above soap 300 grm. very gradually, so that the preparation receives the consistency of unguentum hydrarg., and under the magnifying-glass shows no globules of mercury.

Another soap is prepared by taking 1 part each of mercury, lard, and potash-soap, and adding at a moderate heat liq. pot. q. s. until complete saponification results.

The soap is to be placed on the part without any addition of water; then the fingers are to be dipped into water, and the soap rubbed all over the intended region. The great advantages of these soaps over the mercurial salves are that they can be rubbed into the part quicker (in ten to fifteen minutes), do not soil the clothing so much, and very rarely, if ever, produce a mercurial eczema. Besides, a far less quantity of the soap than of the ointment is needed to obtain the same effect, while the absorption of the mercury is claimed to be very prompt and easy. At any rate, the mercurial soaps deserve a trial.

#### POISONING BY CAMPHOR.

MR. J. P. RYAN reports in the *Australian Med. Journal*, October 15, 1885, a case of a young woman who was brought to his house in the afternoon of September 15, her face dusky suffused and perspiring, and breathing slow and shallow, with a tendency to sighing, and her pulse rapid, small, and compressible. Her breath smelt of camphor. She was in a semi-unconscious state, with eyes partly closed, and if placed in the sitting posture her head and body inclined to fall forward and to the side, but if roused and spoken to loudly she made an attempt to sit upright, lifted her eyelids for a moment, smiled in a lackadaisical sort of way, and responded rationally, but in the uniform halting accents of a person laboring under the influence of drink. She was above the middle height, strongly built; and her sister, who accompanied her, stated that she was unusually robust and healthy. They had lunched together at one o'clock on coffee and bread and butter, and afterwards were doing some shopping. She had a slight cold, for which she had been recommended camphor. She had provided herself with a piece as big as an almond, which she began to chew up and swallow in minute portions. Some twenty minutes afterwards she suddenly com-

plained to her sister of feeling giddy and queer, and they had barely time to get into a shop which they were passing when she fell down into a quasi-fainting fit.

Resort was had to the usual restoratives,—fanning, cold water, smelling-salts, etc.,—and after a little she rallied somewhat, but began to talk excitedly, and endeavored to sing or hum snatches of tunes, paying but little heed to the conversation and efforts of those around her. Her face was flushed, the expression peculiar, and her sister said that but for the fact she knew that she never drank any wine or spirits, and that they had been together all the forenoon, she would have come to the conclusion that she was under the influence of drink. As the hilarious excitability was gradually passing into a state of stupor, the sister became alarmed, and had her conveyed to Mr. Ryan's house.

She began eating the camphor at two o'clock. Twenty minutes or so afterwards she had a quasi-fainting attack, followed by hilarity, excitability, with rapidly-ensuing stupor; and when Mr. Ryan saw her, about three o'clock, she was nearly unconscious and in a semi-collapsed state. As her condition was somewhat alarming, no time was lost in giving her an emetic dose, gr. xx of zinc sulphate, which was followed by free vomiting. The vomited matter smelt strongly of camphor, but no pieces of the drug were found in it. After waiting for fifteen minutes, Mr. Ryan gave her 30  $\pi$  of aromatic spirits of ammonia in a small cup of strong black coffee. Her breathing and circulation improved; her face, from being flushed and dusky, had become somewhat pale, the expression being more natural, and she gradually sank into a light slumber. Half an hour afterwards another dose of coffee and ammonia was administered, and by four o'clock she was sufficiently recovered to be removed to her own home. She was somewhat light-headed and giddy, but only complained of a burning pain at the pit of the stomach, which had disappeared by the next day.

The above case is of some interest on account of the severe if not alarming symptoms produced by an apparently small dose of camphor. In most of the text-books on materia medica the ordinary dose is stated to be from gr. i to gr. x, though Wood goes up to gr. xv (*Treatise on Therapeutics*). He affirms that no death in the adult has occurred from the employment of the drug, though he allows that serious symptoms have resulted from poisonous doses, viz., 30 to 60 grs.; and

Sidney Ringer, in his "*Handbook of Therapeutics*," recommends as much as 20 grs. every two or three hours in the delirium of adynamic fevers.

In the case above reported scarcely more than the latter quantity could have been taken; for her sister, a most intelligent woman, assured Mr. Ryan that the piece was no larger than an ordinary almond, such a quantity weighing about 20 grs. If the solubility of camphor in water is borne in mind, it may be fairly assumed that a considerable proportion of this was expelled from the stomach in the vomited matters. Now it follows, if this be granted, that dangerous symptoms of poisoning were produced in a healthy adult woman by a quantity not exceeding the ordinary doses of camphor as given in the principal text-books of materia medica. [It will be noticed that in this case the size of the dose is simply an inference from the statement of the patient, and is therefore open to cavil.—ED. T. G.]

#### FOOD FOR INFANTS AND BREAD FOR DIABETICS.

DR. H. BOEHNKE-REICH describes in the *American Journal of Pharmacy*, December, 1885, a nutritive biscuit and bread which are recommended for infants and diabetics. The nutritive biscuit is intended for infants after they have reached the age of about four months, but is also quite agreeable to adults, and is particularly strengthening to nursing mothers. It is prepared from the best wheat flour, which is mixed with sugar, malt-yeast, table salt, condensed milk, and nutritive salts in such proportions that the finished product has the composition given below. The nutritive salts, according to an assay by B. Kohlmann, made for the Pharmaceutical District Society of Leipzig, contain in 100 parts 6.66 phosphorus, 65.50 oxygen, 5.17 hydrogen, 3.00 carbon, 10.00 calcium, and 9.67 sodium. The dough, properly made, is set aside in a warm place for about an hour and a half, is then placed in suitable moulds, and when sufficiently porous is baked at a dry heat of 200° C. After removal from the oven the cake is exposed to the air for twenty-four hours, and is afterwards slowly roasted at a temperature of 100° C.

The analysis by B. Kohlmann showed a composition in 100 parts of biscuit of moisture 9.76, aliments of respiration 74.94 (including sugar 5.86), plastic aliments (albumen, etc.) 8.56, fat 2.58, inorganic constituents 4.16 (including calcium phosphate 2.25).

Properly preserved, the biscuit remains good for a long time. It has been used by Dr. Furst, of Leipzig, Prof. Deme, of Bern, and many other physicians with good success. The average weight of this nutritive biscuit is not given; but it is stated that two biscuits a day are sufficient for an infant between three and six months old, and four or five biscuits for a child a year old. The biscuit is softened in good warm cow's milk, which, if necessary, is suitably diluted with water, or it may be taken with tea, chocolate, or beef-tea. Dr. Furst states that babies over six months old usually like this biscuit well, digest it properly, and are not subject to glandular swellings, as is often the case if fed on ordinary pastry or farinaceous food.

The bread for diabetics is prepared from pure fresh gluten, with the smallest possible quantity of amylaceous additions. Its odor and taste are pleasant, neither insipid nor sickly, and it may be taken by the patients for a long time without becoming repulsive. Kept in an upright position, it remains palatable for more than three weeks. Kohlmann found its composition to be as follows: Moisture, 22.03; protein compounds, 20.56; fat, 21.78; carbohydrates, 24.28; cellulose, 6.95; mineral constituents (including table salt), 4.40. A similar bread, made by P. Ossian, of Paris, contains a larger percentage of carbohydrates (29.71) and of gluten, the latter being partly replaced by fat in the new bread, which thereby becomes more agreeable for continued use, and retains its softness for a longer time.

#### TREATMENT OF TRIFACIAL NEURALGIA WITH HYPEROSMIC ACID.

Neuber was the first to treat neuralgias with hyperosmic acid. Instead of his watery solution, which has the disadvantage of blackening and of losing its medicinal properties in three or four days, we note that DR. SCHAPIRO (*Archiv. Génér. de Méd.*, November, 1885) has recommended the following mixture:

R. Acidi osmici, 1 part;  
Glycerinæ (chemically pure), 40 parts;  
Aqueæ destill., 60 parts.

He injects 5 drops (containing  $2\frac{1}{2}$  mgrm. of osmic acid) of this solution under the skin. Later the dose is increased to 6 mgrm.

The injections made *loco dolenti* occasion exceptionally an exasperation of the pain by exciting branches of the trifacial which previously were unaffected. According to our author, the specific action of hyperosmic acid

upon the nervous tissues depends primarily upon a cauterization of the nerve-terminations, and secondarily upon the narcotic action of the drug.

He has treated eight patients (five women and three men), all suffering from intense facial neuralgia and having resisted every other treatment, with hyperosmic acid, and experienced only a single failure. In this case some central lesions were undoubtedly at the bottom of the affection. About twelve injections sufficed to bring about a complete cure. These results can be regarded as satisfactory, and certainly invite to a trial of the drug in trifacial neuralgia.

#### THE DIFFERENCE IN THE SYMPTOMS OF STRANGULATED AND OBLIQUE INGUINAL HERNIA.

At a meeting of the New York Medical Society, held November 18, DR. FREDERICK HYDE read a paper with the above title, in which the following were the principal points developed (*Medical News*, November 28, 1885):

1. In proportion to the length of time an inguinal hernia existed would the symptoms and signs of strangulation be mild and chronic.
2. In a case of long-standing inguinal hernia in which signs of stricture of the bowel are obscure, there not being evidence of total obstruction of the canal, often it is not safe to wait for fæcal regurgitation before deciding that strangulation exists.
3. When strangulation occurs at the first protrusion, the symptoms of strangulation will be found to be more marked.
4. If hiccough and fæcal vomiting existed from nearly the beginning of the symptoms, no time is to be lost, herniotomy should be performed at once.
5. If a swelling exists with symptoms of obstruction of the bowel, the patient complaining of severe pain in the abdomen, but of none in the tumor, and had hiccough, although there is absence of marked general disturbance, a fair trial of taxis should be made, and that failing to reduce the tumor, herniotomy should not be delayed. This remark was based on an interesting case, the history of which Dr. Hyde gave in detail. No fæcal vomiting occurred, no pain in the tumor even after taxis, but there was some pain in the abdomen and hiccough. Because of the mildness of the symptoms the consulting physicians delayed the operation more than twelve days, and when it was finally per-

formed, the strangulation was found to have existed within the abdomen. The patient died.

6. If no strangulated portion be found within the external sac, the finger should be passed internally, and adhesions sought for in the neighborhood of the opening.

7. Too long a trial of taxis before dividing a stricture should be guarded against, as it prepares the way for the death of the patient after herniotomy.

8. After stercoraceous vomiting has set in taxis should not be applied, but herniotomy should be performed at once, although the prognosis is unfavorable.

9. If after opening the sac the omentum is found smooth, and no intestine can be detected, the omentum should be opened to learn whether it may not contain a strangulated portion of intestine. It is unfair to speak of herniotomy as a dangerous surgical operation *per se*. The danger attending the operation is due to the condition of the sac and its contents, and to taxis and delay in operating.

DR. J. W. S. GOULEY read some notes on the same subject, in which he reached the following conclusions :

1. When doubt arises in the mind of the surgeon respecting the existence of strangulation of the intestine or omentum in case of incarcerated hernia, it is his duty to give the patient the benefit of the doubt by at once resorting to the operation of herniotomy.

2. Delay in relieving the strangulation is often fatal, while herniotomy in a case in which no strangulation exists is not usually harmful.

3. Medicinal treatment is often delusive, and local applications, such as opium, tobacco-poultices, ice, etc., are in most cases worse than useless.

4. Persistent taxis is infinitely more dangerous than herniotomy, and such taxis, even when it is followed by reduction of the hernial protrusion, is often the cause of fatal peritonitis.

5. Another, though rare, effect of violent taxis is the reduction *en masse* of the hernia in its state of strangulation, and its result is known.

6. As a general rule, two minutes of gentle taxis, the patient being in a hot bath, will settle the question as to the possibility of safely reducing the hernia.

7. Therefore it may be said with propriety that the less taxis, the less ice, the less other topical applications, the less opium, the less

general or special meddlesome interference which often do serious injury to the intestine, the better the chances of recovery in the event of herniotomy. This is particularly the case in femoral hernia.

He said he had abstained from incising the neck of the sac in femoral hernia, but had made divulsion by simply insinuating the index finger through the free opening made in the sac until it entered the abdominal cavity, and had had no trouble in effecting reduction of the intestine, the object of the procedure being to avoid division of the obturator artery should it be abnormally situated. He coincided with Dr. Hyde that hernia is not *per se* a dangerous operation. Dr. Gouley said further that if it seemed necessary in a case of inguinal hernia, after herniotomy, he would open the abdominal cavity in order to relieve the strangulated intestine.

#### THE PREVENTION OF MAMMARY ABSCESS.

In our last issue we referred to the method of prevention of mammary abscess recommended by Dr. Edis, by the use of support by means of a bandage or towel. Dr. Edis appears to have used this method after every delivery, and, by beginning it before lactation was established, with assured success. Occasionally, however, one is called to cases where abscess is on the point of forming, either from neglect or injudicious treatment, and where, consequently, something more is required. Under such circumstances, MR. PHILIP MIALI (*British Med. Journ.*, November 21, 1885) states that he has repeatedly seen all the symptoms of a hot, heavy, inflamed breast, with redness of skin, throbbing and deep-seated pain, pulse being 120 in the minute, all disappear in the course of a few hours under fomentation of hot water and ammonia. An ounce of carbonate of ammonia is dissolved in a pint of boiling water, and when solution is effected the temperature will scarcely be too high for fomentation with cloths dipped in the liquid. These must be assiduously applied for half an hour at least, and repeated for two or three hours if necessary. It is well to protect the nipples, though Mr. Miall states that he has never known them to be injured. Relief is immediate, and more than three applications are seldom required. According to Mr. Miall, unless applied too late or improperly, or some foolish rubbing or drawing with the breast-pump be used, this remedy may be thoroughly relied upon.

### THE ANTIPHLOGISTIC ACTION OF MENTHOL.

DR. SELWYN A. RUSSELL, of Albany, New York, writes to the *Medical Record*, November 21, 1885, to call attention to the use of menthol as an antiphlogistic and anodyne remedy in superficial inflammations, in which, he says, its effects are truly remarkable. "My discovery of its value in such conditions was quite accidental; a patient who was suffering from acute aural perichondritis, failing to obtain relief from the usual anodyne applications, bethought himself of menthol, which he applied by means of the ordinary pencil; the relief from pain was immediate, and from that time, to my surprise, the inflammation quickly subsided. I have since made frequent use of it, and I believe inflammations have aborted which, without it, would have ended in abscess; and in addition the pain, itching, heat, and swelling have been considerably reduced. I have used the ethereal solution (alcohol is also a good solvent) in the strength of from ten to fifty per cent., applying it by means of a camel's-hair pencil. The applications may be made two or three times a day, or more or less frequently according to the indications. A solution in one of the fixed oils may be used on mucous membranes. I have observed the good effects of menthol more especially in boils, carbuncles, excessive inflammation following vaccination, etc. The employment of this substance in superficial neuralgias, for its anodyne effect alone, is often very satisfactory, but its use in this way has been noticed and written upon by others."

### ON THE PROPERTIES AND PREPARATION OF PEPTONE.

The medicine, or rather aliment, called peptone, has of late been so frequently referred to in the medical press, that it is well to gain a clear perception of its properties and method of preparation. We abstract from the *Pharm. Zeit.* of November 25 the following instructive items on peptone:

It is usually assumed that peptones are gained by hydration from albumen, such as egg-albumen, caseine, proteine, and meat-albumen, and that this hydration takes place, if pepsine, pancreatic juice, or papaya-juice, in an acid solution, are made to react on the mentioned albuminous substances. This assumption is all the more justifiable, as peptone can be retransformed into albumen by dehydrating substances. It was believed for

a long time that the latter reaction took place within the human economy until Hofmeister proved experimentally that peptone passes the kidneys unchanged, unless the white blood-corpuscles of the intestinal mucous membrane have appropriated it. According to this author, then, no such retrograde change as formerly believed takes place.

The mode of preparation of peptone is very variable. Some use eggs, some meat, others again milk, while papaya-juice, pepsine, or pancreatic juice are selected by still other manufacturers. It is clear that the preparations of peptone are consequently very different in concentration and physiological action.

The chemical properties of an eligible peptone preparation are as follows:

1. Mixed with at least two parts of water, peptone ought to form a perfectly fluid non-gelatinous liquid.
2. A ten per cent. solution should not grow turbid on the addition of acetic acid, muriatic acid, or ferrocyanide of potassium.
3. On the addition of a solution of picric acid or of tannic acid, yellow flocculi should appear.
4. With sulphate of copper in strong potash solution a violet color should result.

### THE TREATMENT OF HABITUAL CONSTIPATION.

The treatment of constipation is one of the most ordinary, and, at the same time, one of the most important and puzzling problems in clinical practice. It is the common fault of the great proportion of the very numerous remedies in the therapeutic arsenal employed with this object that they either produce too rapid, too violent, or too drastic an effect, that they are weakened in their after-result, and that they will not produce their characteristic effects over any lengthened period of time. The remedies which appear most satisfactory for relieving this condition are the various mineral waters, especially those containing a large percentage of sulphate of magnesium and sulphate of sodium. The natural mineral waters which are familiarly known throughout Germany as "bitter waters," the best known being Pullna, Hunyadi Janos, and Friedrichshall, have already acquired great popularity as efficient aperients, the sole objection which is urged against them being that their activity becomes impaired through continuous use: this defect has, however, recently been shown to be capable of correction

when the mineral waters are combined with the chlorides; and, of all the natural waters, Friedrichshall appears to be the best, as it has been found not to lose its aperient properties through continued use, or even to require an increase of dose. MR. ALFRED S. GUBB reports a number of cases in the *Medical Press*, November 11, 1885, where he has employed it with extremely satisfactory results as a corrective of habitual constipation.

Mr. Gubb administers it in doses of from half a tumbler upwards, taken early in the morning, and combined with an equal proportion of hot water, this being the most effectual method of administering Friedrichshall water for this purpose. He has used it largely for persons of both sexes, and it seemed to be especially advantageous as a mild laxative, exceedingly well fitted for all ordinary cases, and this more particularly for persons of delicate constitution, for women, and for all other persons in whom the object is to produce an aperient effect which should not be drastic or productive of constitutional disturbance. It is often a great object to be able to produce a distinct laxative impression without disturbing the digestion or interfering with the ordinary daily occupation of patients engaged in business pursuits. Here he has found that Friedrichshall water produces its effects by rendering more fluid the intestinal evacuations, and by freeing the intestine of its contents without interfering with the process of digestion or impoverishing the blood. These qualities render it peculiarly suitable for administration to weak or anæmic persons in whom it is important that the laxative employed should not be too concentrated or its influence on the mucous membrane of the intestine too strong.

The mildness of the effect of Friedrichshall water in these cases is, according to Mr. Gubb's observations, well marked. In no case, even after prolonged use, did it prove in any way excessive, and when its use is abandoned for a time, the constipation only recurs gradually when its regulating action on the intestines has given place to the habit of the body or errors in diet which produced the tendency to constipation in the first instance. The non-occurrence of the reactionary constipation which so generally follows the habitual use of aperients is doubtless to be attributed to the large quantity of chlorides present in Friedrichshall water, and to their favorable influence on the progress of digestion and diffusion. In short, the class of cases in which he has found this water of especial

service comprises hemorrhoids accompanied by habitual constipation, hepatic congestion, and in the constipation of pregnancy, which is so often complicated by derangements of the digestion, headache, and dyspnœa. There are many cases of cardiac disease and of cardiac irritability in young people in which it is very serviceable in continuous and diminishing doses. It has long had a high reputation in the treatment of gravel, and for the prophylactic treatment of renal calculi, but of this Mr. Gubb is unable to speak from experience. It has appeared to produce a favorable impression in the numerous cases of strumous and glandular swellings, where we have to contend with a sluggishness of the bowels and of tissue-change generally. Here Friedrichshall water acts as a stimulant as well as an aperient. A certain diuretic effect which is manifested is not uncommonly of service in cases where it is desired to increase the proportion of watery constituents of the urine. It is less adapted to cases of renal disease where our object is to produce copious watery evacuations of a drastic nature, but to lessen venous congestion by gentle and continuous means Friedrichshall water is peculiarly indicated, and is perhaps without a rival.

#### THE TREATMENT OF CHRONIC SPRAINS.

MR. C. W. MANSELL MOULLIN read an interesting paper on the pathology and treatment of chronic sprains at the last annual meeting of the British Association, which contains many points of interest (*British Medical Journal*, November 21, 1885).

Muscular wasting is one of the main and prominent symptoms in chronic sprains which calls for treatment, and is a serious complication to the condition of which muscular debility is the main feature. It tends to perpetuate the trouble, and aggravate it in every way. Fortunately, in galvanism, systematically and regularly applied, there is a powerful ally. Meantime, by means of rest, counter-irritation, pressure, and the use of absorbents, the inflammation can be reduced and the effusion absorbed; and then attempts must be made to restore the muscular system to its normal strength by all the means in our power; orderly and well-regulated exercise, arranged with a view to definite ends, never carried too far, either in extent or time; massage, to improve the circulation; galvanism, to restore the tone; cold bathing, shampooing, and, above all, tonics, fresh air, and

good food. Like most other things, it is easier to prevent than to cure; and, provided due attention be paid and a little watchfulness exercised, there need be no apprehension of this condition supervening, even if growth be as rapid as it often is at the time of puberty. Regular and systematic exercise is all that is required, taking care to avoid sudden violent strains and overfatigue of any special set of muscles.

*ON THE INFLUENCE OF ANTIPYRIN ON THE TISSUE-CHANGES AND ASSIMILATION IN FEVER PATIENTS.*

Antipyrin having undoubtedly secured a prominent place among our antipyretic medicines, it is desirable to study the general influence which the drug exercises on the economy in the state of fever.

DR. WALTER, of St. Petersburg (*Wratsch*, No. 30, 1885), gave antipyrin to four fever-patients (pleuro-pneumonia, pleuritis, typhoid fever, and tuberculosis) in doses of 3 to 8 grms. (45 to 120 grs.) *pro die* without observing any unpleasant after-effects, except some nausea and sweating. On heart and brain no noticeable impression was made by the drug; but alongside of the reduction of the febrile temperature Walter observed also a reduction in the nitrogenous tissue-changes, and ascertained, likewise, that the assimilation of proteids was materially favored by the drug.

We regret to have at present no details yet of these interesting investigations.

*RECURRENT LARYNGITIS AND OBSTRUCTION OF THE NARES.*

DR. E. FLETCHER INGALS read a paper before the Illinois State Medical Society on the above subject, of which the following are the conclusions (*Journal of the American Medical Association*, December 5, 1885):

1. Recurrent laryngitis is usually dependent upon obstruction of the nasal cavities.
2. This obstruction, in the majority of cases, is caused either by deflection and thickening of the septum, or by what is known as hypertrophic catarrh.
3. To effect a permanent cure the obstruction must be removed.
4. The operative procedures necessary for the removal of these obstructions may be made painless by the use of hydrochlorate of cocaine.
5. This method of treatment, properly carried out, may be relied on to cure the catarrh and the laryngitis which it has caused.

6. Great improvement in the general health often results from the removal of the nasal obstruction.

7. In acute colds or exacerbations of hypertrophic catarrh, immediate relief may be obtained by the insufflation as often as needed of small quantities of cocaine.

*THE APPLICATION OF ACUPUNCTURE TO THE TREATMENT OF CERTAIN FORMS OF CHRONIC RHEUMATISM.*

DR. G. LORIMER, in a paper with the above title read before the Section of Medicine at the last meeting of the British Medical Association in Cardiff (*British Med. Journ.*, November 21, 1885), calls attention to a mode of treatment of chronic rheumatism which at one time seemed to enjoy considerable popularity, but which has latterly fallen into disuse. Dr. Lorimer thinks that in this method we have a very valuable mode of treatment, and he reports twelve cases of various forms of chronic rheumatism, in nearly all of which improvement and freedom from pain resulted. Dr. Lorimer summarizes as follows the results at which an extensive experience in its use has led him to arrive:

In chronic rheumatism of the muscles and their fasciæ and aponeuroses, there are usually three conditions present: 1, pain; 2, impaired mobility or muscular disability; and, 3, impaired nutrition, leading to muscular atrophy. The last condition is not always present, and is most marked in cases of a pronouncedly chronic character. The first two conditions may occur separately or conjointly. They may coexist in equal degree, or they may occur each in greater or less degree.

Acupuncture may be employed with advantage for the relief of pain for the removal of muscular disability; and, with the removal of the latter condition, muscular atrophy is usually improved. Acupuncture, however, is less certain and efficacious in the relief of pain than in the treatment of muscular disability. For the relief of the latter condition, however, as well as sometimes for the former in rheumatism of the lumbar muscles, of the muscles of the thigh, and of the muscles of the arm and shoulder, the effects are sometimes signally efficacious.

With regard to the last-mentioned situation (namely, the shoulder), the relief from muscular disability is most marked when the disablement is referred to a point situated in the central or lower part of the deltoid muscle.

When situated in the upper part relief is less frequent, and when above the scapular spine it is very seldom obtained. The certainty of relief is in proportion to the limited area of obstruction to movement; if, however, the area of obstruction to movement be extended and indefinite, success is less likely to result. In some cases galvano-puncture succeeds when acupuncture fails.

After the removal of the needle at the seat of puncture there frequently appears a red areola, from half an inch to two inches in diameter. The appearance of this areola bears a direct relation to the success of the operation. It is generally absent in cases where the action is inert, and the result negative.

In the removal of muscular disability the action of acupuncture is immediate. The maximum amount of muscular power, however, obtained from its application is gradual, being from ten minutes to one hour after the removal of the needle.

It is doubtful if any benefit is obtained from retaining a needle beyond two minutes in the treatment of cases of muscular disability. More benefit is obtained from increasing the number of needles than prolonging the time of their insertion. With regard to relief from pain, however, the converse is true.

When extensive muscular atrophy is present, relief is doubtful. When the latter condition is present, and is an obstacle to improvement, galvano-puncture may succeed after acupuncture has failed. For the relief of pain several applications may be required, each of some hours' duration. Cases which most frequently receive benefit in relief from pain are those of subacute inflammation of fibrous tissue, myalgia, and anomalous forms of rheumatism, which sometimes attack the surrounding structures of articulations subsequent to injury. In some instances, after the application of acupuncture-needles, pain may be removed, but it may pass to the corresponding situation on the opposite side of the body.

After the application of the needle there is generally experienced, at the point of insertion, and for some distance from it, a feeling of coldness or numbness, or a sense of prickling or heat. Syncope seldom occurs from the employment of acupuncture.

Acupuncture is less frequently followed with beneficial results in muscular disability, and muscular atrophy consequent on sciatica.

The needles employed are about two inches in length, or longer. They are set in round

handles, and should be introduced with a gentle rotary motion.

#### *TUBERCULAR MENINGITIS CURED BY IODOFORM.*

A Swedish physician, DR. EMIL NILSSON, alleges that he has cured an undoubted case of tubercular meningitis by frictions on the shaved scalp with iodoform ointment (1 to 10). The patient was a boy, aged 8, whose mother had a family history of phthisis, and four of whose brothers and sisters had died from tubercular meningitis. The symptoms in this child's case were similar to theirs,—headache, torpor, convulsions, strabismus, and pyrexia. He was at first treated with calomel and iodide of potassium, but did not improve; and, after having been under treatment a week, became distinctly worse, being unable to take food or medicine. The pallor of the face, which had pre-existed, gave way to flushes of the cheeks. The child threw himself out of bed, and presented several clonic spasms of the limbs and of the facial muscles. The head was then shaved, and iodoform ointment rubbed in, an oil-skin cap being put on. The friction was repeated three or four times in the day, and the next day there was a decrease in the convulsive movements, the sleep was calmer, and the spasmodic contractions, which had previously been excited by the slightest noise, now ceased to be so. Consciousness shortly afterwards returned, and the child's face became of a more natural color. This, however, was accompanied with a severe coryza, redness of the lips, and an irritable cough, the breath smelling strongly of iodoform. The ointment was discontinued, and syrup of iodide of iron given. The unpleasant symptoms rapidly disappeared, and the child was soon running about in good health.

#### *HEMORRHAGIC AMBLYOPIA CURED BY DILATATION OF THE SPHINCTER ANI.*

The following case seems to well illustrate two points: first, the serious amount of amblyopia liable to be produced by frequently-recurring hemorrhages extending over a long period of time; and, second, the value of the surgical procedure of free dilatation of the sphincter ani under ether. MR. ROBERT N. HARTLEY (*Med. Times and Gazette*, November 28, 1885) was consulted by a man who was gradually losing his eyesight, the distant vision of each eye being only equal to twenty-seventieths, while no type smaller than 14

Jäger could be read. There was nothing, however, in the appearance of the eyes to account for so much defect except a slight pallor of the disks. Questioning elicited the fact that for ten years he had suffered from repeated bleedings from the anus, and the bowels were never moved without great pain, and seldom without bleeding, sometimes slight, often profuse, and for the last three months he had frequently to leave his work and go home on account of severe bleeding. He was constantly taking either purgatives or astringents, and the introduction of the finger into the bowels caused such intense pain that a thorough examination was impossible without an anæsthetic. A few days later he was put under ether, and Mr. Hartley found an enormously powerful sphincter ani, the internal fibres being especially marked as rigid rings extending for some distance up the bowels. Mr. Hartley freely and thoroughly stretched, with the fore and middle fingers of each hand, the rigid sphincter until all signs of resistance had ceased and all the fingers of one hand, in the form of a cone, could be easily pushed into the rectum. The congested and swollen mucous membrane now protruded, and the surface of it was seen to be here and there marked by ulcerated patches, which had been no doubt the chief source of the hemorrhage. Nothing more was done except the swabbing of the parts with carbolized glycerin. After three days' rest in bed the bowels moved spontaneously for the first time with little or no pain and no bleeding, and six weeks afterwards he reported that he had never bled once since the operation, had never taken a dose of medicine, that his bowels acted every morning without pain or difficulty, and that his sight was perfectly normal.

#### *ELECTRICITY AS A THERAPEUTIC AGENT IN GYNÆCOLOGY.*

From an elaborate study of the value of electricity as a therapeutic agent in gynæcology, DR. PAUL F. MUNDÉ draws the following conclusions (*American Journal of Obstetrics*, December, 1885) :

1. Electricity locally applied is a valuable agent in gynæcological practice, and should be more widely used than it is.
2. It does not require special knowledge or experience as an electrologist to be able to use the agent safely and beneficially in gynæcological practice.

3. The remedy, if properly used and on correct indications, cannot do harm.

4. It should be used only in chronic conditions, and if it is the galvanic current, should give no pain.

5. The conditions in which the faradic current is indicated are chiefly those characterized by deficient development or want of tone of the sexual organs, such as imperfect development of uterus and ovaries, superinvolution, subinvolution, amenorrhœa, uterine displacements, interstitial fibroids. The object of the faradic current is to stimulate the organs to increased growth or activity, and to produce muscular contraction.

6. The conditions in which the galvanic current is indicated are those in which it is desired to promote absorption of adventitious products, chiefly the result of previous inflammation, to allay pain, to excite reparative action, and occasionally to act as a caustic. The rapidly-interrupted galvanic current, however, also excites muscular contraction.

7. Perseverance in the treatment is essential to success.

8. Acute and subacute inflammatory conditions, as a rule, counterindicate local treatment by electricity.

9. The pathological conditions in which electricity proves useful are those in which other treatment often fails, or cannot be borne by the patient.

10. In organic diseases, a permanent cure, or a restoration of the diseased organs to perfect health, can usually not be accomplished by electricity ; but great relief from pain, and certainly temporary improvement in otherwise intractable cases, can be achieved by it without danger, and with comparatively little discomfort to the patient.

#### *THE OLD AND NEW TREATMENT OF CORYZA.*

In the *Deutsche Medic. Zeitung* of November 30, 1885, we find an interesting letter of DR. KRAKAUER, of Berlin, on the treatment of coryza, embracing his experience on himself and a number of patients.

This physician was affected with a chronic rhinopharyngitis, which showed a violent exacerbation every two or three months. Two minute doses of belladonna, taken in intervals of four hours, always succeeded in checking the highly inconvenient secretion of the nose (which was strong and copious enough to produce an eczema of the nares and upper

lip), but did not in any way abort or shorten the coryzic process itself. The nose remained as stopped up as before.

With cocaine, however, Krakauer obtained much more satisfactory results. As soon as the exacerbation was noticed to set in (sensations of tightness and itching in the nose, and inclination to frequent sneezing), he inserted into each aperture of the nose a tampon three to four cm. long, saturated with a five to ten per cent. solution of cocaine. In every instance all the mentioned symptoms were invariably suppressed, and the coryza itself prevented from actually setting in. The tampon was allowed to remain *in situ* for four to five hours, and no further medication was needed.

The same procedure has since proven a success in a number of coryza cases that came under the observation of Dr. Krakauer. Applications of tampons saturated with a ten per cent. solution of menthol were found to give equally satisfactory results in coryza. Both applications deserve to be borne in mind.

#### THE PRESENT STATE OF THE ERGOT QUESTION.

DR. RUDOLPH KOBERT publishes in the *Practitioner* (December, 1885) the following summary of the results of his investigations as to the influence of the different constituents of ergot upon the pregnant uterus:

**Ergotinic Acid.**—Dr. Kobert has administered this substance and its sodium salt internally and hypodermically to pregnant bitches, rabbits, cats, and sheep. The doses given were at first small, and then increased, until finally they were toxic. The result of all these experiments entirely agreed with his former ones. When administered internally, even the largest doses are well borne, without the supervention of uterine contractions and without any material disturbance of the mother. At most the stools become semi-fluid. When injected subcutaneously, relatively large doses cause complete narcosis, lasting twenty-four to forty-eight hours, during which reflex action ceases. Nevertheless, neither contraction of the uterus nor expulsion of the young occurs.

After very large doses the blood-pressure falls very low, and, as a consequence, the young die, but are not expelled.

From these experiments it will be seen that ergot of rye does not owe its ebolic power to the ergotinic acid contained in it, and that we may consider as clinically worthless all preparations of ergotinic acid and of sclerotinic

acid (so called) and all aqueous extracts which do not contain these principles which are soluble in alcohol. Hence it follows that the extractum secalis cornuti of the *Pharmacopœia Germanica*, Editio II., is worthless.

**Cornutine.**—This substance is now prepared and supplied commercially by Gehe & Co., Dresden, and is not to be confounded with the very different ergotinine of Tanret. The latter is quite inert. The former, however, produces uterine contractions both in animals which are pregnant and in those which are not pregnant, but with this difference, that in the latter the contractions are accompanied by coincident vomiting, diarrhoea, salivation, and irregularity of the pulse; but in the former the irritability of the uterus is much increased, and, as a consequence, the uterine movements come on after doses so small that no other symptoms at all appear. Consequently, it was always possible, in dogs and cats, to bring about the expulsion of the foetus without seriously jeopardizing the life of the mother, when the cornutine was injected subcutaneously. It was a matter of no consequence whether the young were mature or not. The amount necessary to this result was less than an eighth of a grain. Gehe's preparation not being as yet a chemically pure one, must be administered in larger doses.

**Sphacelinic Acid.**—This is a resinous body, insoluble in water, and consequently must be administered by mouth in the form of an emulsion. In dogs and cats a sufficient dose never failed to evoke powerful labor-pains in the pregnant uterus, followed rapidly by the birth of the foetus; yet, not one of the mother-animals lost her life in consequence. The contractions after this substance Dr. Kobert describes as being tonic, and after the cornutine as being clonic.

From the foregoing it will be seen that in the ebolic action caused by ergot both cornutine and sphacelinic acid take part.

Dr. Kobert states that cornutine acts by influencing directly the centre for the uterine contractions situated in the spinal cord; but sphacelinic acid acts directly upon the uterus itself. And the combined action of these two substances is necessary if it is wished to produce the action of ergot upon the uterus and yet avoid any other untoward effects. Therefore the only rational preparation for use in cases of parturition is one which contains all the cornutine and sphacelinic acid but no ergotinic acid, for the latter is very injurious to the stomach and has no influence upon the

uterus. Such a preparation, when administered internally, was, when fresh, exceedingly active, producing abortion with absolute certainty in pregnant animals. In the form of pills, it has been employed with success in man to stop hemorrhages in various organs, and also in the treatment of vascular dilatation in cutaneous diseases. Unfortunately, it does not keep well for more than six months, and must each year be prepared afresh. A preparation a year old is almost absolutely worthless. It is necessary to state that neither ergot itself, nor any of the numerous commercial and European and American preparations which Dr. Kobert has examined, have retained their therapeutic powers for more than twelve months. Of course the ergotinic acid remains unaffected, but this is valueless.

The preparation of an active extract depends upon the solubility of cornutine and sphacelinic acid in absolute alcohol, in which latter ergotinic acid is insoluble.

It is only necessary to bruise well the fresh ergot, and to exhaust thoroughly with the strongest alcohol. After evaporation of the alcohol at a low temperature, there remains a residue, consisting of the inert fatty oil, and the whole of the cornutine and sphacelinic acid. A portion of the oil may be previously got rid of by extracting with ether, but at the sacrifice of a small amount of the active substances. The extract thus prepared is not well suited for subcutaneous injection. The dose cannot be foretold, because the proportion of active principles present in ergot varies exceedingly with the year and the district.

As the extract of ergot is usually prepared in November, it is to be hoped that this article will be of the greater utility.

#### CONVALLARIA MULTIFLORA IN HEMORRHOIDS.

DR. J. W. HAMER (*Columbus Med. Journ.*, December, 1885) has used a decoction of the root of convallaria multiflora with considerable success in the internal treatment of patients suffering from piles. His method of administration was to boil one or two ounces of the root in a pint of sweet milk, to be drunk in the course of a few hours, taking about two ounces at a time, a fresh decoction being made every day. Dr. Hamer reports six cases, in four of which great relief was obtained, while in the other two no fair test was given the drug. He finds that it acts best in those persons who have a sluggish

condition of the portal system and have frequent bilious attacks. He believes that it does not cure hemorrhoids by relieving the patient of constipation, for where constipation was found it still existed after the patients were cured, but that it acts by restoring tone to the flaccid condition of the hemorrhoidal veins. The drug should be used for at least one week before stopping its use, and the fresh root should be employed in all cases, as by long drying it appears to become inert.

#### PURE TEREbene IN THE TREATMENT OF WINTER COUGH.

DR. WILLIAM MURRELL states, in the *British Med. Journ.*, December 12, 1885, that he has notes of one hundred and fourteen cases of winter cough which were all treated with pure terebene, a substance prepared by the action of sulphuric acid and oil of turpentine. He states that it is an agreeable remedy, being a clear, colorless liquid, with an odor like that of fresh-sawn pine wood. It will not mix with water, but as the dose is small it can readily be given on sugar. This must not be confounded with the patent medicine sold under the name of terebene. The best method of indicating the sphere of action of this drug and of illustrating its utility will be to give a brief abstract of the notes of one of Dr. Murrell's cases.

R. N., aged 43, a commercial traveller, stated that he had been subject to cough every winter for twelve years. His work was against him, and he was a good deal exposed to wet and cold and the inclemency of the weather. His cough used to trouble him badly only in the winter, but year by year it seemed to be coming on earlier, and now he was hardly ever free from it. It came on in fits, which shook him to pieces, and it was always very bad the first thing in the morning, often making him retch and vomit. There was a great deal of phlegm, thick and yellow, when he was in the country, but speckled all over with black in London. It was difficult to get up, unless he could get some hot tea or something to loosen it. The shortness of breath was worse than all, for it prevented him from going about, and interfered with his business. He had never spat any blood worth speaking of, but there were at times streaks after a severe bout of coughing. He became no thinner, generally losing a little in the winter, and picking up again in the summer. He had had a great deal of treatment, and mixtures, lozenges, and liniments

without end. On examining the chest, it was found to be emphysematous, and there was a loud bubbling rhonchus at the base of each lung. On November 1 he was ordered 10 drops of pure terebene on a piece of sugar every four hours. In three days he returned, and said there had been a marked improvement; the cough was easier, the phlegm was lighter in color and not so thick, and the breathing was decidedly better. The dose was increased to 20 minims every four hours, and a week later the patient wrote to say that he was better than he had been for years, and was almost able to do without the medicine. Dr. Murrell saw nothing of him again until January 6, when, being in town, he came to see him. There had been some return of the old symptoms, and he was anxious for further treatment. Dr. Murrell ordered him a small Maw's spray-diffuser, holding about an ounce, and instructed him to use it with the terebene, as an inhalation, several times a day. A fortnight later he wrote, saying that he had bought a larger apparatus, and that his complaint was more amenable to treatment than it had ever been before. The terebene-spray eased the cough, brought up the phlegm, and, above all, relieved the shortness of breath. On his long railway-journeys, when he was unable to use the spray without inconveniencing his fellow-passengers, he rubbed the terebene on his moustache and beard, so that it might slowly diffuse, and, as he said, "softened the atmosphere."

One of the great advantages of pure terebene is that it is not a bulky medicine. An ounce bottle, carried in the pocket, will last for days, and is always ready for use. It is best to begin with 5 or 6 drops on sugar every four hours, and gradually to increase the dose to 20 minims. This is, for most people, the maximum quantity, but the drug has little or no toxic action, and one patient was so enraptured with his remedy that he insisted on taking a teaspoonful every four hours for a week. The only disadvantage Dr. Murrell has ever noticed from its employment is that it gives a peculiar and characteristic odor to the urine, a circumstance which patients never fail to mention. When used as a spray, from 1 to 2 ounces should be diffused and inhaled every week. In some instances he has tried giving it mixed with an equal quantity of olive oil, flavored with oil of peppermint. In twenty-five cases he has given the terebene in the form of an emulsion, made by mixing it with a little tragacanth powder, adding water and shaking well. Each ounce of the emul-

sion contained a drachm of the terebene, and it was usually given in  $\frac{1}{2}$ -ounce doses, four times a day. The results were excellent, but not better than with the simple terebene itself, and he saw no reason for continuing the use of a more expensive preparation. In every case of winter cough in which the terebene-spray was used systematically there was a marked improvement. In many instances it was noticed almost immediately, but in other cases, especially the very chronic ones, the patient had to continue using his remedy for some weeks. Even when there was marked emphysema, with little movement of the chest-walls, some benefit was experienced. He treated eighteen cases of phthisis by the same method, and the results were certainly most encouraging. It did most good when there was old consolidation, when no active mischief was in progress, and especially when there was no elevation of temperature. He has also used it as a dry antiseptic inhalation on the cotton-wool of a respirator in phthisis, and has been much pleased with the results. In one case, that of a young lady, the respirator was worn almost continuously night and day for nine months; and the right lung, which was breaking down, cleared up, the temperature becoming normal, and the cough and other symptoms subsiding. Dr. Murrell thinks that terebene may be useful in checking hemorrhage from the lungs, but has no data to offer.

Many sufferers from winter cough also complain of acidity and flatulence. He soon found that the internal administration of pure terebene was an excellent remedy for this combination of symptoms. It checks the formation of flatus so quickly, and is so efficacious in expelling any that may remain in the stomach or intestines, that he constantly employs it in cases of dyspepsia when flatulence is a prominent symptom. Patients like it, and often continue taking it for months or years. It acts as an antiseptic, probably in much the same way as glycerin, oil of cajuput, and oil of eucalyptus. He evinces surprise that it has not come more largely into use in the treatment of flatulence.

Pure terebene is of such value in winter cough that he rarely resorts to other remedies. This year, however, he has tried a combination consisting of equal parts of pure terebene, oil of cubebs, and oil of sandal wood, mixed with liquid vaseline. This he uses in an atomizing apparatus invented by Mr. W. F. Semple, of Ohio, an apparatus which is somewhat complex and difficult of descrip-

tion, but may be said to consist essentially of a jar in which the medicated fluid is finely atomized by a blast of air propelled by a rubber ball. A nose-tube is attached, and the fine spray is inhaled either through the mouth or nostrils. It is certainly one of the best forms of spray-apparatus ever invented, and, when used with a cocaine solution, will be found wonderfully efficacious in the treatment of hay-fever and coryza. The formula Dr. Murrell has given yields excellent results, not only in winter cough, but also in post-nasal catarrh. He has made some observations on this point, in conjunction with a well-known tenor, and has been astonished to note what a marvellous difference there is in the tone of his singing-voice after using it for only a few minutes. It is a powerful expectorant, and, if inhaled the first thing in the morning, when the mucous membranes are covered with thick, viscid secretion, will give very great relief. Pure terebene is a valuable remedy, and will in time come largely into use.

#### *SUPPURATION AROUND THE VERMIFORM APPENDIX TREATED BY ABDOMINAL INCISION.*

At the meeting of the Clinical Society of London held December 11, 1885, Dr. THOMAS BARLOW and Mr. R. J. GODLEE (*Med. Times and Gazette*, December 19, 1885) read a paper relating to a man, aged 20, whose previous history was unimportant, except that for the last two years he had been subject to attacks of diarrhoea and vomiting. His illness began rather acutely on September 12, 1885, with loss of appetite, severe abdominal pain, and, later, vomiting and absolute constipation. He was admitted into University College Hospital on the 15th, with a temperature of 102.4°, intense abdominal pain and tenderness, intermittent bilious (not stercoraceous) vomiting, and tight distention of the abdomen. There was a small patch of slight redness in the right iliac fossa. The diagnosis appeared to be between mischief about the appendix and constriction of the intestine by a band high up. He was given opium and iced beef-tea, and ice was applied to the abdomen. The temperature fell to normal, and the pulse was about 90, full and soft, the tongue dry, and the color good; but, as the symptoms were unrelieved, an exploratory incision was made in the middle line on the night of the 16th. General early peritonitis was found, but lymph only in the neighborhood of the cæcum, surrounding a collection

of fetid pus. The vermiform appendix was much thickened. A second incision was made over the right iliac fossa, and a large drainage-tube was inserted through it, reaching down to the appendix, a smaller one being placed in the median incision, which was closed with sutures. The peritoneum was first washed out with a solution of corrosive sublimate (1 to 500). The patient made an excellent recovery, the temperature remaining normal, and the pulse about 90. He was fed principally by the bowel for some time; beef-tea and arrowroot were allowed on the twentieth day, and minced meat a fortnight later. No drugs were given except morphine for the first two days. Thirst was allayed by means of warm-water enemata. He had slight albuminuria a day or two after the operation, and a little later a parotid bubo occurred, which did not suppurate. It was claimed that the uncertainty of the diagnosis justified the exploration, and that the early evacuation of the putrid pus rescued the patient from a condition of very great danger, and prevented the matting together of the intestines, which would otherwise have occurred. The freedom with which the peritoneum might be treated was pointed out, and the advisability of withholding food from the stomach for a prolonged period in such cases was insisted upon. Remarks were also made upon the absence of peritonitis and the presence of albuminuria as points in the diagnosis, and upon the relation between inflammation of the parotid and diseased states of the peritoneum.

#### *THE PHYSIOLOGICAL ACTION OF GRINDELIA ROBUSTA.*

Dr. JOHN A. BUFFINGTON arrives at the following conclusions in a graduation thesis as to the physiological action of *Grindelia robusta* (*American Journ. Med. Sci.*, January, 1886): *Grindelia* was found to be not actively toxic. The lethal dose of the fluid extract, the preparation used in the experiments, was 3ii to 3iii for rabbits weighing twenty-eight ounces to thirty-two ounces, and ʒx to ʒxv for frogs weighing one ounce; and the time required to cause death was one to three hours in the former, and half to one hour in the latter.

*Grindelia* first lessens, then destroys sensibility, the action beginning in the peripheral end-organs, then involving the trunk of the nerves, and ultimately the spinal cord. Motility is affected in the same order, the paraly-

sis beginning in the nerve-terminals, then involving the nerve-trunks, and finally the motor centres in the spinal cord.

The heart is slowed because of an increase of inhibition, due to stimulation of the cardiac inhibiting centre, and the blood-pressure is raised, chiefly by stimulation of the vaso-motor centre in the medulla. The respiration is increased in frequency by an action of the agent on the respiratory centre, and also on the terminals of the pneumogastric in the lungs. Toward the end the respiration becomes slower, and is jerky in character, and death ensues by arrest of respiration, the heart continuing its action some time longer.

The cerebral effects of grindelia are quite pronounced. A condition of narcosis, more or less profound, ensues as the effects of the drug develop. This action appears to be due to a direct impression made on the cells of the cerebral lobes.

A marked increase of the urinary secretion was noted in all the animals experimented on. As some constituents of the drug appear in the urine (the resin?), a direct action on the renal structure may be admitted. The increase in the blood-pressure is another factor, and, it may be, the chief one.

This investigation throws light on the nature of the curative effects exerted by grindelia in asthma, for the relief of which hitherto it has been chiefly used. The cerebral, the cardiac, and the renal actions, however, suggest its use in other maladies.

PRACTICAL SURGERY, INCLUDING SURGICAL DRESSINGS, BANDAGING, FRACTURES, DISLOCATIONS, LIGATURE OF ARTERIES, AMPUTATIONS, AND EXCISIONS OF BONES AND JOINTS. By J. Ewing Mears, M.D. Second Edition.

Philadelphia: P. Blakiston, Son & Co.

The propriety of writing condensed and brief descriptions of surgical affections and their treatment has always been a questionable proceeding with us; but every now and then a work, the merits of which are undeniable, is placed in our hands, and we are compelled to grant its author the praise due him. To this class we would assign the work of Dr. Mears. Our author has not attempted too much. He has limited himself to the above-named subjects; and his work, while concise, is not slighted, so that the book cannot fail to aid the student in acquiring a knowledge of the subjects which it treats. Indeed, the busy

practitioner may with benefit turn for information to its pages.

Part I. considers "*Surgical Dressings.*" This most important element in the successful results of treatment in all surgical operations cannot be too urgently insisted upon; and all information relating to the subject ought to be sought after by the surgeon. Dr. Mears has given us a very full section upon the various means we may employ and their methods of application. Antiseptic dressing of wounds has, as it should, been well and minutely dwelt upon. Full directions in the application of Lister's dressing, and also modifications of the same, are given. The various agents that have been employed and advocated by different surgeons, in order to assist in the healing of wounds, and the method of preparing them, are given. We are glad to see our author calls attention to the means of drainage introduced by Mr. Chiene, who employs catgut arranged in a special manner, which we regard as one of the best, if not the best, method of drainage yet devised. The buried suture introduced into surgery to obviate the employment of any drainage substance whatever is a method of dressing which we can, from our personal knowledge of its use, speak most favorably of, and regret Dr. Mears has not given a description of its application.

Part II. treats of "*Bandaging,*" in which the methods of applying the *roller*, *Mayor's system of handkerchief dressings*, and *immovable bandages* are fully described. The cuts illustrating the manner of applying the different bandages are numerous, and will be found to greatly aid in comprehending this very important part of the treatment of surgical lesions.

Part III. discusses "*Fractures.*" This section is an addition to the present edition; and while it is, in our opinion, too brief to do justice to this very important division of surgery, yet we have been quite favorably impressed with the arrangement and the writer's descriptions and treatment of these lesions. The part which treats of fractures in general, their cause, symptoms, diagnosis, prognosis, and treatment, appears to us particularly good, and gives evidence of the author's practical experience and acute observation. The advice given under special fractures for their treatment may safely be followed. In fractures of the skull we think it would have been a valuable addition if a more detailed account of the indications for performing the operation of trephining had been included

under these lesions. The transfixing of the nasal bones in cases of their fracture by means of a pin, as advised by Mason, is a most simple and very efficient method of treatment, and far more comfortable for the patient than the means recommended by our author, of pieces of catheter or waxed sponges introduced into the nasal cavity. In the treatment of fracture of the patella Dr. Mears has given us the various methods which are generally employed, but has omitted the more recent treatment introduced by Lister, and now advocated by other surgeons, who have adopted it with unusual results. We refer to cutting down upon the fragments, and wiring them together under strict antiseptic precautions.

Part IV., on "*Dislocations*," is also a new section to this edition. It includes everything of any importance in relation to these lesions. The author's view in regard to the reduction of dislocations is one in which we fully agree. He says, "The success which has attended the employment of manipulation in effecting reduction of recent and also of old dislocations justifies the belief that their [mechanical appliances] application is not necessary in any form."

Part V. treats of the "*Ligation of Arteries*." It is abundantly illustrated, and contains very concise and comprehensive descriptions of the various procedures for performing these operations.

Part VI. describes "*Amputations*," in which the different operations suitable for the various regions are given. Hemorrhage and the means for its control receives due attention. The after-treatment in amputations, and upon which, in a great measure, depends success or failure, is quite full and explicit; but we have become so thoroughly convinced of the great advantages, both to surgeon and patient, by the employment of antiseptic dressings in this particular variety of surgical operations, that we regret Dr. Mears has not more emphatically insisted upon their employment in every case.

Part VII., the concluding section of the book, on "*Excisions of Bones and Joints*," is a most valuable addition to the present edition. The introduction of antiseptic dressings into surgery has gradually caused surgeons to regard excisions with much more favor than they formerly did, and their adoption in suitable cases has no doubt been the means of saving many useful limbs which would previously have been sacrificed.

In concluding our notice of the above work

we congratulate its author upon having very ably and satisfactorily performed his task, and we are confident that students, for whom the book has been more especially written, will receive valuable assistance from a study of its contents.

A REFERENCE HANDBOOK OF THE MEDICAL SCIENCES, embracing the Entire Range of Scientific and Practical Medicine. By various writers. Illustrated by chromolithographs and fine wood engravings. Edited by Albert H. Buck, M.D., New York City. Volume i. New York: William Wood & Company, 56 and 58 Lafayette Place, 1885.

The enterprise or the spirit of excessive competition which now prevails among American publishers is yielding a most extraordinary crop of great books. Possibly the spirit which has been aroused by the laboriousness of Dr. Billings in the surgeon-general's office at Washington is becoming epidemic. The latest victim either of this contagiousness or of the publisher's zeal is Dr. Albert H. Buck, of New York City, if indeed his present attack ought not rather to be considered of the nature of a relapse than of an original affection. As the result we find upon our table the quarto volume which is to be followed, we are told, by six volumes like itself.

We have in the title of this volume a further instance of the misuse of the English language, which seems to have come upon us from the German. The work is called a Reference Handbook, when it is really a large and elaborate encyclopædia, containing in the whole of its volumes nearly six thousand double-columned pages of very close, small type.

The illustrations are very numerous. Most of those in the type are judiciously selected, and really add to the value of the work. The chromolithographs in the present volume are four in number. The first is a handsome plate of the *Arnica montana*, which we suppose has been added for æsthetic purposes. The second represents the blood spectra, and really has a scientific and practical value. The third, being representations of cerebral hemorrhage, we suppose owes its existence to the fondness which is believed to exist among so many Americans for bright red colors; whilst the fourth (types of carcinoma) is well calculated to strike awe, and thereby inspire respect in the hearts of the laity. The articles are written by a number of contributors, and seem to us uniformly good. Some of them are of very great merit. As an example we should mention the article by Dr. Henry upon blood. The chief value of this book to most

of us will be found in the information contained on matters concerning which knowledge is not easily accessible. As an instance of this we may cite the excellent *résumé* of the subject of Army Field Medical Organization, by Surgeon Charles Smart. We know of no book ordinarily to be found in a physician's library which contains so numerous, and usually so satisfactory, accounts of various watering-places and sanitary resorts, as does this one. Thus, in regard to Asheville, North Carolina, we find nearly three pages of condensed information. Concerning Biarritz we have two pages. Full information is given about all the health-resorts for which we have looked, except the Arkansas Hot Springs, and probably a description of this will be found in a future volume, under the head of "Hot Springs" of Arkansas. There is therefore much freshness about this volume, and we trust that it will make itself a home in American literature. We congratulate Dr. Buck upon the wisdom which he has displayed in selecting his contributors, and the success which he has thereby obtained.

**THE PRACTICE OF PHARMACY.** A Hand-book for Pharmacists and Physicians, and a Text-book for Students. By Joseph P. Remington, Ph.G. With nearly five hundred illustrations.

Philadelphia: J. B. Lippincott Company. London: 15 Russell Street, Covent Garden, 1885.

Professor Remington is a very well known man, whose great success as a teacher and as a pharmaceutical editor of the United States Dispensary has given him a position second to no one in pharmacy in the United States, and, indeed, we may say, in the world. When, therefore, it was rumored that he was preparing a general work upon pharmacy, to fill the general vacancy left by the decrepit state into which Parrish's Pharmacy had fallen by old age, much was hoped for, and an examination of the volume before us indicates that the fruition has justified the hope. If there be any fault in the book, it is simply that of overfulness. The physician who writes his own prescriptions has very little need for a general treatise on pharmacy, but to him who lives in the country, and has the time and desire necessary for even the pretence of elegance in pharmacy, this work will prove invaluable. It is composed of nearly one thousand pages of clear type, with a free use of the smaller type. We note the facsimiles of prescriptions given on page 921 as being of such a nature that we thank Providence that it is not our lot to be an apothecary

and to decipher them. If the choice were allowed, we would prefer working out Egyptian hieroglyphics.

As the volume of Professor Remington is pharmaceutical rather than medical, it is hardly our province to review it in detail. It is sufficient to indicate to our readers that it embodies all that is known upon the subject of which it treats, and to recommend it most highly to any one desirous of possessing such a treatise. We congratulate Professor Remington upon the completion of his years of labor, and express the firm belief that he will reap the reward of a large and persistent sale.

#### REVUE SCIENTIFIQUE.

The following is a summary of the table of contents of the *Revue Scientifique* for the past month:

November 28, 1885:

*Physiology.*—Cerebral Excitability after Death. By M. Laborde.

*History of the Sciences.*—Van Helmont. By M. Laboulbène.

*Miscellany.*—Posthumous Memoirs of Pirogoff.

*Aeronautics.*—New Experiments with a Dirigible Aerostat. By M. Renard.

*Book Notices.*—History of the Heavens (by M. Ball); German Psychology (M. Ribot).

*Proceedings of the Academy of Sciences of Paris.*

*Correspondence.*

December 5, 1885:

*The Death of M. Bouley.*

*Anthropology.* Prehistoric Life. By M. Letourneau.

*Terrestrial Physics.* The Climate of Alsace. By M. Grad.

*Psychology.*—Manifestations of Intelligence in a Bird. By M. de Lacaze-Duthiers.

*Physiology.*—The Thermic Sense. By M. Herzen.

*Book Notices.*—Clinical Studies on Hysteria (Richer); The Pathogenic Microbes (M. Artigalas); Cholera and Ferran (M. Duhourcau); The Great Sympathetic in Disease (M. Long-Fox).

*Proceedings of the Academy of Sciences of Paris.*

*Correspondence and New Inventions.*

December 12, 1885:

*Biology.*—Acclimatization and Europeans in the Colonies. By M. Virchow.

*Hygiene.*—Hygienic Improvements in Paris. By M. Héricourt.

*Geography.*—The Exploration of Me-Kong. By M. Réveillière.

*Astronomy.*—The Fall of Stars on November 27, 1865. By M. Barré.

*Book Notices.*—The Equality of the Human Races. By M. Firmin.

*Proceedings of the Academy of Sciences of Paris.*

*Correspondence.*

December 19, 1885 :

*Chemistry.*—Matter, Forces, and Affinity. By Armand Gautier.

*Anthropology.*—The Anthropological Congress at Carlsruhe.

*Miscellany.*—Public Instruction in Tunis. By M. Fontin.

*Geology.*—The Geysers in America and Iceland. By M. Leclercq.

*Book Notices.*—Lectures on the History of Medicine (M. Thomas) ; Railroad Transport of Wounded (M. Redard).

*Proceedings of the Academy of Sciences of Paris.*

*Correspondence.*

## Correspondence.

### BERLIN.

(From our Special Correspondent.)

*THE USE OF THE COLD COMPRESS—INFANT FEEDING-BOTTLES—THE BACILLI OF SYPHILIS—GERMAN METHODS OF TEACHING MEDICINE—COMPULSORY VACCINATION—NOTES—TREATMENT OF ECZEMA.*

Among the therapeutic measures in vogue in Germany there is none which attracts the attention of the American physicians so eminently as the water-compress. It is no fable that the "compress," as it is briefly called, is prescribed for every affection of the throat and lungs ; for a clinical experience of nearly three months in the Charité and other hospitals convinced your correspondent that it is the first thing ordered in nearly every ailment of the respiratory tract. A piece of linen, being of the size of a napkin if intended for the throat, or of the size of a towel if intended for the lungs, is dipped into cold—not lukewarm—water, applied to the desired locality, and retained *in situ* by means of a woollen shawl or oil-silk, and renewed every half-hour. A poultice is never exhibited for these affections. The compress, as may be expected, has also become the routine treatment in every household, and is

quite familiar to every mother and nurse. Your correspondent has taken especial pains in tracing the therapeutic results of this procedure—which, of course, is often accompanied by medicinal treatment—and feels highly gratified with the results observed. The value of this hydriatic procedure consists in the frequent renewals and prolonged application—extending often over two to three days—of a medium which not only abstracts the surplus of heat in the part, and by its secondary physiological action dilates the vessels of the integument, and thus relieves the engorged internal parts, but which also has an undeniable invigorating influence on the nervous system. It seems superfluous to add that strict individualization is—as in all hydriatic procedures—an indispensable requisite in the application of the cold compress. If in a patient the nervous energy is profoundly lowered, the application of cold would naturally only deepen the existing prostration and lessen the resistance against the disease. If, however, we deal simply with a loss of innervation, the usual incumbent of nearly every affection, the application of cold would prove a powerful stimulant to the nerve-centres, and alongside of the above-mentioned local effects of the application, materially fortify the chances of recovery.

The old maxim that the treatment of an affection is in most instances an easy matter, provided a correct diagnosis has been established and the etiological factors are well understood, is strikingly illustrated by the digestive disorders of children that can be directly traced to the numerous existing patent nursing-bottles. In the children's department at the University Hospital of Berlin there is a collection of some three hundred nursing-bottles of various sizes and shapes, all provided with a long rubber tube, which enclose a piece of litmus-paper colored red. No commentary is needed. It is quite clear that the presence of lactic acid in the tube suffices to explain many obscure disorders of the alimentary tract for which the physicians are often at a loss to find a satisfactory explanation. Your correspondent has repeatedly witnessed that mothers returned to the Polyclinic and testified to the rapid recovery of their children after withdrawal of the patent nursing-bottles. In one instance the tube was found to be made of lead, and to have given rise to serious constitutional symptoms in addition to the gastric irritation. In view of these facts the attending physicians of the Polyclinic make it an invariable rule to inquire as to the nature of

the nursing-bottle in every child presented for treatment on account of digestive disorders.

In a lecture on bacteriology, held in the Hygienic Institute on the 9th of December, Prof. Koch denied that Lustgarten's syphilis-bacilli could at the present state of affairs be regarded as fully diagnostic and pathognomic, as the microbes detected in the smegma of the prepuce showed the same appearance and behavior as to coloration and general chemical tests. It is fair to add, however, Koch said, that Dutrelepont had recently endeavored to show that by a complicated coloration process the smegma-bacilli presented a definite difference of behavior from that of the syphilitic parasites detected in various parenchymatous tissues. But as long as Dutrelepont's claims lack a firm substantiation, Lustgarten's bacilli can, according to Koch's views, not yet be invested with an absolute diagnostic character. In the course of the same lecture Koch also referred to the singular and still unexplained identity of the bacilli of tuberculosis and leprosy.

There is an essential difference in the method of teaching the practice of medicine between Germany and America. All the lectures on practice of medicine are delivered in the hospital amphitheatres alongside of the patient, who serves as the illustration of the subject of the discourse. One student is called up by the professor to act as "practicant," to interrogate the patient, to diagnose the case, and to suggest the appropriate treatment. After that the professor delivers his lecture with especial reference to the peculiarities of the case present. It is evident that the impression produced by these practical and demonstrative lectures is far greater than that of mere didactic teaching, such as forms still the main source of instruction for many American students.

The question whether or not vaccination should be enforced as an obligatory measure is at present receiving in Germany an unusual attention. The appearance of an epidemic, marked by an erysipelatous rash and constitutional disturbance, on the island of Rügen (in the Baltic Sea), which is charged directly to vaccination, has naturally confirmed the claims of the opponents of this procedure, to abolish, at least, compulsion in the matter. While the fairness of this demand cannot be questioned, the German government is little disposed to comply with it in view of the remarkable results which vaccination has furnished in the army according to thoroughly reliable statistics. The following interesting

data on the value of vaccination, given by Prof. Koch in his opening lecture on hygiene, must be regarded as a powerful argument in favor of compulsory vaccination. Before the introduction of vaccination, Koch said, smallpox was a disease which, like measles at present, attacked nearly everybody and killed about one-twelfth of the human race. In Sweden, where we find reliable statistics even from the last century, according to the records eighty thousand people died annually of smallpox, while the number of deaths from this cause, after introduction of compulsory vaccination, amounts only to eight hundred to one thousand. In other words, seventy-nine thousand people are being saved annually in that country by vaccination. It would be a hard matter to overthrow so forcible an argument as is contained in these figures, provided they should be reliable. In the latest annual issue of the Imperial Health Office Reports, however, we find the following affections figuring as alleged sequelæ of vaccination, which might well deter a timid mater familias from exposing her child to the possible dangers lurking in vaccination:

1. Inflammation of the skin.
2. Inflammation of the lymphatic vessels and glands.
3. Inflammation and suppuration of the cellular tissue, five cases with a fatal issue.
4. Erysipelas, nine deaths.
5. Ulcerations and two deaths (from septicæmia).
6. Acute and chronic skin-eruptions.

A transmission of syphilis has in no instance been observed.

That learning and humanity do not necessarily go hand in hand has been very clearly shown by the practice and decisions of the military school at Spandau (near Berlin). To ascertain the penetrating power of a certain new shot, living horses, which were previously chloroformed, were fired upon. It is hard to recall, of all inhuman and brutal acts on record in the world's history, an act more revolting and disgraceful than this practice ordered by the Secretary of War of a nation claiming to be the most educated of all. From a medical point of view we fail to see what possible benefit in this especial instance chloroform could produce. Why not use cadavers, which would, in every imaginable respect, have answered the same purpose?

There is a still more ignominious issue connected with this affair. When Dr. Foerster, president of the Berlin Society for the Prevention of Cruelty to Animals, petitioned the

Secretary of War to inhibit this inhuman practice on the most noble and useful of animals, the wise and just secretary ordered Dr. Foerster to be indicted for gravely insulting the authorities of the military college. In spite of Dr. Foerster's plea that he was led to his petition by mere motives of humanity, he was sentenced to pay a fine of one hundred marks, which sum was afterwards reduced to thirty-five marks.

The catalogue of the Berlin University just issued contains among the number of attending students—over six thousand five hundred—the names of one hundred and twenty-five Americans who have duly matriculated. The chief attractions for the American student or physician (for they all have obtained their degree at home) are the clinics of Schröder and Gusserow in gynaecology, Bardeleben and Bergmann in surgery, Hensch in pædiatrics, and the laboratories of Koch and Virchow.

The concentration of the first authorities of Germany at the Berlin University has made Berlin unquestionably the greatest medical centre of the continent, a rank which a few years ago was claimed by Vienna. The American student is allowed to matriculate on the strength of his passport, without being compelled to present any college degree, while for every German the graduation-papers from a gymnasium—a classical high school, with a nine years' course—are a *conditio sine quâ non*. These requisites insure a uniform and high literary level, which differs very favorably from the mixed status still to be found in some of our American colleges. Though, according to American views, Latin and Greek are not indispensable requisites to the study and practice of medicine, we must admit that it is desirable to raise the standard of the profession at home to a higher level than it occupies at the present day. Of this one grows especially conscious after having met the English and German colleagues. There is no doubt, however, that probably in the near future the American physician will, in all respects, be the peer of his European *confrères*.

The pustulous eczema appearing on the head, face, and eyelids, which so often leads to irreparable injury to the conjunctiva and cornea, is treated by Burkhardt, in the Berlin Charité, in the following manner: After a careful softening of the part, and dissolving of the crusts, the part is brushed with a three per cent. solution of nitrate of silver. This application is made at first daily,

later only every second day, until healing sets in. Immediately after cauterization the application of the following ointment materially assists the healing process:

R Flor. zinci, 2 parts;  
Olei cad., 1 part;  
Vasel., 10 parts.

Burkhardt's treatment has proven a success in a very large number of cases.

A papilloma of the upper surface of the tongue, of the size of a three-cent piece, appearing in a young child, was treated by Dr. Schwecten, in the Charité, by the solid silver stick and immediate application of a saturated chloride of sodium solution. This simple procedure was so successful that the tumor disappeared wholly in about a week's time.

#### THE CHLOROFORM TREATMENT OF TAPEWORM.

Editors of the THERAPEUTIC GAZETTE:

I have the honor of being a subscriber and interested reader of your journal, and on pages 759 and 784 of No. 11, issued November 16, 1885, I read two articles on the use of chloroform in the treatment of tapeworm; the former, by Dr. Bennett, of Brooklyn, simply stating his success in the employment of the remedy, and the latter, by Dr. Sampson Pope, of South Carolina, claiming credit of the discovery for Dr. Simonds, of Texas.

While I do not for a moment doubt Dr. Pope's assertion, I simply wish space in your valuable journal to give due credit to another very worthy member of our noble profession.

To my knowledge, Dr. F. G. Horn, of Colorado Springs, Col., used chloroform in the treatment of tapeworm in 1872, and, meeting with decided success, he continues its use.

Very respectfully,

C. A. SIGLER, M.D.

EL DORADO, KANSAS.

#### NOTES ON COCAINE.

To the Editors of the THERAPEUTIC GAZETTE:

GENTLEMEN:—I wish to add a mite to the records of cocaine hydrochlorate. Appreciating that the notes on cocaine have already become very voluminous, I will be as brief as possible, and beg your indulgence, on the ground that in a multiplicity of evidence must the merits of this local anæsthetic gain a lasting foothold. It to the ophthalmologist is a *sine quâ non*,—the anæsthetic *par excellence*. Among my most recent cases was a case of

strabismus convergens alternans. Young lady aged 23 years; operated upon both eyes at one sitting. Used in all 20 drops of eight per cent. solution, and waited half an hour from time of first instillation before commencing the operation. Used a drop or so about every five minutes. The operation was nearly bloodless and painless, and she scarcely felt the strabismus-hooks. Found also that the greatest point achieved, aside from the complete anæsthesia of the balls, was that the eyes could be immediately tried as to the power of convergence, and if any defects were observed the hooks could be again passed, and the remaining portions of tendinous attachments severed. This cannot be done where chloroform or ether is used, and maybe the surgeon's reputation greatly imperilled, and his fee withheld, and he so compromised that maybe the patient would not again submit to an operation. With cocaine all this is avoided. I have also found cocaine indispensable in tattooing corneal leucoma for cosmetic effects, and for the removal of foreign substances imbedded in the cornea. I have used it repeatedly, and have never been disappointed in its action.

Among the most important cases was one recently of acute glaucoma of left eye. Eye perfectly blind, painful, pupil dilated, and all the other usual symptoms. First instilled strong sol. eserine sulphuric; then at intermissions of some five minutes for half an hour instilled a drop of an eight per cent. solution of cocaine hydrochlorate, and proceeded with the iridectomy, which proved nearly painless, and the eye made a complete and rapid recovery,  $s = \frac{1}{10}$ .

Used cocaine again in the removal of a very large pterygium complicated with symblepharon and dense corneal opacity. The operation was nearly bloodless and painless, and after the dissection the surface was cleansed carefully and dried, and cocaine again applied, and the ocular conjunctiva dissected up from near two-thirds from above and below, and the exposed surface covered. The sutures held nicely, and the eye has made a handsome recovery, with scarcely any reaction after the operation.

Operated one week ago to-day upon the eyes of a young girl aged 13 years. Case of acute glaucoma, both eyes, caused from congenital ectopia lentis, both eyes. Right dislocated downwards and inwards, and left lens into anterior chambers. In this case used chloroform by inhalation, and also cocaine locally, and eserine. Cocaine was used for a

double purpose,—first, to prevent vomiting from any relaxation, and also that in case the chloroform-anæsthesia should chance to fail at the critical moment we could go on and finish the operation without pain to the patient; and such an emergency did partially happen when we came to the operation upon the left eye; but the cocaine did its work, and we had as much time as could be desired. In the right eye we have a handsome iridectomy, and the eye healed quickly, and without any reaction; and sight is good, as the lens was clear; but in the left eye the lens was tough and amber-colored, and bound down tightly by adhesions to the iris, which (the latter) was found to be a hard sclerosed ring; and we could not remove the lens, but proceeded by division, and bound up the eye, and expected rapid setting in of post-ophthalmitis; but nothing much unusual has happened; and while in this eye we do not expect any sight, yet we will have a fair-looking eye. The notes on this case as here given are very incomplete, and we wish to report it very fully in some ophthalmic journal, for it has proved one of rare interest to all interested.

C. A. LAMBERT, M.D.

GOSHEN, IND., December 15, 1885.

---

## Notes and Queries.

---

### DISINFECTANTS.

The following are the conclusions drawn from the reports of the Committee on Disinfectants of the American Public Health Association:

The most useful agents for the destruction of spore-containing infectious materials are:

1. Fire. Complete destruction by burning.
2. Steam under pressure.  $110^{\circ}$  C. ( $230^{\circ}$  F.) for ten minutes.
3. Boiling in water for one hour.\*
4. Chloride of lime.† A four per cent. solution.
5. Mercuric chloride. A solution of 1 to 500.

For the destruction of infectious material which owes its infecting power to the presence of micro-organisms not containing spores, the Committee recommended:

---

\* This temperature does not destroy the spores of *B. subtilis* in the time mentioned, but is effective for the destruction of the spores of the anthrax bacillus and of all known pathogenic organisms.

† Should contain at least twenty-five per cent. of available chlorine.

1. Fire. Complete destruction by burning.
2. Boiling in water half an hour.
3. Dry heat.  $110^{\circ}$  C. ( $230^{\circ}$  F.) for two hours.
4. Chloride of lime.\* One to four per cent. solution.
5. Solution of chlorinated soda.† Five to twenty per cent. solution.
6. Mercuric chloride. A solution of 1 to 1000 to 1 to 4000.
7. Sulphur dioxide. Exposure for twelve hours to an atmosphere containing at least four volumes per cent. of this gas, preferably in presence of moisture.‡
8. Carbolic acid. Two to five per cent. solution.
9. Sulphate of copper. Two to five per cent. solution.
10. Chloride of zinc. Four to ten per cent. solution.

The Committee would make the following recommendations with reference to the practical application of these agents for disinfecting purposes :

*For Excreta.*

- (a) In the sick-room :
- For spore-containing material :
1. Chloride of lime in solution, four per cent.
  2. Mercuric chloride in solution, 1 to 500.§
- In the absence of spores :
3. Carbolic acid in solution, five per cent.
  4. Sulphate of copper in solution, five per cent.
  5. Chloride of zinc in solution, ten per cent.

(b) In privy-vaults :

Mercuric chloride in solution, 1 to 500.¶

(c) For the disinfection and deodorization of the surface of masses of organic material in privy vaults, etc. :

\* Should contain at least three per cent. of available chlorine.

† This will require the combustion of between three and four pounds of sulphur for every thousand cubic feet of air-space.

‡ The addition of an equal quantity of potassium permanganate as a deodorant, and to give color to the solution, is to be recommended (*Standard Solution No. 2*).

§ A concentrated solution containing four ounces of mercuric chloride and one pound of cupric sulphate to the gallon of water is recommended as *Standard Solution No. 3*. Eight ounces of this solution to the gallon of water will give a dilute solution for the disinfection of excreta, containing about 1 to 500 of mercuric chloride, and 1 to 125 of cupric sulphate.

¶ For this purpose the chloride of lime may be diluted with plaster of Paris, or with clean, well-dried sand, in the proportion of one part to nine.

Chloride of lime in powder.‡

*For Clothing, Bedding, etc.*

(a) Soiled underclothing, bed-linen, etc. :

1. Destruction by fire, if of little value.
2. Boiling for at least half an hour.
3. Immersion in a solution of mercuric chloride of the strength of 1 to 2000 for four hours.§
4. Immersion in a two per cent. solution of carbolic acid for four hours.

(b) Outer garments of wool or silk, and similar articles, which would be injured by immersion in boiling water or in a disinfecting solution :

1. Exposure to dry heat at a temperature of  $110^{\circ}$  C. ( $230^{\circ}$  F.) for two hours.
2. Fumigation with sulphurous acid gas for at least twelve hours, the clothing being freely exposed, and the gas present in the disinfection-chamber in the proportion of four volumes per cent.

(c) Mattresses and blankets soiled by the discharges of the sick :

1. Destruction by fire.
2. Exposure to superheated steam—twenty-five pounds pressure—for one hour. (Mattresses to have the cover removed or freely opened.)
3. Immersion in boiling water for one hour.
4. Immersion in the blue solution (mercuric chloride and sulphate of copper), two fluid-ounces to the gallon of water.¶

*For Furniture and Articles of Wood, Leather, and Porcelain.\*\**

Washing, several times repeated, with,—

1. Solution of mercuric chloride, 1 to 1000. (The blue solution, four ounces to the gallon of water, may be used.)
2. Solution of chloride of lime, one per cent.
3. Solution of carbolic acid, two per cent.

*For the Person.*

The hands and general surface of the body of attendants, of the sick, and of convalescents at the time of their discharge from hospital :

1. Solution of chlorinated soda diluted with nine parts of water (1 to 10).
2. Carbolic acid, two per cent. solution
3. Mercuric chloride, 1 to 1000 ; recommended only for the hands, or for washing

¶ The blue solution containing sulphate of copper, diluted by adding two ounces of the concentrated solution to a gallon of water, may be used for this purpose.

\*\* For articles of metal, use Solution No. 3.

away infectious material from a limited area, not as a bath for the entire surface of the body.

*For the Dead.*

Envelop the body in a sheet thoroughly saturated with,—

1. Chloride of lime in solution, four per cent.
2. Mercuric chloride in solution, 1 to 500.
3. Carbolic acid in solution, five per cent.

*For the Sick-Room and Hospital Wards.*

(a) While occupied, wash all surfaces with,—

1. Mercuric chloride in solution, 1 to 1000 (the blue solution containing sulphate of copper may be used).
2. Chloride of lime in solution, one per cent.
3. Carbolic acid in solution, two per cent.

(b) When vacated :

Fumigate with sulphur dioxide for twelve hours, burning three pounds of sulphur for every thousand cubic feet of air-space in the room ; then wash all surfaces with one of the above-mentioned disinfecting solutions, and afterwards with soap and hot water ; finally throw open doors and windows and ventilate freely.

*For Merchandise and the Mails.\**

The disinfection of merchandise and of the mails will only be required under exceptional circumstances ; free aeration will usually be sufficient. If disinfection seems necessary, fumigation with sulphur dioxide, as recommended for woollen clothing, etc., will be the only practicable method of accomplishing it.

*For Rags.*

(a) Rags which have been used for wiping away infectious discharges should at once be burned.

(b) Rags collected for paper-makers during the prevalence of an epidemic should be disinfected before they are compressed in bales by,—

1. Exposure to superheated steam (twenty-five pounds pressure) for ten minutes.
2. Immersion in boiling water for half an hour.

(c) Rags in bales can only be disinfected by injecting superheated steam (fifty pounds pressure) into the interior of the bale. The apparatus used must insure the penetration of the steam to every portion of the bale.

\* In order to secure penetration of the envelope by the sulphur dioxide, all mail matter should be perforated by a cutting-stamp before fumigating.

*For Ships.*

(a) Infected ships at sea should be washed in every accessible place, and especially the localities occupied by the sick, with,—

1. Solution of mercuric chloride, 1 to 100 (the blue solution heretofore recommended may be used).
2. Solution of chloride of lime, one per cent.
3. Solution of carbolic acid, two per cent.

The bilge should be disinfected by the liberal use of a strong solution of mercuric chloride (the concentrated solution—"blue solution"—of this salt with cupric sulphate may be used).

(b) Upon arrival at a quarantine station an infected ship should at once be fumigated with sulphurous acid gas, using three pounds of sulphur to every thousand cubic feet of air-space ; the cargo should then be discharged on lighters ; a liberal supply of the concentrated solution of mercuric chloride (four ounces to the gallon) should be thrown into the bilge, and at the end of twenty-four hours the bilge-water should be pumped out and replaced with pure sea-water ; this should be repeated. A second fumigation after the removal of the cargo is to be recommended ; all accessible surfaces should be washed with one of the disinfecting solutions heretofore recommended, and subsequently with soap and hot water.

*INJECTION OF A NEW PREPARATION OF  
ALBUMINATE OF MERCURY IN  
SYPHILIS.*

DR. MAX BOCKHART, of Wiesbaden, describes, in a German dermatological journal, an ingenious method of administering mercury in syphilitic cases by subcutaneous injection, which, he says, is perfectly innocuous, never having caused pain, induration, or abscess. He combines the mercury with blood-serum. The latter, which may be obtained from the horse, sheep, or ox, is sterilized according to Koch's process, and then filtered. Of the filtrate, 40 cubic centimetres (1½ oz.) is poured into a graduated glass. To this is added a warm (50° Cent.) solution of 3 grm. (45 grs.) of bichloride of mercury in 30 grammes (1 oz.) of water. The resulting precipitate is dissolved in a solution of 7 grm. (105 grs.) of common salt in 20 grammes (5 drachms) of water. This gives a three per cent. solution of mercury blood-serum. This is then mixed with distilled water, so that the whole weighs 200 grammes (6¼ oz.), which

reduces the strength to one and a half per cent., which is the best strength for use; a gramme (15 grs.) of it containing 0.015 gramme ( $\frac{1}{8}$  gr.) of mercurial albuminate. This solution is a yellowish opalescent liquid, with neutral reaction, and will keep very well in a dark glass bottle in a cool place. The injections are given once or twice a day, 0.7 gramme (12 gtt.) being introduced on each occasion, containing about 0.01 gramme, or  $\frac{3}{8}$  of a grain of albuminate of mercury. Besides acting rapidly and powerfully on syphilis, and keeping the system for a long period free from secondary symptoms, this preparation has the advantage of being stable, cheap, and easily prepared.—*British Med. Journ.*, October 10, 1885.

#### COCAINE IN SEA-SICKNESS.

DR. J. B. BISSELL writes to the *Medical Record*, December 19, 1885, as follows: "Cocaine has been recently recommended as a remedy in sea-sickness, particularly by a Russian physician, who claims to obtain speedy and certain relief by its use in this affection. In a voyage from New York to Charleston, S. C., made in November of this year, an excellent opportunity was afforded to ascertain the value of the drug in this regard. The time of passage was four days, the weather fair, and no storms, but a head-wind lasted all the way. The experiments were made on twenty-seven persons of both sexes, and from 4 years of age to 48. The hydrochlorate of cocaine, in doses of  $\frac{1}{16}$  and  $\frac{1}{8}$  of a grain, in tablets, was given by mouth. In one set of cases the medicine was begun soon after leaving the wharf; in another set at the first symptom of nausea; in the third set not till vomiting had taken place. In the first set the dose was  $\frac{1}{16}$  of a grain, repeated every hour till 2 grains had been taken. In the other cases  $\frac{1}{8}$  every fifteen minutes up to 2 grains, or, as happened in nearly every case, till the patients became so sick that they refused to continue the drug. This was usually after the fifth or six dose. The results from these three sets of cases were almost precisely similar. In twelve cases there was no improvement, if the treatment did not positively make the patients worse. In six cases there was certainly an increase in the severity of the symptoms. In only three of the twenty-seven cases was there apparent benefit, and this improvement was coincident with a temporary improvement of the weather. As the sea became rougher all three relapsed, and, in spite of the

cocaine, became very sick. The other six of the twenty-seven were at sea for the first time. One of these was not sick at all during the trip. The others, however, did not escape. I did not notice any special influence exerted by the age or sex of the person treated. Such results as the above ought to dispose of cocaine as a remedy in sea-sickness, but as these results do not advertise any one's special method of administering the drug, or any firm's special preparation, it is very likely it will continue to be used till a newer remedy comes into fashion."

#### ON THE INFLUENCE OF VASELINE ON DIGESTION.

Vaseline is at present so frequently employed for pastry and other eatables instead of butter and fat, that the question whether or not this substance exerts an objectionable influence on the digestive system is worthy of attention.

In the meeting of the Biological Society of Paris, held on the 14th of November, 1885, DR. DUBOIS discussed this subject, and presented the results of his researches (vide *Gazette Hebdomadaire* of November 27, 1885).

The most instructive of his experiments instituted for this purpose were those of two dogs, who ingested for a period of six consecutive days 25 and 15 grm. (375 and 275 grs.) daily without experiencing any appreciable disturbance of the digestive apparatus. These quantities correspond to about 100 to 60 grm. in man, taking weight as the criterion. Dubois states that, against all anticipation, vaseline is not ill borne by the stomach; although, as a carbohydrate, it would be *a priori* regarded as an impediment to the digestive functions.

#### THE GELSEMIUM HABIT.

DR. H. C. CALDWELL reports in the *Med. and Surg. Herald*, October, 1885, the peculiar case of a man who became addicted to the use of gelsemium. In an attack of rheumatism he took large doses of the fluid extract of gelsemium, which was followed by relief, and the next day was repeated under similar circumstances with the same result. Using it for some time in this way he became addicted to the habit, and finally used as much as a fluidounce of the extract at one dose. He became pale, emaciated, restless, and uneasy, and was a subject of hallucination. This

condition continued to increase until he became finally almost idiotic, and the dose being daily increased, until after a year he sank into a condition of hopeless idiocy, and died in a stupor induced by this drug.

#### COLD BANDAGING OF THE LEG IN INSOMNIA.

DR. VON GELLHORN has found the following plan very useful in inducing sleep in persons who suffer from insomnia. A piece of calico, about eighteen inches wide and two and three-quarter yards long, is rolled up like a bandage, and a third of it wrung out of cold water. The leg is then bandaged with this, the wet portions being carefully covered by several layers of the dry part, as well as by a layer of gutta-percha tissue, and a stocking drawn on over the whole. This causes dilatation of the vessels of the leg, thus diminishing the blood in the head and producing sleep. It has been found by Winternitz that the temperature in the external auditory meatus begins to fall a quarter of an hour after the application of the bandage; the decrease amounting to  $0.4^{\circ}$  Cent., and the normal not being again reached for from one and a half to two hours afterwards. The author has employed this means of procuring sleep for a couple of years, and finds it especially useful in cases where there is congestion of the cerebral vessels. Sometimes he has found it necessary to reapply the bandage every three or four hours, as it dried.—*British Med. Journ.*, November 7, 1885.

#### THE INCOMPATIBILITY OF ANTIPYRIN WITH SWEET SPIRITS OF NITRE.

We have already referred, in a previous issue, to the fact that when antipyrin in aqueous solution is added to sweet spirits of nitre a deep green color is gradually assumed, and after standing several hours beautiful green crystals are deposited. This reaction has been investigated by MR. JAMES KENNEDY (*Pharm. Record*, December 15, 1885), who found that when antipyrin was dissolved in ethyl nitrite or amyl nitrite the solution always deposited it in crystalline form on standing for some hours. When antipyrin is mixed with a solution of potassium nitrite the solution immediately assumes a green color, but does not deposit the green crystals.

After making some further experiments, he concluded that the formation of the new compound was due to the combination of the acid or nitrous radical with antipyrin, and proved

the correctness of his theory by obtaining the compound from aqueous solution of antipyrin by saturating it with ( $\text{N}_2\text{O}_5$ ) or (NO) gas (generated by action of  $\text{HNO}_3$  on Cu), the compound being but very sparingly soluble in water crystallized out.

It crystallizes in minute tabular crystals having a beautiful green color.

It is an acid, and has the property of reddening litmus-paper, and combines with alkalis, but is precipitated from its combination on addition of HCl.

It is sparingly soluble in cold water, but is entirely dissolved by boiling water (being again deposited on cooling).

It is soluble in ether, alcohol, and benzol, but is insoluble in chloroform.

He also mentions another peculiar compound which it is capable of forming:

When antipyrin is treated with Nessler's reagent in excess the mixture become turbid, and in a few moments separates into two distinct layers. The lower layer is of a pale yellow color and has an oily appearance, and is a compound of antipyrin with iodide of mercury. It is decomposed by addition of water in excess with separation of yellow or proto-iodide of mercury.

Antipyrin is a very soluble substance, dissolving readily in all ordinary solvents. Its aqueous solution is not precipitated by the hydroxides of potassium, sodium, or ammonium, but gives precipitates with mercuric chloride, tannic acid, and iodine. It is *not* precipitated by soluble iodides. When gently heated it melts to a colorless liquid, and solidifies to a crystalline mass on cooling. Exposed to higher heat it sublimes with partial decomposition. The vapors are inflammable.

#### THE ACTION OF ALKALIES ON ALOES.

It is well known that the addition of bicarbonate of sodium or potassium to solutions of aloes considerably diminishes their bitterness, and DR. MACDONALD (*Moniteur de la Pharmacie*, November, 1885) has attempted to determine whether or not this addition to aloes at the same time diminishes their medicinal properties. A proportion of forty parts of aloes, seventy-five of bicarbonate of sodium, to a thousand of water, was divided into two parts; the one was carefully sealed, the other remained exposed to the air. Two months later the latter portion had entirely lost its bitterness, while in the first it was completely preserved. Therapeutic experiments made with these two proportions show that both

had still very active properties, but that the bitter solution was at least three times as active as the other.

#### CASE OF POISONING BY NITRATE OF POTASSIUM.

In the course of an exceedingly interesting article, DR. LITTLEJOHN gives an account of a fatal case of poisoning with nitrate of potassium, supposed to be the only recorded case of criminal administration of nitre (*Pharmaceutical Journal and Transactions*, November 21, 1885).

The victim was a boy of 3, the son of a single woman. The boy was robust, and when he left the house with his mother at 5.35 on a Friday afternoon he was in his usual good health. When he returned at six o'clock he was cold, sick, and vomiting. Afterwards he vomited repeatedly and was violently purged. The mother refused to call medical assistance, and the boy died at 8 P.M. Dr. Littlejohn having been asked for a medical certificate, the inquiries which he made raised his suspicions, and he thought it right to inform the police authorities of the case. A post-mortem examination was accordingly ordered, and on examining the stomach Dr. Littlejohn's suspicions were confirmed. He says, "I shall never forget the striking appearance of vivid congestion which it presented as contrasted with the generally normal condition of the rest of the body."

An order for analysis was intrusted to Prof. Maclagan and Dr. Littlejohn. Search was made for the metallic irritant poisons, but without success; neither arsenic, mercury, zinc, nor oxalic acid was present. Subsequently Dr. Littlejohn learnt that on the toe of one of the child's boots there was the appearance of some minute crystals. On examination with a lens these proved to be prismatic and fluted, and Prof. Maclagan pronounced them to be nitre. The brucine test was applied, and the characteristic vivid red reaction obtained. "No time was lost in completing the analysis, and as the result nitre was detected in the mucous lining, the stomach, and the intestines, in the liver, lung, kidney, brain, and in the blood. From the stomach it was separated in the crystalline form; in the other organs the reactions with brucine and iron were well marked. In the brain and blood the iron test was not decisive, but the brucine test showed the presence of nitre very distinctly." The poison was also found on various articles of clothing worn by the child before death.

The mother had cleared away all discharges which passed from it, but on two pieces of cloth which were stained with fæcal matter nitre was found. Prof. Maclagan and Dr. Littlejohn reported "that from our whole experiments we can come to no other conclusion than that this child must have swallowed a very large dose of nitre, which had not only impregnated the blood and all the organs, but had been discharged in considerable quantity in the matters vomited and passed by stool."

As to the purchase of the poison, a grocer stated that he recollected selling the woman a small packet of nitre, but he failed to identify her in a proper manner. Other important links in the chain of evidence being wanting, the jury returned a verdict of "not proven."

In concluding the paper Dr. Littlejohn remarks, "The taste and rapidity of its action are naturally serious obstacles to the use of nitre by the poisoner, and, as the present case shows, children are the most likely victims. The wonder is that with the unusual facilities for the purchase of such an active poison we do not hear of nitre being more frequently employed."

#### ARTIFICIAL COCAINE.

MERK succeeded in transforming benzoyl-ecgonin, a new substance discovered by him, into cocaine, as reported by the *Pharm. Zeitung* of October 31, 1885. It might interest some of the more speculative minds to know how to prepare the costly alkaloid without the Peruvian plant.

Several grammes of benzoyl-ecgonin are heated to 100° (C.) with iodide of methyl and methylic alcohol, and then slowly evaporated. The product is a hydrate of iodine, and conforms to all tests of genuine cocaine, and even has the same melting-point as the latter (98°).

#### AN IMPROVED METHOD OF OPERATING FOR CLEFT PALATE.

A correspondent writes to *The Lancet*, November 7, 1885, concerning what he considers a great improvement in the operation for cleft palate. Hitherto great difficulty and not a little danger have arisen from hemorrhage during the operation, necessitating frequent and very skilful assistance, periodical discontinuation of the anæsthetic, and distinct intervals in the performance of the operation. In addition to these, other and minor troubles are experienced. All these difficulties may be avoided, and the operation rendered perfectly

safe and easy, by the simple process of inversion as applied to the head only. This can easily be attained by bringing the patient's shoulders well up to the end of the operating-table, and allowing the head to hang over the edge in the fully extended position. In this position the roof of the mouth would be horizontal or slightly inclined downward towards the operator, who should stand at the head of his patient. The anæsthetic is given through the nose by a small tube, and is quite out of the way of the surgeon. Only one assistant is required, who should stand to the left of the operator. In paring the edges no change of hands is required, but the corresponding hand should be used in elevating the tissues of the hard palate and in passing the sutures. Under these circumstances no blood can enter the larynx or œsophagus, the palate remains unobscured by blood, and whatever hemorrhage occurs finds its way into the nasal cavities, and at the conclusion of the operation may be emptied by simply turning the patient's head to one side.—*Medical Record*, December 5, 1885.

#### THE TREATMENT OF DIABETES MELLITUS WITH BORACIC ACID.

MR. F. A. MONCKTON reports in the *Australasian Gazette* (October, 1885) a case of a boy, aged 14, suffering from diabetes mellitus, with all the symptoms in an aggravated form, who was apparently cured by the use of boracic acid in 7-grain doses three times daily. At first there were no stringent dietary regulations, and even in the later part of the treatment only sugar, potatoes, and oatmeal were forbidden. Bread was eaten at the meals in the ordinary way. He gradually gained in weight, his health improved, and the sugar disappeared from the urine.

#### TREATMENT OF A REBELLIOUS CORN.

DR. R. C. NEWTON, Assistant Surgeon, U.S.A., writes to the *New York Medical Record*, November 7, 1885, from Fort Elliott, Texas, concerning a soldier, 33 years of age, who was suffering from a large callosity, caused by a splinter which he had run into the sole of his foot two years ago. The callosity resembled an ordinary corn, but was as large around as a quarter of a dollar, and gave but little pain except when the man walked about. The corn was vigorously treated by excision, poulticing, scraping, salicylic acid, cannabis indica, collodium, etc.,

but without avail, for each time that it was removed it grew again with most commendable persistency. Anti-syphilitic treatment was also tried without success. Finally Dr. Newton had resort to liquor potassæ, as recommended by Erichsen for callosities, and, after making applications twice a day with this substance for a period of four months, was rewarded by seeing his patient cured and returned to duty.

#### THE EMPLOYMENT OF ANTIPYRIN IN THE TREATMENT OF EPISTAXIS.

DR. LAVRAND (*Journ. de Méd.*, November, 1885) refers to two cases which seem to show that antipyrin possesses the power of arresting epistaxis. Dr. Lavrand used it in the form of a three per cent. solution. It is employed by soaking a morsel of cotton in this solution, and then introducing it into the nostril, which is then closed by making pressure with the finger over the compress.

#### THE TREATMENT OF BURNS.

DR. MEURISSE speaks very highly of goldbeaters' skin as an application to burns (*Medical Record*, December 5, 1885). He says that it never becomes adherent to the skin as other forms of dressing do, the pain and inflammation are much less marked, and the wounds heal much more rapidly. The goldbeaters' skin may be washed with cold water at each dressing, and can be used again and again. The liniment or other applications may be made directly to the skin and covered with the tissue. The same substance may be used in dressing blisters after the application of a vesicatory.

#### THE TREATMENT OF RHUS TOXICODENDRON POISONING.

DR. SILAS HUBBARD reports in the *Peoria Monthly* for November that he has often obtained good results in the treatment of rhus toxicodendron poisoning by the application of a strong infusion of stramonium-leaves.

#### OPIUM-POISONING THROUGH MOTHER'S MILK.

MR. WILLIAM T. EVANS reports in the *British Med. Jour.*, December 19, 1885, a case of a newly-born nursing infant which was fatally poisoned by opium given to the mother for after-pains.

### THE OIL OF GAULTHERIA.

BY DRs. H. C. WOOD AND HOBART A. HARE.

THE use which has been made of the oil of gaultheria in rheumatism has been apparently attended with so much advantage that we have been led to make a study of its action upon the animal organism, directing our attention, first, to the symptoms which it produces when given in large quantities by the stomach; then to its effects upon the respiration and circulation; and, finally, its fate within the organism, and its relations with salicylic acid.

When a large dose (one to two fluidounces) of the oil of wintergreen is given to a good-sized dog by the mouth there appear at once great restlessness and discomfort, and an evident nausea, and finally vomiting. There is evident pain in the belly, the walls of which are retracted and hard, a constant desire for water, which keeps the animal standing with its head over a bucket of water, out of which he occasionally attempts to take a sip, which is no sooner done than his discomfort seems to be increased, probably because of the burning sensation produced by the cold water coming in contact with the volatile oil.

Following this there is impairment of power, chiefly in the hind legs, the movements in these members being incoordinated and

clumsy. The animal now lies down, and then, seemingly propelled by an excessive thirst, rises with difficulty and goes to the water, of which he takes no more than he did before. All the symptoms show the presence of acute gastritis.

In one experiment the oil was given at 2.10 P.M.; the vomiting occurred at 2.30, but the matters vomited did not possess as strong an odor of the drug as might have been expected.

At 3.40 P.M. general violent convulsions came on, lasting some minutes, and ending in the dog lying on his side and going through a series of running movements. At 3.45 the breathing was 122 per minute and very labored.

At 4 P.M. the dog got up and walked to the bucket, and stood over it, but in an instant lay down without drinking. He was pushed with the foot to make him get up, struggled a moment, then went into violent general convulsions as before, followed by running movements. The convulsions seemed to be spinal in origin, without unconsciousness. At 5 o'clock the dog died in wild convulsions, having had almost continuous convulsions for over half an hour.

When small doses (16 m. or 1 c.c.) of the oil are injected into the jugular vein of a dog they seem to produce little if any effect, either in the respiratory or cardiac movements. There is no change of any consequence in the pulse-rate or arterial pressure, and unless the dose be given very rapidly or in larger amount the respiratory conditions remain almost unchanged. If the amount of the drug injected be now increased to 2 c.c. or 3 c.c. (30 to 50 m.), the effects are more marked.

No sooner has the drug been fairly injected into the jugular vein than the dog becomes restless and his respirations fuller and more rapid, while the arterial pressure is slightly decreased. The pulse-rate is, however, slightly increased. This condition lasts for three or four seconds, and is followed by a return to almost normal on the part of the respiration, while the arterial pressure is greatly increased over its normal height before the injection.

The return to normal is, however, only of a few seconds' duration; the rapid respiratory movements and the decrease in pressure and increase in pulse-rate return, to last for a slightly longer or shorter time, as the case may be.

In the normal dog the injection of thirty to fifty minims of the oil of gaultheria produces, therefore, a series of cycles, in which there is a marked increase of respiration and decrease of arterial pressure, passing gradu-

ally into normal respiration and normal arterial pressure, to be succeeded after a time by a new cycle of change. In order to determine whether the respiratory phenomena were the result of some action on the peripheral fibres of the pneumogastric or were due to a centric influence, we experimented upon dogs in which the vagi had been cut previous to the injection of the oil. Under these circumstances it was found that the alterations of respiratory rhythm are much more pronounced than in the uninjured animal. The change from the very slow distant respiration of divided vagi was colossal. At the height of the paroxysm the respiratory rate, which before the giving of the oil had been 4 per minute, rose to 288 per minute. After the rapid respiration, during the period of slow breathing, the respiratory rate fell to 12.

The respirations during the period of rapidity seemed to be almost as full and deep as at any time. The cycle of respiratory change from the beginning of one paroxysm of rapid breathing to the beginning of the next varied considerably in length. Sometimes it occupied one minute, in other instances several minutes. Towards the last of the experiment the respirations gradually became more and more slow, but persisted for about one minute after the cessation of the heart's action. These experiments seem to prove that the oil of gaultheria acts directly upon the respiratory centres as a very powerful but peculiar stimulant.

It will be seen that the phenomena resembled somewhat those of the so-called Cheyne-Stokes respiration,—a form of breathing concerning the philosophy of which there are many theories, none of which to our thinking are thoroughly satisfactory. It is well known that when the spinal cord is under the influence of strychnine, alternate periods of furious convulsive discharges of nerve force from the spinal cells alternate with periods in which the relaxation is so extreme that we can well believe the tone of the muscles is below the normal. A possible explanation of the respiratory phenomena of gaultheria-poisoning is, that the condition of the respiratory centres is similar to that of the spinal cord under the influence of strychnine, and that the rapid breathings represent a respiratory convulsion, the slow breathing respiratory relaxation, and that the drug must be considered a respiratory stimulant.

The respiratory influence of this drug is so great that it probably dominates the action upon the circulation, and we therefore made

PLATE NO. 1

experiments upon curarized dogs to determine the influence of the oil of gaultheria upon the circulation, when by artificial means the respiratory function is uniformly maintained. If, under these circumstances, the oil of gaultheria be injected into the jugular vein in doses of thirty to fifty minims, there is an immediate and very decided fall of the arterial pressure, which lasts for thirty or forty seconds, when it is followed by a rapid rise, which continues until the pressure is much beyond its original condition. There seems to be now no rhythm of arterial pressure like that which occurs in the normal dog after the injection of the oil, and we therefore must conclude that the phenomena which we have noted in the normal dog are chiefly secondary to the disturbances of respiration.

These changes of pressure may be found in the following experiment, which we have confirmed by repetition.

*Experiment 1.*—Weight of dog, 30 pounds; small doses of gaultheria; dog curarized; pneumogastrics entire.

Time.	Drug.	Press.	Pulse.	Remarks.
3.20.50	Oil 1.5 c.c.	90-80	138	
3.22	.....	60	210	
3.24	.....	70	186	
3.25	.....	88	150	
3.27	.....	120-130	180	
3.29	.....	140	198	
3.31	.....	140	198	
3.33	.....	160-164	156	Art. resp. appar. broke down.
3.35	.....	220-260	54	

In order to determine the cause of the fall of the arterial pressure in the first part of these experiments, and the subsequent rise of pressure, we cut the spinal cord in the upper cervical region of a powerful dog, maintained artificial respiration, and then injected the gaultheria. The result is expressed in the following experiment.

*Experiment 2.*—December 26, 1885; very large dog; weight, 32 pounds.

Time.	Drug.	Press.	Pulse.	Remarks.
3.30	.....	.....	.....	Cut cord in upper cervical region; artificial respiration.
3.37.50	.....	46	198	
3.38	3 c.c. oil	46-50	192	
3.38.20	.....	.....	.....	Injection ended.
3.38.40	.....	44-50	162	
3.39	.....	40	204	
3.39.05	3 c.c. oil	40	186	
3.42	.....	26	.....	No pulse; dog dead.

This experiment shows that the fall of the arterial pressure in the beginning of the first

experiment, as well as the subsequent rise of pressure, were produced by an action in the vaso-motor centres, since neither of them occurred in Experiment 2, although the amount of the oil of gaultheria per pound of dog was about twice as much as in the previous one. In other words, before paralysis of the vaso-motor centre 1.5 c.c. of the oil of gaultheria caused a great fall and rise of the arterial pressure, whilst after paralysis of the vaso-motor centre 3 c.c. had very little effect. In order to show the little effect which the first 3 c.c. of the oil of gaultheria had, after section of the cord, the following tracings, showing the actual heights before and after the injection, are given.

TRACING NO. 2. Before injection.

TRACING NO. 3. After injection.

The large size of the pulse-wave on Tracing No. 3 shows how little effect the 3 c.c. of oil of gaultheria had had upon the cardiac force.

We have already shown the powerful stimulating influence which this drug has upon the respiratory centres, and the later experiments which we have just discussed show that it is also a powerful vaso-motor stimulant.

The characters of the convulsions in the dogs poisoned with it (given by the mouth) indicate that they are spinal. We have not positively proven this, but it appears as though the spinal cord was also stimulated by the oil.

The dogs poisoned by the mouth died largely on account of the local effects of the drug upon the gastro-intestinal mucous mem-

brane and of its influence upon the nerve-centres, but when the dog is killed by intravenous injection of the oil the heart is paralyzed before respiration ceases, although at the same time it is remarkable how considerable are the individual pulse-waves when the pressure is almost at zero.

The results of our experiments upon the lower animals may be summed up as follows: In large doses, oil of gaultheria acts as a powerful irritant to the gastric mucous membrane, producing violent gastritis, with excessive vomiting, but in our experiments without purging. It is a stimulant of great power to the respiratory centre and to the vaso-motor centres, and probably also to the motor centres of the cord; in sufficient amount it acts as a paralyzant to these same centres. Upon the heart it exerts a paralyzant action, only apparent when very large amounts of it are in the blood, and very feeble when compared with that of most other volatile oils.

Very few cases of human poisoning by this drug have been put on record, and, briefly stated, they are as follows:

In the *Philadelphia Medical Examiner* for June, 1852, p. 347, Dr. T. J. Gallaher reports the case of a boy, æt. 9, who swallowed at least half an ounce of the oil. Shortly afterwards he ate some supper, after which he vomited freely, with a good deal of retching. There was great irritability of the stomach and all the symptoms of acute gastritis. His skin was hot; pulse, 125 per minute. Consciousness was retained. The respirations were very slow and laborious. There was marked dulness of hearing. Perfect recovery was reached in about two weeks.

In the *New York Medical Gazette* for 1867, p. 380, Dr. Juvet reports the case of a farmer, æt. 55, who, by accident, drank about half an ounce of oil of wintergreen of his own distilling, and therefore not very pure. He no sooner discovered his mistake than he said he would die, and refused to send for a doctor, saying that it would be a useless procedure. He drank large quantities of milk and eggs, and swallowed an infusion of tobacco in order to provoke vomiting. When the doctor at last arrived the patient's mind was perfectly clear, and he described how the occurrence happened very clearly. He suffered from severe pain in the stomach and hypochondrium, accompanied by an intense thirst, and "a kind of death sinking." He was perspiring very profusely. He said all things looked green, and this perversion of sight

finally deepened into blindness. His mind was yet clear. In a short time he lost consciousness, gradually his mind wandered, and he became comatose. An hour after this he died without a groan.

In the *New York Medical Journal* for 1875, p. 602, Dr. A. McL. Hamilton gives the history of the following case: A woman after taking a dose of cod-liver oil swallowed about half an ounce of the oil of wintergreen, being unaware of its properties. She complained of dizziness and drowsiness in the course of an hour, and this was followed by marked delirium. An emetic was given, and she vomited freely. Her pupils were contracted. Her extremities were cold, and her respirations were labored and quick. She complained of intense cerebral pain, and "noise in the ears" like the "buzzing of bees." She also had disturbed vision when she was not delirious, and also hallucinations of sight and of hearing. She had an irresistible desire to sleep, and was only prevented from doing so by the use of strong currents of electricity. A peculiar condition was a hemiparesis of the left side, with a notable loss of power.

Beck, in his work on "Medical Jurisprudence," mentions the cases of six soldiers who drank a tea made of andromeda, gaultheria, and ledum, and who suffered from vomiting, cold sweat, vertigo, and weakness, and one of them became insensible. These cases were hardly those of pure and simple oil of gaultheria poisoning.

The only symptom which we have seen produced by the largest therapeutic doses of oil of gaultheria have been those of mild cinchonism, or, in other words, those which are produced by therapeutic doses of salicylic acid.

Dr. N. A. Randolph and Mr. S. G. Dixon, of the University of Pennsylvania, found that the oil of gaultheria is readily absorbed when applied to the skin, or when inhaled from a sponge held in such a way that it did not touch the surface of the lips and chin, and that it appeared in the form of salicylic acid in the urine from forty to fifty minutes after the inhalation was begun.

We have experimentally confirmed this liberation of salicylic acid in the human system. The question arises whether all of the ingested oil is changed into the acid. To answer this question the following tests were made: One thousand cubic centimetres of the urine of a man who was taking 10 minims every three hours of the drug was distilled; another thousand cubic centi-

metres was shaken with sulphuric ether, and allowed to stand. As soon as the ether had thoroughly separated it was pipetted off and filtered, for the purpose of getting rid of the mucus and phosphates. In neither examination could unchanged oil be discovered. We next treated with ether, in the manner just described, one thousand cubic centimetres of the urine of a patient who was taking 200 minims a day of the oil, and failed entirely to discover a trace of unchanged oil. It must therefore, we think, be concluded that therapeutic doses of oil of gaultheria are entirely changed into salicylic acid in the system. Analogy certainly indicates, however, that when large toxic doses of the oil are taken a portion is altered in the system and a portion allowed to escape unchanged.

As the oil of gaultheria appears to act upon the system in the same manner as does salicylic acid, it becomes a matter of interest both practical and scientific to determine the equivalent doses of the two, or, in other words, how much of the oil we must administer to get the effect of a given quantity of the acid. About ninety per cent. of the oil is composed of the so-called methyl salicylate, having the formula  $C_7H_5O_2CH_3$ . This methyl salicylate is a substitution compound in which one atom of the hydrogen of salicylic acid has been replaced by a molecule of methyl,  $CH_3$ . The formula of salicylic acid is  $C_7H_5O_2$ ; of methyl salicylate,  $C_7 \left\{ \begin{smallmatrix} H_5 \\ CH_3 \end{smallmatrix} \right\} O_2$ .

In the animal system it would appear that one atom of carbon and two atoms of hydrogen in the methyl are removed by oxidation, and  $C_7 \left\{ \begin{smallmatrix} H_5 \\ CH_3 \end{smallmatrix} \right\} O_2$  becomes  $C_7H_5O_2$ .

Now  $C_7 \left\{ \begin{smallmatrix} H_5 \\ CH_3 \end{smallmatrix} \right\} O_2$  has an atomic weight of 152, while the atomic weight of  $C_7H_5O_2$  is 138; so that the administration of 152 grains of the methyl salicylate ought to be equivalent to the giving of 138 grains of salicylic acid.

As 169 grains of the oil of gaultheria contain 152 grains of the methyl salicylate, they should be equivalent to 138 grains of salicylic acid.

#### ACUTE YELLOW ATROPHY OF THE LIVER.

By JOS. X. ZITEKE, M.D., BATESVILLE, IND.

THE yellow atrophy of the liver is proportionally one of those rarely-recognized diseases of which but few records compara-

tively come down to us in medical literature, if compared with those about other maladies to which human flesh is heir. Still, it appears to me that in reality the disease is not so rare as it seems, and that many cases which came to the observation of the physician were sometimes either misunderstood, ignored, or falsely classified, so that the profession in general is virtually obliged to rely chiefly upon those cases which were observed in the clinics of large hospitals, or upon those which were reported by the most prominent men of the profession as having occurred in their practice.

And, in fact, if we consider the general and particular symptoms of this dangerous—indeed, often fatal—disease, which in their first stage creep slowly in without any special characteristic signs, often even assuming the well-known features of other less dangerous pathological processes; further, if we reflect how seldom it is possible for a small town or country practitioner to confirm his diagnosis by a pathologico-anatomical dissection, it is hardly to be wondered that many a case of acute yellow atrophy of the liver is wrongly diagnosed and falsely classified in the statistical reports of the country.

In spite of this fact, however, the disease seems to have been well known to the fathers of medicine, for not only did Hippocrates and Galen classify it as a disease *per se*, but even many of the monastic authors of the middle ages, who practised extensively both medicine and surgery, bear testimony to its existence, its widely-separated nature from other diseases of the liver, and its rapid and deadly termination.

It was a great and not uninteresting surprise to me to find Albertus Magnus, the great Dominican naturalist, mention the disease in his extensive work, "De Naturalibus." He says as follows: "Ante omnibus est antem quidam morbus Hepatis, etsi aliquando consecutus Ictero tamen valde differens a consuetis morbis ejusdem organi; morbus valde periculosus vitæ, et propter cursum celerimum, et propter febrim acutam cerebri, ipsum terminantem. Videtur autem doctis in medicina, hepatem in isto morbo, aut naturam, aut accidentia mutari, aut in forma ipsa transformari." (*De rebus Natural.*, vol. ii., Augsburg edition, 1585.)

A similar opinion is also expressed in a work of later date, written by Archbishop Albik, M.D., of Prague, physician to the German Emperor Wenceslaus IV. Here also the disease is considered as a special disorder

of the liver, dangerous on account of its rapid course and violent brain fever. (*De morbis corporis humani Magistri Albici, professoris medicinæ in Univers. Pragensi, 1495.*)

Similar testimonies can be found in the writings of French and Italian physicians of the following centuries (see Verceloni, Baillou), who described the disease as a special and "*Inæ naturæ forma Icteri*," and who again were followed by other writers of the same opinion, till in the first two decades of our century the general attention of the profession was attracted to its study by the master-works of Abercrombie, Brien, Alison, and Bright.

Later, Budd and Rokitsansky treated of the same subject, till finally Frerichs, Liebermeister, and Klebs made the disease a subject of general discussion in the profession. Nevertheless, in spite of the many eminent men engaged in the study of this malady, no positive, final, and decisive judgment was rendered, partly because some considered it as a mere local disease of the liver, whilst others considered it a mere symptom of a general constitutional malady of the whole organism.

During a practice of more than ten years there came but two cases of this disease under my observation, and these I dare to submit to the general consideration of the profession, conscious but too well of the dangerous ground upon which I am treading:

CASE I.—Mrs. A. M., married, mother of three children, 32 years of age, middle size, black eyes and hair, sallow complexion, firm bones, moderately well nourished, wife of a farmer in Spencer County, Indiana, born in Southern Germany, called to consult me in the year 1876. According to her own statement she remembers to have been sick but three times during her whole life; twice during the time since she was married. In her first sickness she suffered from cough, pain in the lower portion of the right side of her chest, had difficulty in breathing, was constipated, had no appetite, and her face and skin became of quite yellowish, dirty color. Was treated by a country doctor, who considered her case a consumption, and gave her many remedies, but without any relief. Finally she went to Cincinnati to consult Prof. Reamy. She remained in the city for six weeks, and returned home cured. She does not remember what the doctor called her sickness, but she was positive that he said there was no consumption.

From that time on she felt well till she became once more pregnant. At that time all

the former symptoms reappeared, and grew worse the further she progressed in her pregnancy. She had taken many remedies again, but without any benefit.

Finally she was delivered of a sound child. The labor was slow, tedious, and painful. But the physician who attended her was in no hurry, and left well alone. Hence she was delivered of a girl baby without any instruments, and with but little internal medicine, which the doctor gave her after the birth of the child.

Her recovery was very slow and very incomplete. Her bowels were yet constipated, and her skin still a little yellow. Finally she determined to start for Cincinnati again, when one of her many sympathetic friends gave her a bottle of a patent medicine which a peddler left at her house, and which promised on its label to cure nearly all the ills to which human flesh is, and ever will be, heir. She took several doses of the medicine, which purged her quite acutely, and after a few weeks of self-treatment she felt better, and the yellow color disappeared from her face.

At present the patient is again pregnant, and, according to her reckoning, in the fifth month. Her pulse is weak, her tongue covered with a dark yellow crust; her appetite is good, but she cannot eat, as she has great pain in her stomach after taking nourishment, and if she eats in spite of it she throws the food up quite undigested. Auscultation and percussion reveal dulness about a half-inch below the right costal arch, and dulness in the lower portion, on both sides of lesser curvature of the stomach. Sounds of the heart normal. The urine is spare and of dark color. Chemical test reveals but little of albumen, no sugar, no blood, no leucin nor tyrosin, but biliverdin. Specific gravity 1.027. Reaction decidedly acid. The pulse changed its type three times within one hour she stayed with me. Sometimes it was weak and thready, again it became quick and double-beating, and again very slow. The changes in the pulse can be seen on her face, which flushes at times, and resumes again its yellow dirty tint.

Further, she states that towards the evening her face begins to flush, and that many days in succession she cannot sleep on account of headache in the temporal and parietal region.

The expression in her eyes corresponds to the change observed in her pulse. At times they become quite wild and fiery, at other times they seem dull and have a far-away expression.

The bowels were constipated for days, and no pills could regulate them. She took as much as ten pills at once, and though she had three or four evacuations next day, they became as obstinately inactive within the next forty-eight hours. And again she would be constipated for three or four days, when suddenly diarrhoea would set in, last for a day or two, and be followed again by constipation.

As to her genital organs, they were normal; no prolapsus, no version or flexion to be detected. No sensitiveness in the ovarian region. At times of her menstrual period she used to be sometimes troubled with leucorrhœa.

Such was the *status præsens*. As to diagnosis, I cannot say that I was able to settle the matter with myself satisfactorily. I saw that there was a liver-disease here,—but which, that was the question. However, the continual use of nitro-muriatic acid internally, and of podophyllum, exchanged sometimes for hydrarg. chlor. mite, produced on her quite a beneficent effect, and after six or seven weeks, during which she was rapidly improving, I lost sight of her.

One important fact, however, I cannot pass over, namely, that whilst examining her carefully it seemed to me that her pregnancy was further progressed than she thought, and that the menstrual flow which she professed to have seen some four months ago may have been one of the unsure and ever-vacillating will-o'-the-wisps which deceive many a pregnant woman as to her real state.

Some five months later Dr. W. called on me, with the request to accompany him to a sick lady whom he had delivered some eight weeks previously, and who had afterwards contracted puerperal fever, from which she had recovered about eight days ago.

According to his statement the labor had been long and tedious, and, as the patient was growing weaker every moment, he thought it necessary to terminate it by the use of the forceps. About forty-eight hours after the birth of the child the first symptoms of puerperal fever set in, though no antiseptic precaution—*i.e.*, as it was used in those days—was neglected.

During the whole length of the fever he and another physician of the village had attended upon her day and night, and both of them proclaimed it as one of the most severe cases from which they had seen a woman recover. Indeed, it seemed strange that a woman who had suffered so long and so much during her pregnancy should have resisted the deadly attack of a fever to which many

hundreds of stout and robust women fall victims.

Since the last few days of her recovery, however, another set of symptoms appeared, which caused considerable alarm both to the friends and the attending physicians of the sick woman. It was for this reason that the doctor wished me to see the sick lady with him. The history of the case, as given by the doctor, was as follows:

It was about on the fifth day of her convalescence that shortly after dinner she was seized with nausea, which was followed by a copious vomiting. After the ejection of the nourishment a quantity of dark-greenish fluid followed, which formed a brownish sediment in the vessel. Two rather watery evacuations of the bowels followed a short time after the vomiting, of very pale color, and mixed with numerous kernels of the same dark tint. At the same time she complained of great pain in her head, was restless and excited, and again stupidly quiet. Spasmodic contractions both of the lower and upper extremities were noted.

Such were the symptoms given to me on our way to the patient. The *status præsens*, as observed by me, was this:

The patient was lying in a comatose state, from which, however, she awakened from time to time, and uttered a kind of inarticulate or again piercing cries. The skin was dry, of dark color, as well as the conjunctiva bulbi.

The pulse was irregular and weak; very quick, 156 per minute.

The tongue was coated with a dark fleshy fur; also her lips and the mucous membranes around the frænulum labii inferioris were covered with similar sordes.

The temperature was 104.5°.

The urine was of dark wine-color, with a similar sediment. Chemical test revealed no albumen, no sugar, but biliverdin and tyrosin.

Pectoral examination revealed bronchial fremitus, whilst the dulness over the lower portion of right sternum was nearly gone, but could be observed at the back, about one and a half inch from the spinal column.

Such was the state of the patient. My diagnosis was atrophica hepatis acuta. Prognosis, death.

Twenty-four hours after this my first visit to the patient, whilst on my way to see her again, I heard that she was dead. Yet as she had been about four days ago on a fair way to recovery, her husband, a bright German, gave a willing permission for a pathologico-

anatomical examination of the chest and upper part of the abdomen of the body, which examination was performed the same evening.

The most important facts detected were these:

Lungs show signs of recent bronchitis. Heart normal. Liver sunk back near the spinal column and covered with the bowels; considerably diminished; of soft and yellowish color; the capsule ragged.

The gall-bladder filled with a greenish fluid; also the ductus choledochus and the neighboring portions of the small intestines. The mucous membrane of the lower portion of the intestines covered with dark reddish patches (hemorrhagic ecchymoses, or what the French call *plaques hemorrhagiques*).

The end of the colon transversum and descendens were filled with a whitish, hard mass of excrement, some portions of which, however, were of light yellow color.

In the stomach, near the pylorus, were the same hemorrhagic metamorphoses and yellowish fluid.

The spleen was enlarged, of whitish tint and soft consistence.

The kidneys soft and shrunk together, and in some portions degenerated.

CASE II.—S. W., 37 years old, male, of German parentage, born in Pennsylvania. Entered the army when eighteen years old, and served to the end of the war. His bodily build was strong and muscular, and a little inclined to adipous formation. After the war he married and opened a saloon. Says that he was never sick before, except once whilst in the army, where he had contracted a hard chancre, which was followed by inflammation of the inguinal lymphatics. Some time after the cure of the local evil he was attacked by a kind of rash, which appeared on his extremities and chest, for which he underwent treatment by the old German method of mercurial inunctions. After eight such inunctions he was cured. Since that time he had been always well, had two children, one of which died from some brain-trouble. The other is alive and healthy. Like nearly all German-Americans, he was a drinker, but with a decided relish for whiskey, which he preferred to the beer of his fathers.

His present trouble dates back about fifteen months, when he acquired what he called dyspepsia. He could not digest his food, and was troubled with vomiting, chiefly after breakfast and dinner. Had pain over his stomach, and often an internal griping pain,

which began below the os xyphoideum and spread all over the abdomen, from which it would sometimes even go into his feet, producing a painful crampy sensation.

His dyspepsia continued to trouble him more and more, and, though he professed to have used all kinds of drugs prescribed by doctors and advised by friends, he grew worse rather than better. Since some months his bowels became decidedly inactive; his ejections had a very bad smell, and were of whitish color. The taste of his mouth, chiefly in the morning, was quite sickening, so that he could not help vomiting. His tongue and lips were coated by a kind of brownish rash or fur. The conjunctiva bulbi had a slight yellow tint; the eye itself a dull and melancholic expression.

The results of a physical examination were as follows: The lungs revealed in the apex of the right lung bronchial breathing and slight crepitus, resembling the râle muqueux; the heart normal. Stomach bloated, enlarged, yet quite elastic on pressure; no strong pain. Liver enlarged about half an inch over the costal arch; spleen in the same condition, and very sensitive to the strokes of the percussion-hammer. Pain in the back corresponding with the frontal hepatic region, and going up to the angle of the scapula.

Pulse full and quick, 95 per minute.

Urine not examined.

He was told how necessary it was for him to abstain entirely from all alcoholic drinks, and was put on a treatment by nitro-muriatic acid, and in order to regulate his bowels a mixture of iris vers., taraxac., and podophyl. was given.

He returned about two weeks later in an improved condition. The same treatment was continued, and the same advice repeated as a *conditio sine quâ non*.

Eight weeks after his second visit, the icterus had entirely disappeared, the bowels became active if not regular, and the patient was dismissed with the same advice as given before.

About six months later I was called one evening to his house, the messenger reporting him very bad; in fact, he was not expected to live. The miserable habit of years, which was digging his very grave some months ago, had again prevailed upon him, and in spite of his knowledge of the consequences he indulged in it freely. The promise he had given me to sell his saloon he had never kept, or perhaps never intended to keep at all, for there are yet some men so stupid who consider it a good joke to lie to their physician, as if a man

could commit a greater foolishness than to speak untruth to his doctor or to deceive his wife.

Having thus fallen back to his daily drink of whiskey, the dangerous symptoms returned one by one, but in another form and intensity, and in spite of pepsine, lacto-pepsine, gentian and rhubarb, colocynth and mercury, administered by a friendly physician and fellow-drinker, they became worse and worse, till they confined him to bed. The period in which the first symptoms appeared again to the day when he took to his bed was about ten to fourteen days.

*Status præsens.*—The patient had evidently lost flesh; he was still a muscular man, but his powerful, bony frame was all that struck the eye of an observer. His skin was of slightly yellowish color and entirely dry, hot dry, so well expressed in the *chaleur mordant*. The tongue was coated with a brown-blackish fur, forming nearly a membrane all over the tongue and lips. His breath was sickening; indeed, the whole room was full of a nauseously offensive smell. From time to time he was subjected to pain in the stomach, and then vomited a yellowish watery fluid, which formed a brownish sediment in the vessel. The smell of the vomited matter was decidedly acid.

His bowels were again constipated, and though he had taken the previous night ten Ayer's pills, he had no operation till an injection, consisting of sulph. mag., ole. rici, and a little ol. terebinth., was given.

He complained of excruciating pain in his head, chiefly in the temporal and occipital region, which went down like a knife to his neck and back. There was also evident twitching in the muscles of the lower extremities and abdomen. Sometimes he fell into a kind of stupor, from which he awoke in a few minutes shrieking and talking the wildest nonsense.

The abdomen was bloated and very painful to pressure. The pulse was 140 per minute. Temperature, 105°. The heat was characteristically dry.

The urine contained very slight traces of albumen, but large quantities of leucin, also cholic acid; specific gravity, 1.027; reaction acid. The sediment in the chamber-vessel was of green-yellowish color.

Auscultation: percussion gave evidence of a chronic bronchial catarrh of the lungs, a normal heart, but the hepatic dulness considerably smaller than before. Pain very severe on pressure.

The abdomen and lower extremities were covered with about ten large petechial spots resembling roseola of typhoid fever.

Such was the state of the patient as found that evening, and such it remained for the next two days,—*i.e.*, till his death.

Though it was possible to procure him some ease by a copious evacuation from his bowels, of a clayish hard, and later, yellowish, sticky substance, though the frequency of the vomiting was also diminished and his temperature lowered to 101°, yet it was impossible to keep it down; even in spite of the increased doses of antipyretics it reached shortly before his death 106°.

The delirium continued steady for the whole two days, and on the third—*i.e.*, the day of his death—it gave place to a comatose stupor, from which it was impossible to arouse him.

The icterus grew darker in shade, and after death became more of a green than of a yellow hue.

Several hemorrhagic spots were found upon his back.

No post-mortem examination was made, as his wife would not allow it.

My diagnosis was atrophica hepatis acuta, based chiefly on the vomiting, the great headache, the restlessness, somnolence, and finally the delirium, accompanied by spasmodic twitching in the extremities and abdomen.

The changeable pulse, the dark fur covering tongue and lips, the leucin and cholic acid in the urine, the diminished hepatic dulness, all this speak for my diagnosis, whilst the steady high temperature for three days, and perhaps longer, seems to be quite out of the common.

It is, therefore, relying chiefly upon the symptoms enumerated, that I based my diagnosis, and for that very reason I do not submit it to the profession with a self-important and conscious *magister dixit*, as seems to be a fashion of our days, but trust it to the kind criticism and private judgment of each member of the profession.

However different from each other these two cases may have been, they contained still both some symptoms which, in themselves, must necessarily attract the attention of every judicious physician.

1. A previous or several times repeated icterus, which was the precursor of the fatal illness in both cases, though more than four months in the first, whilst about seven months intervened in the second case.

2. The gastric symptoms, which very often

are considered as dyspeptic, chiefly in drinkers and in malarious districts.

3. The color, test, and specific gravity of the urine, and above all the presence of tyrosin in the first, and of leucin and cholic acid in the second, case, which are hardly ever found in another kind of liver-disease, but which are always, either one or both, present in the acute atrophy of the liver. (See Freichs, Collingworth, Rokitsansky, and Klebs.)

#### ON THE TREATMENT OF HEMORRHAGIC MALARIAL FEVER.

BY DR. R. H. DAY, BATON ROUGE, LA.

**I**N recent years much has been written about malarial hemorrhagic fever, or malarial hæmaturia, and its treatment; but so discordant is medical opinion as to its essential nature, and so diverse the plans of treatment recommended, that to-day the disease and its treatment are shrouded in confusion and uncertainty.

I shall limit myself in this short paper to its treatment only, premising, however, that unless a correct knowledge and comprehension of its real nature, and the pathological changes wrought in the system by it, be had, its treatment must remain vacillating, uncertain, and empirical.

Having, from my first entrance into the medical profession, been thrown into highly-malarious districts of country, it was my fortune early in my medical career to become familiar with this most terrible disease, both in its mild and most virulent forms. What I have to say, therefore, about it is predicated upon a long, personal, and practical experience, and will have, at least, the merit of freshness and personality.

I think the chief obstacle in the way of its correct treatment consists in the fact that it is too commonly looked upon as a disease primarily of the kidneys, and the other lesions as secondary thereto; whereas it is emphatically an hepatic and blood disease of malarial origin, no case ever occurring except in persons presenting in the most marked and expressive manner the evidences of unmistakable malarial toxæmia. How the malarial poison acts upon the human organism to bring about these pathological changes it is not my purpose now to investigate, but simply allude to them to make the course of treatment which I have found most successful rational and intelligible to my readers.

As a matter of course, the treatment must somewhat vary according to the stage of the disease when first seen, and to the type of the disease, whether mild or of a grave form; for it must be borne in mind that, like all other diseases, it has its different grades of severity or types. If the disease is mild in its outset, characterized by decided intermittence in its symptoms and the presence of red blood-corpuscles in the urine, or, what is sometimes the case, the hemorrhage is from the bowels instead of by the kidneys, it will indicate that the blood is less profoundly altered, and we may confidently expect an easy triumph over the disease. Here a few small doses of calomel combined with opium and bicarbonate of sodium to stimulate the biliary secretions, followed by efficient doses of quinine, will very promptly break up the chain of morbid actions and place the patient in a state of convalescence. When, however, the type of the disease is grave and violent, which is more often the case, the stomach will be greatly nauseated, with frequent retching and vomiting of a greenish fluid filled with mucous flocculi, the pulse small and feeble, skin cool or cold, with pronounced chill or shivering and frequent emissions of bloody urine, apparently (really) disintegrated blood, destitute of any red blood-corpuscles, but abounding in the debris of the decomposed blood. Under these conditions we have no time to parley. Here decision and promptitude must mark our course. We must at once apply over the epigastrium and liver a blistering plaster, give a hypodermic injection of morphine, from  $\frac{1}{4}$  to  $\frac{1}{2}$  gr., and repeat after one or two hours. If the stomach is not quieted and reaction established, give 3 to 5 grs. of calomel with bicarbonate of sodium every two to three hours till enough has been retained to act with certainty upon the liver (generally 15 to 20 grs. suffice). If the calomel does not move the bowels after a reasonable time, say four to five hours after the last dose of the mild chloride, administer enemas of warm water containing a tablespoonful of camphorated oil every hour or two till the bowels have been gently evacuated. If the stomach is still troubled with nausea, give a drop of creasote, made into an emulsion with bicarbonate of sodium and a small quantity of morphine, with aqua menthæ every one or two hours *pro re nata*, and as soon as a bilious discharge has been had from the bowels or reaction established, commence with quinine, either by the stomach or by hypodermic injection, in from 5 to 10 gr. doses, for its specific effect in counteracting or ar-

resting the malarial toxæmia, and push it to its systemic manifestation; generally from 30 to 50 grs. will be quite sufficient. As soon as the function of the liver is restored or appreciably aroused, and enough quinine has been introduced into the system to make its physiological effect manifest, commence to give the muriated tincture of iron in full doses, 20 to 30 drops every four hours, with the object of toning up the debilitated blood-vessels, reconstructing and vitalizing the hæmoglobin and red blood-corpuscles, thus endeavoring to restore the normal and vital condition of the blood.

If the kidneys should fail to act or work feebly, frequent frictions over the back, with a liniment composed of spirit of turpentine, tincture of digitalis, and whiskey rubbed in warm, will often be found efficient in stimulating them to action. Sometimes the administration of spirit of turpentine inwardly in 3 to 5 drop doses may be needed to supplement the liniment frictions in hastening the resumption of functional activity of the kidneys.

Such have been my guiding principles and course of treatment of this disease; and so well satisfied am I with the results that I can with confidence commend the same to any physician who may encounter in his practice this very serious malady.

#### ON THE TREATMENT OF SCIATICA AND NEURALGIC AFFECTIONS BY CONGELATION WITH METHYL CHLORIDE.

BY HENRY B. MILLARD, M.D., A.M., ETC., NEW YORK.

DR. J. M. Debove, of Paris, in the *Gazette Hebdomadaire*, August 15, 1884, described a method of treatment, first employed by himself, of various neuralgic affections, particularly sciatica, by the local application of the chloride of methyl (*not methylene*). I have seen various accounts in medical journals of this method, but most of them very brief, and none of them indicating a real knowledge of it.

Being in Paris the summer of 1884, when Debove first employed this treatment, I passed considerable time with him at the Hôpital des Tournelles (Hôpital Andral), of which he is the physician-in-chief, and at the Hôtel Dieu, where he was temporarily filling the place of Dr. Germain Sée, observing the effects and method of treatment.

Dr. Debove in the article above referred to says, "Revulsives appear to act in sciatica in

exciting the nervous extremities of the affected nerve, but the number of nerve-filaments excited is always limited; it is impossible indeed to apply a blister which extends from the hip to the calcaneum, or to cauterize the entire surface of the limb.

"I thought that this revulsion could be obtained in a different form by congealing the skin, for congelation may be effected and the skin regain the integrity of its functions. There seemed no objection to trying this, for the worst accident would be the production of a slough (*eschar*), which in the case I intended to apply it did not seem of great moment, as the treatment of sciatica by the cautery has become classical."

The *chloride of methyl*,  $\text{CH}_3\text{Cl}$ , is a gas which is rendered liquid by pressure. This product is extensively fabricated in Paris by heating trimethylamine, which in its turn is made from the *vinasses*, the spent wash of the stills in which the molasses of the beet-root is distilled in the production of alcohol. It is much used in laboratories for the purpose of producing intense cold, and in freezing pathological specimens. When placed in an open vessel it boils at a temperature of  $-23^\circ \text{C.}$  ( $=-11^\circ \text{F.}$ ). It is not explosive, and in strong cylinders can be transported without danger. In France it is sold at six francs the litre.

Dr. Debove first employed a strong glass siphon, filled from a leaden retort containing the liquefied gas; the liquid is liberated by turning a screw at the top, through a flexible leaden tube with a finely-perforated brass point, by which it can be directed upon the affected part. The liquid on being liberated becomes at once volatilized, and escapes in the form of a very fine spray. Dr. Debove has tried to produce the same effect with a Richardson's apparatus, but ineffectually. Within the last year, Galante has manufactured a strong copper siphon which is absolutely free from danger, as it cannot be broken.

The liquefied gas directed upon the skin produces immediate whitening and hardness by congelation; these two effects disappear almost immediately, the skin becoming red and hot. To quote from Debove: "The jet of methyl chloride is directed upon the skin of the entire region which is the seat of pain, in sciatica from the sacrum to the malleolus." Patients experience a burning sensation, which is painful, but in no wise comparable to that produced by cauterization by heat, nor is it of long duration. No dressing is necessary. Practically, the effect is the same as that of an extensive, superficial, and rapid cauterization

without vesication, or destruction of the epidermis.

I have seen Dr. Debove use it very freely on a part to ascertain if a sphacelus could be produced. He has informed me, however, that he has never known it to produce such a result. The worst effect he has observed, and that but rarely, has been slight vesication. Two or three cases have, however, been reported in Paris where erysipelas followed. Dr. Debove informs me that he is unable to comprehend this, as in his own practice he never has observed any ill effects. It may be that in the cases referred to it was applied to loose tissues, or that the systems of the patients were impoverished.

This treatment is not suited to all forms of neuralgia, as, for example, not to that having a syphilitic origin; it is most applicable to those cases having a rheumatic basis. "My first patient," says Debove, "was affected with sciatica neuralgia, and had been treated in vain for various attacks by the actual cautery, and had not been helped under my service by a month's rest in bed. I applied the jet of chloride of methyl over the entire surface affected, from the hip to the external malleolus. A minute after this patient, who had not been able previously to set his foot to the ground, walked without limping, declaring himself cured. He was quite stupefied by his cure; I confess my own astonishment was not less than his, but I was well aware that marvellous therapeutic results are often a mere coincidence or are due to the imagination, and that further trials on the part of the physician are not always attended with similar success. This is especially true of sciatica which has been cured by the simple cauterization of the lobe of the ear. Thanks to the frequency of the disease in question, I have been able to make further trials, and I can state to-day that the effects of the treatment have been constant and instantaneous.

"I cured the first case three months ago, and up to the present time there has been no relapse. My other patients were either cured at once, or have had light relapses, immediately yielding to the application of the methyl. These patients suffered from simple sciatic neuralgia, of the form known as rheumatic. Their affections had existed from two weeks to three months, and they all suffered so much that they could not put their feet to the ground."

The following cases I myself saw treated, conversing with the patients and examining the records of their cases.

*Hôpital des Tournelles.*—Robert, æt. 49. Sciatica of rheumatic origin of six months' standing. Almost entirely cured by two applications, each one being followed by instant relief.

Male patient, æt. 50. Acute sciatica nearly cured by three applications.

Male patient, æt. 31. Sciatica of fourteen months' standing. Disappeared almost entirely after one application.

Male patient, æt. 50. Intercostal neuralgia of seven months' standing cured by one application.

*Hôtel Dieu.*—Man, æt. 40. Sciatica which has existed about eleven months. Nearly cured by a single application.

Paul Bonvert, aged 30. Sciatica of a year's standing cured by one application.

Thirry, æt. 37. Sciatica for six months. Had been treated by the actual cautery. Cured by one application of methyl chloride.

There were a number of other cases of a similar character which fell under my observation. As to whether what I have designated as a "cure" in these was a radical one I had from my own observation no means of knowing. Dr. Debove afterwards informed me that these cases seemed perfectly cured, though relapses might occur. The effects of the application seemed indeed, in some cases, like extraordinary feats of magic. A patient would be recumbent from pain to such an extent as to make movement of the affected part practically impossible, and immediately after the application of the spray would be able to walk with facility. It seemed to produce local anæsthesia without loss of power. And yet cures of sciatica by a single operation with the cautery or otherwise are possible. I myself have effected them in one or two cases, and one of my patients, a delicate girl, who suffered agony which could be relieved only by almost dangerous hypodermic injections of morphine, was cured by a single application to the sciatic nerve of the galvanic needle.

That the methyl chloride used as employed by Dr. Debove may be of the greatest value I fully believe. Especially could it be made to take the place, in many cases, of the thermocautery. It is less painful, it can be used with greater rapidity, and can be made to cover a large surface.

Owing to the impossibility, thus far, of obtaining the chemical in this country, I have tried to produce the same effect with petrolic ether,—rhigolene. With a Richardson's double bulb I have reduced in three or four minutes the temperature of water in a test-tube to zero,

and in five or six minutes have produced congelation of the surface. This, however, is a very slow process, especially when congelation of a large surface is sought, compared with the chloride of methyl, which almost instantaneously reduces the temperature to  $11^{\circ}$  F. below zero. Aside from the time consumed, the rhigolene does not produce so much blanching of the skin, and the heat and reaction after its use are less.

The cost of the manufacture of the gas and of the siphon here would be considerable. A glass siphon even, properly made, would cost not less than fifteen dollars, in Paris the cost is twenty-seven francs, and is inferior to the copper siphon, which alone, I think, should be used, as being absolutely free from danger.

I present this mercantile aspect of the subject with other details, because I hope yet to see the chloride of methyl extensively employed here. The price of the copper siphon holding two kilogrammes, made by Galante, is one hundred and seventy-five francs; the two kilos. costing twelve francs. The same firm has also constructed a copper cylinder with all the accessories for filling the siphon, etc., holding twenty-five kilos., the price being three hundred and fifty francs. The cylinder and the siphon, each filled, would then cost eight hundred and twenty-five francs. The whole imported here, with duties, etc., would, without allowing any profit to the importer, cost nearly two hundred and seventy-five dollars. So it is apparent, I think, that unless the chemical can be made here, the prospects of its being extensively employed this side the water are not great. I do not despair yet, however, of having its fabrication brought about here.

#### NOTES ON A CASE OF FÆCAL CALCULI.

BY DAVIDSON SCOTT, M.D., SPOKAN FALLS, WASHINGTON TERRITORY.

IN November, 1877, I saw a woman—aged 60, lymphatic temperament, married; occupation, housekeeper; native American—in consultation with the family physician. Had been suffering for two years from jaundice. Had suffered previously from attacks of bilious colic, which had, for the past year, become of daily occurrence. She had been large and fat, but was now much emaciated.

No bile entered the alimentary canal. All the fluids of the body were saturated with it; vicarious elimination was taking place through all the emunctories. The under-garments

were literally dyed with it. It required no great amount of discrimination to diagnose mechanical obstruction of the common duct of the liver.

As I expected, palpation revealed a distended gall-cyst filled with gallstones. They could be felt "like marbles in a bag." Further examination revealed a number of hard bodies slightly movable, and doubtless within the transverse colon. *Diagnosis*: "Mechanical obstruction of ductus communis, due possibly to impaction from gallstones, but more probably to fæcal calculi in that part of the colon where it is in relation to the common duct of the liver." The hard bodies in the transverse colon I felt assured were fæcal calculi.

The patient was ordered to take, if possible, a pint of olive oil daily, to be continued until it produced free catharsis. The treatment was commenced next day, during which she took one-half pint, and on the second and third day thereafter a pint daily. The oil began passing the bowels (undigested, as I anticipated) on the second day, and on the third several fæcal calculi were evacuated, one of which was described as being as large as a walnut. The oil was continued some days without further result. She made a rapid recovery, in three weeks being able to come to my office in the city,—Oskaloosa, Iowa,—riding twelve miles by rail. At this time nearly all traces of the jaundice had disappeared. When last heard from, within a few months, she was still enjoying good health, having had no return of the disease.

#### A NEW POWDER-BLOWER.

BY J. D. KELLY, A.M., M.D., LOWVILLE, N. Y.

THE necessity of applying a medicamentum in the form of powder directly upon affected mucous surfaces is demonstrated repeatedly in every-day practice. In some affections, and under certain circumstances, no measure is so greatly in vogue and so confidently relied upon, and only the difficulty of its execution by the old methods upon affected surfaces in the oral, aural, and vaginal cavities detracts from its superiority over every other.

The application to surfaces in these cavities is often made by blowing the powder through a glass tube or a roll of paper, one end of which is held in the mouth of the operator. The danger, to say nothing of the inconvenience to the physician in so doing, is

often very great. About a year ago a physician in this place, while making an application of powder in this way through a roll of paper to a diphtheritic throat, contracted the disease, and in a few days his chances for life were trembling in the balance.

The powder-blower sold in the shops is so imperfect in its work and construction that it is seldom found in use. In it the bulb is compressible, but it is necessary to place the thumb over a hole in the side of the bulb as it is compressed in order to compel the air to escape by way of the tube, and thereby carry the powder with it. The bulb attached to the end of the tube and in line with it brings the hand when operating it directly in the way of vision, and so obstructs efficiency. The powder is dropped through an oval opening in the tube with considerable difficulty in charging it, and, upon compressing the bulb, it is all blown out at once, making necessary the delay and inconvenience of "loading up" again before proceeding in the application.

To overcome all such dangers and difficulties I had the following instrument made for me by Messrs. Tiemann & Co., of New York.

It consists essentially of three parts, viz., the bulb A, the reservoir B, and the barrel C. The bulb A is of soft rubber, and compressible. It is equipped with two valves, one at E and one at F, both opening in the same direction. The reservoir and barrel are of hard rubber, and are detachable at H from the bulb for packing or cleaning. The reservoir is closed by a cap, which screws closely down upon its top. To operate it the cap of the reservoir is removed, and the medicament in fine powder dropped in, of which in bulk it will hold quite a teaspoonful. The cap is then screwed on, and it is ready for use.

The advantages or superior qualities of this instrument consist, first, in the bulb A being below the line of vision, and so out of the way, thus enabling the operator to keep the

affected parts in view and make the application with greater accuracy; second, in the facility of loading the reservoir and in the quantity it will hold; and, third, in the ability to make long continuous application without the trouble of refilling the reservoir.

It has proved in my hands very efficacious, and the facility of its operation will, I think, recommend it for general use.

#### ON THE INFLUENCE OF FEVER UPON THE ARTERIAL PRESSURE.

WIEGANDT communicates to the *Centralblatt für Medicinische Wissenschaften* of January 2, 1886, his observations made on fever-patients with the view to determine the arterial pressure before and after the administration of antipyretics.

Eighteen experiments made with kairine in typhoid fever (one in erysipelas) gave wholly negative results. Eighteen further observations with antipyrin (in cases of typhoid fever, pneumonia, erysipelas, pyæmia, and tuberculosis) showed important differences only in four patients, especially in the instances of erysipelas, tuberculosis, and pyæmia. In the two former instances the blood-pressure was found to be lowered, and in the latter raised, after the reduction of the temperature by the drug. In five patients (cases of typhoid fever, pneumonia, and erysipelas) who had received thalline, the blood-pressure fell only in erysipelas after the fall of temperature, while in the two other affections no change in the pressure was observed. The influence of

defervescence upon the blood-pressure is consequently either wholly negative or only a very slight one.

Three observations made with cold baths gave, as was expected, very similar results.

#### LAUGHING-GAS.

That the so-called laughing-gas is after all not as innocuous a drug as possibly many dentists tell their patients, has recently been strikingly proven by the case of DR. DUCHESNE, of Paris, who had a patient die while under the influence of this anæsthetic. It will consequently be indicated to employ greater care in the use of laughing-gas than has been done hitherto, and to examine the patients to be anæsthetized as to a possibly existing cardiac defect.

Foreign subscriptions may be ordered through our agent in England, Mr. H. K. Lewis, Medical Publisher and Bookseller, 136 Gower street, London. Price 10s. Remittances may be made either by Postal Order or Stamps.

Price to Foreign Subscribers direct (postage included) \$5.50 (10 shillings). English postage stamps received on remittances.

Editorial communications should be addressed 1025 Chestnut Street, Philadelphia. Business communications should be addressed to the publisher.

## Leading Articles.

### ACCIDENTS FOLLOWING THE USE OF COCAINE.

THE rapidity with which reports are appearing of various forms of accident following the use of cocaine show that this drug, like nearly all other valuable articles in our materia medica, is not entirely free from its disadvantages, and they point to the necessity which must be observed in the selection of cases suitable for the use of cocaine or to the more careful study of the conditions which should govern its application. Bunge, in the *Klin. Monatss. für Augenheilkunde*, vol. xxxiii. p. 402, reports three cases of exfoliation of the corneal epithelium after the instillation of a three per cent. solution of cocaine into the eye previous to an operation for cataract, while in the fourth case vesicular keratitis lasting for five weeks followed local applications of this drug. Bunge's experience appears to have been unusually unfortunate, as he further states that in six cases of cataract operated on under cocaine-anæsthesia he noticed parenchymatous cloudiness of the cornea, which in one case was intense enough to entirely exclude light from the eye.

Unfortunately, the experience appears to be

very general as to the production of panophthalmitis after the use of cocaine either in solution or in gelatin disks, and at a recent meeting of the Clinical Society of London (*Pharm. Journ. and Trans.*, November 28, 1885) the majority of the members present seemed to believe that such a consequence was very frequently the result of the cocaine. Gräfe also states that he has found chronic interstitial keratitis much more common than before its employment.

It even appears that the instillation of cocaine into the conjunctival sac may produce symptoms of general intoxication. A number of such cases are recorded. Thus, Mayerhausen (*Centralb. für die Gesamte Therapie*, October, 1885) relates a case of a girl 12 years of age in whom 2 drops of a two per cent. solution were instilled in the conjunctiva four times, at intervals of five to eight minutes, for the removal of a portion of the cornea, injured and stained through a wound from a steel pen. In all only a little over  $\frac{1}{10}$  of a grain was administered, of which certainly one-half must have been lost through the tears. Immediately after the operation the child commenced to complain of headache, which became more and more severe until it was almost unbearable. Nausea and vomiting persisted through the entire day. The patient was greatly prostrated; stumbled in walking, her speech was almost entirely destroyed, as though her tongue was paralyzed. These symptoms of poisoning lasted all through the night, in which no rest was possible, and gradually disappeared towards the evening of the following day. In commenting on this case, Königstein calls attention to the difference between these symptoms and those which are generally recognized as characterizing cocaine-poisoning, and he suggests their similitude to the symptoms of atropine-poisoning, and doubts whether the preparation employed could have been a perfectly pure one; while, on the other hand, he suggests that the operation on the cornea through reflex action from the trigeminal nerve might be sufficient to evoke the symptoms detailed above. It hardly seems credible that a cocaine preparation could be adulterated with atropine, and it seems to us that, in the present state of our knowledge of the physiological action of cocaine, we can hardly exclude the results above given from that action simply because they do not tally with the general ideas which we have now as to that action.

Dr. Ziem also reports a somewhat similar case, in which 2 drops of a four per cent.

solution of cocaine applied to the eye of a man caused symptoms of syncope (*British Medical Journal*, November 21, 1885). In a few minutes after the pupils had become dilated, the patient's face became pale, sweat broke out on his forehead, and his breathing became embarrassed. Dr. Zeim refers to seventeen other cases recorded in ophthalmological literature in which toxic effects followed the use of cocaine. In three it was injected hypodermically, and in fourteen it was brought into the conjunctival sacs. In some of these cases the symptoms were transient, and consisted of pallor of the face, giddiness, and sweating of the face and neck. In others there were dyspnoea, great feeling of prostration, malaise, and apathy, lasting sometimes for several days. Vomiting and headache have been rarely present. The subjects were in some cases feeble, aged women; in others they were strong and healthy individuals, both male and female. Dr. Heymann, in the *Deutsche Med. Wochen.*, No. 46, 1885, reports a case in which the symptoms following the use of cocaine very closely resemble those above reported by Mayerhausen. The patient was a boy, in whom solution of cocaine was liberally applied to the pharynx and larynx for the removal of a small papillomatous growth from the latter. Even before the tumor was removed the boy began to show signs of intoxication; he was apathetic, spoke in a halting, hesitating manner, and had considerable difficulty in walking. Pulse, temperature, and respiration appeared to have been all slightly increased. The symptoms gradually passed off ten hours after the operation. Dr. de Haviland Hall (*Lancet*, November 21, 1885) describes a case in which cocaine spray applied to the posterior nares caused laryngeal spasm.

It is, of course, as yet impossible to say whether these effects are due to idiosyncrasy, or whether they are caused by decomposition in the solution of cocaine. This solution, as is well known, is not a permanent one, and is particularly liable to the development of fungous growths, and we have already at various times referred to different methods of preserving cocaine solutions. Of course the best method is to make the solutions fresh when required. Mr. H. McHardy, who has often met with disadvantageous results from the use of cocaine, thinks that fifteen days is the longest time that it is advisable to keep the solution of cocaine. Gelatin disks containing cocaine are hygroscopic, and they also are not any more per-

manent or but little more permanent than the watery solution of the alkaloid.

In this connection a case of cocaine-poisoning very closely resembling opium-poisoning, and reported by Dr. J. S. Spear in the *Medical Record*, November 14, 1885, is of interest. The case was that of a man aged 29 years, who, after being on a spree, took a hypodermic injection of the cocaine solution, as he expressed it, to sober up with. About two hours afterwards it was noticed that his face was ashy pale, hands and lips quite blue, drops of perspiration covered his forehead and ran down his neck. His eyelids were tightly closed, mouth half open, pupils contracted, pulse feeble and fluttering and not countable, face congested and of a whitish-gray color, and the body bathed in a cold perspiration. Respiration slow and almost imperceptible, and not at all stertorous. A diagnosis of opium-poisoning was made and the stomach-pump employed, but the stomach was found empty, and  $\frac{1}{10}$  of a grain of atropine was then injected, and strong coffee forced down the throat, the patient at the time being unable to swallow. Under flagellation, and possibly as the result of the above treatment, in about one hour and a half he showed signs of returning consciousness. After taking coffee several times he finally vomited it, and gradually recovered. He then gave the following history as to the details of the case:

His occupation is a hospital nurse in the U. S. Marine Corps, and he is addicted to the use of cocaine to allay a craving for alcoholic stimulants. On the afternoon of October 15 he left the barracks about two o'clock, went directly to the manufacturing laboratory of Dr. Edward R. Squibb, in Brooklyn, purchased two small vials, each containing five grains of muriate of cocaine in powder, dissolved the same by filling the vials with water which he obtained in a bar-room; he then crossed over to New York, had his hypodermic syringe repaired at an instrument-maker's shop, and about 3.30 P.M. gave himself the first hypodermic of cocaine, probably about 1 grain.

He had already taken several drinks, and continued to drink from time to time all night, going from one saloon to another. Every few hours he took a hypodermic of cocaine. He thinks he was not intoxicated at any time, is quite sure he did not spill any of his cocaine, but took it all before he returned to the barracks at 8.30 A.M., except the last portion, which he took in the cell as before related.

He declared most positively that he did not purchase nor take any morphine on this occasion, and indeed never took a dose of morphine in his life, and offered to make an affidavit to that effect. There was no evidence of suicidal intent. The purchase of the cocaine was confirmed by inquiry made at Dr. Squibb's laboratory, where it was stated that the same man had frequently purchased cocaine there before. The two vials with Squibb's cocaine labels on them, both empty, one corked, were found in the cell. Both showed unmistakable signs of having recently contained cocaine and not morphine. His own hypodermic syringe had been used to administer the atropine, so that an examination of its contents for cocaine or morphine was considered unreliable.

#### ON THE ACTION AND ELIMINATION OF IODIDES.

THE high repute which iodine and its preparations have enjoyed ever since the introduction of this metal into therapeutics by Curtois at the beginning of this century, rests almost exclusively upon an empirical basis. The physiological and experimental researches instituted with these drugs have hitherto shed but a dim and scanty light on the actual mode and nature of their efficacy. It is almost easier and shorter at the present day to enumerate the maladies in which iodine and its preparations are not ordered than those in which they are employed. This state of affairs is aptly illustrated by the well-known *bon-mot* appearing in the text-book of Nothnagel-Rossbach: "When the physician is at a loss what to do, he prescribes the iodide of potassium." Only a year or so ago the medical world received with surprise the authentic report of an entirely new pathological field for the curative power of iodide of potassium (*Progrès Médical*, October 4, 1884), Prof. Fournier, of Lille, publishing a case of genuine tubercular lupus which was cured solely by this drug.

Still, in spite of the uncertainty and even confusion which exists in our knowledge of the therapeutic virtues of the iodides, clinical experience has well established their high value in a number of morbid processes, among which deserve to be especially mentioned syphilis, hypertrophy of the thyroid body, scrofulosis, gout, alterations of the aorta and great vessels, asthma, chronic bronchitis, and albuminuria.

If, however, experience has taught us numerous indications for the employment of iodides, it has given us no insight into their *modus operandi*; we are, in one word, very rich in empirical facts, but very poor in rational notions as to these important remedies.

Regarded by some therapeutists as moderating agents of nutrition, by others as stimulants of the same, the iodides have in turn been accused of producing obesity and reducing it, of augmenting diuresis and diminishing it, of increasing the elimination of urea and decreasing it again. This conflict of contradictory opinions compels us to appreciate the thorough and strictly scientific study of Dr. Eugène-Louis Duchesne (Paris, Inaugural Essay, 1885) on the action and elimination of iodides, which we hereby present in its essential features to the readers of the *THE THERAPEUTIC GAZETTE*.

#### I. ACTION OF IODIDES ON DIURESIS.

*Iodide of Potassium* was administered in fifteen cases in doses varying from  $7\frac{1}{2}$  to 75 grs., and for a period of two to thirteen days, and gave the following results: In seven cases the urine was noticed to be increased slightly (2 to 8 oz.), and in one case greatly (30 to 34 oz.). In seven cases a slight diminution of the urine was observed during the period of the administration of the drug (2 to 7 oz.).

These variations move between such restrained limits and show such direct oppositions, that we are forced to assume that they are wholly independent of the influence of the drug.

*Iodide of Sodium*.—This drug was administered in one case in doses of 60 grs. *pro die* for a period of nine days, with the following results:

The urine increased 2 oz. during the period of administration; in another case, where 30 grs. were given for six days, a diminution of 22 oz. was observed. During six days following upon the cessation of the drug, the diminution of urine amounted to one quart. It is hard to draw any definite conclusions from these contradictory observations.

*Iodide of Calcium*.—In two cases where this drug was administered in daily doses of 30 and 60 grs. respectively for a period of six days, a diminution of 5 to 6 oz. during the period of administration and during the following period was noted. We know, then, that the iodide of calcium does not increase urination, but rather appears to diminish it.

*Iodide of Ammonium*.—This drug administered in doses of 45 grs. daily for six days pro-

duced an augmentation of 4 oz. of the urine for the first three days of administration. During the fifteen days following upon the cessation of the drug, this diminution amounted to 14 oz. In another case, where 15 grs. was given for nine days, an increase of 24 oz. during the first four days, and a diminution of  $5\frac{1}{2}$  oz. during the five last days, was noticed. During the five days following upon the cessation of the drug the diminution amounted to 8 oz.

These two results go to show that iodide of ammonium augments slightly diuresis during the first few days of its administration, and decreases it later.

*Polyiodides* (KI, NaI, CaI,  $\text{NH}_4\text{I}$ ).—In one case where the polyiodides were given for five days in equal and progressive doses of 15 to 75 grs., the urine decreased 20 oz. during the period of administration, and increased 4 oz. during the following five days. In a second similar case a diminution of  $3\frac{1}{2}$  oz. during the period of administration, and an increase of 39 oz. during eight following days, took place.

The combination of iodides appears thus to act inversely as the iodides alone,—viz., to diminish diuresis at the end of the administration of the drug, and to increase it during the days following upon the cessation of the drug.

*Tincture of Iodine*.—In five cases where the tincture of iodine was exhibited in progressive doses of 8 to 28 gtt. for a period of five to fourteen days, the urine increased in every case (excepting one)  $4\frac{1}{2}$  to 26 oz. during the period of administration. In the six days following in all cases (excepting two) a diminution of 10 to 28 oz. was observed. Hence we learn that the tincture of iodine increases urination at first, and then after cessation of the drug leads to a diminution of the urinary quantity.

## II. ACTION OF IODIDES ON UREA.

*Iodide of Potassium*.—Under the influence of this drug urea was found to increase. This increase persisted, and even grew during ten or fifteen days following upon the cessation of the drug. These variations, though, are not great, from 30 to 45 grs. usually; they never exceed 120 grs.: in one case only the enormous figure of 210 grs. was reached. The dose, the mode of administration, and its duration, did not influence in any way these variations.

*Iodide of Sodium*.—This drug given in a comparatively large dose (60 grs.) produced a temporary increase of urea, which was soon

followed by a notable decrease, lasting for several weeks after the cessation of the drug, and amounting to the enormous figure of fifty per cent.

*Iodide of Calcium* lowered quite appreciably the figure of the uric excretion even for a period of two weeks after cessation of the drug.

*Iodide of Ammonium* raised the secretion of urea at the end of the administration of the drug, and lowered it during the following eight or ten days.

Polyiodides were found to decrease the excretion of urea during their administration, and to raise it during the period following upon the cessation of the drug.

*Tincture of Iodine*.—Out of five cases in which the tincture was given, our author records an augmentation of urea in four cases during the period of administration and during the following three days. His conclusion as to the effect of the tincture of iodine was that the latter had a varying effect upon nutrition as to the exhibited dose; in a dose of 16 gtt. and exhibited for a period of about a week, the tincture was found to exert a decidedly favorable effect upon the general nutrition. If, however, this dose be exceeded and the period of administration prolonged, the reverse condition—viz., a notable depression of nutrition—took place.

*Action of Iodides on Uric Acid*.—The iodides of potassium and calcium were found to slightly increase the excretion of uric acid.

The iodide of ammonium produced a considerable augmentation of the uric acid excretion, while the polyiodides lowered the same.

At the conclusion of his study Dr. Duchesne arrives at numerous interesting results as to the action of the iodides on nutrition and their mode of elimination, which we shall briefly refer to.

The iodides have but a slight action on diuresis.

Their influence is marked by a slight increase of the urinary excretion during the period of administration of the drug, and at times during the first few days of this period only. This increase is soon followed by a decrease, which persists for ten to fourteen days after discontinuance of the drug. Among the salts of iodine, the iodide of potassium showed the feeblest action in this respect.

The iodide of ammonium and the tincture of iodine act alike on the urinary excretion, increasing it during the period of administration, and reducing it immediately after cessation of the drugs.

The elimination of nitrogenous matters (urea and uric acid) is modified by both the salts and the tincture of iodine, though the various preparations do not act alike. Iodide of potassium augments the ureic excretion during the period of administration, and during the following ten to fourteen days. This augmentation, which is always 30 to 45 grs. daily, may amount to 105 to 120 grs. (exceptionally to 225 grs.). The tincture of iodine acts as the iodide of potassium, but more energetically.

All the preparations of iodine favor likewise the elimination of uric acid during and after the period of administration. Their association, however, and the tincture produce the opposite result. During and after their administration the uric acid elimination is decreased.

These observations show the impossibility of considering the iodides *en masse* either as stimulants or depressants of nutrition, as some favor the elimination of nitrogenous matters, as the tincture of iodine and the iodide of potassium, and others retard this elimination, as the iodides of sodium and calcium.

Therapeutically, we infer from these facts that, wherever an energetic action upon nutrition is intended by intensifying the process of nitrogenous elimination, the potash combinations, or still better the metallic salt, recommend themselves. Such indications would arise in all maladies attended by a weakened nutrition, such as stone in the bladder, gout, rheumatism, and others.

#### BISMUTH PREPARATIONS.

THE great difficulty which in the past has attended the therapeutic use of the salts of bismuth in large quantities has been their proneness to contain arsenic. We well remember having produced severe arsenical poisoning by the administration of a preparation of bismuth which had been made by one of the largest and most reliable chemical establishments in the United States. This liability to arsenical contamination grew out of the fact that the only bismuth ores formerly in use were those of central Europe, all of which contain arsenic in abundance. Since the discovery of ores of bismuth in South America, which are free from arsenic, the practitioner need not fear to use this drug in very large doses.

There are one or two therapeutic points in regard to the salts of bismuth which it has

seemed worth while to call attention to. In the first place we hardly think that the bismuth preparations are employed as frequently as local remedies in inflammations of the mucous membranes as they deserve to be. They seem to us to be distinctly sedative, and at the same time slightly astringent, and may be used freely in the most acute stages of mucous inflammation. Thus, in the beginning of an acute nasal catarrh bismuth may be blown by means of a quill freely into the nostrils, often with great relief. If 5 grains of the carbonate of sodium be added to 2 drachms of the bismuth it will often be found serviceable. In gonorrhœa, during the most acute stage, injections containing 20 to 40 grains of bismuth suspended by means of some mucilage and repeated every two or three hours, sometimes act most advantageously.

As is universally recognized, these salts of bismuth are of great value in all gastric or intestinal irritations. When the stomach itself is affected, the bismuth should be given just before or immediately after the meal; the doses are not less than ten grains, the object being, of course, to have the bismuth retained in the stomach and brought in contact with the mucous membrane of the stomach as thoroughly as possible. In many cases it would be better to give the bismuth a half-hour before the meal. When it is desired to influence the mucous membrane of the intestines the bismuth must be given in much larger doses, 20 grains to a drachm; but especially is it desirable that it be administered about two hours after eating, when the contents of the stomach are rapidly passing into the intestines, in order that the bismuth may be hurried through the stomach as rapidly as possible and reach the intestines in an unaltered condition.

The remarks which we have been making refer to the insoluble preparations of bismuth,—the subnitrate and the subcarbonate,—which do not in any way differ from one another in their relations to the human organism. The soluble ammonio-citrate of bismuth is a very astringent and decidedly irritant remedy which, in our practice, has failed to prove itself possessed of any special value.

#### AN ABUSE OF VIVISECTION, BUT NOT BY PHYSIOLOGISTS.

AS our readers well know, we have taken occasion from time to time to protest against the false statements and the ranting rhetoric of antivivisection literature. It is to our mind

a great pity that so much of energy and so much of humanity should by its misdirection do evil rather than good. We sympathize most heartily with all properly directed efforts to reduce the amount of animal suffering in the world, and we would therefore suggest that our readers should call the attention of the various societies for the prevention of cruelty to animals and of humane individuals to the practical vivisections which are performed in private and public slaughter-houses in all portions of these United States with thoughtless or reckless brutality.

The slaughtering of animals is of course necessary; but death should be inflicted with as little pain to the animal as possible. When the throat of a sheep or a calf is cut, some minutes of psychical and physical suffering must ensue; since, even if both carotids be thoroughly divided, the vertebral arteries will suffice to supply enough blood to maintain more or less complete consciousness. Pithing of the sheep or of a calf would be a very simple operation, and would in no wise interfere with the free bleeding if the throat was cut immediately.

In the case of cattle, pithing is usually impracticable; and shooting, which is practised, we believe, in Chicago, is liable to cause serious accident. A properly-directed blow, given with sufficient force upon the front of the head below the horns, will cause an instantaneous loss of consciousness, and affords, unless under exceptional circumstances, the best means of killing. The difficulty is that the blows are frequently so bunglingly given that they have to be repeated time and again.

A recent inspection of the large building which, under the control of the Pennsylvania Railroad, constitutes the chief abattoir of Philadelphia, led to the witnessing of the sickening procedures there indulged in. Driven into open pens in crowds, maddened or cowed, according to the individual disposition, by the sight of their stricken comrades and the surroundings of death and blood, the unfortunate brutes, one by one, received the fatal hammer. Occasionally a deftly-delivered blow would cause the animal to fall paralyzed in all its nerve-functions; more often two, three, four, five, or even six times would the stroke have to be given, the animal falling to his knees, struggling up, trying to crowd his way among his fellows, only at last to perish. Then again, even when the steer had fallen unconscious, often was so long a time allowed to elapse before cutting the throat that the beast would regain sufficient power

to feel, and sometimes even to get upon his feet.

A little of the eloquence displayed at a late meeting of the Antivivisection Society by the learned counsel of the Pennsylvania Railroad, whose knowledge of law, we trust, is as great as his ignorance of physiology and its needs, might be usefully employed in the furtherance of abattoir reform.

#### THE GALVANO-CAUTERY AS AN EFFECTUAL TREATMENT OF DIPHTHERIA.

THAT all therapeutic interferences at present employed in diphtheria play little more than a palliative rôle, without in any way modifying the diphtheric process itself, is unfortunately an indisputable fact with all clinicians and practitioners. To look for new remedies of the vegetable or mineral kingdom, or the products of the chemical laboratory, which might possibly exert a specific, or at least a salutary, influence over the affection, must at last appear a fruitless endeavor. Drugs do not and cannot cure diphtheria, and other measures must be thought of, unless we wish to abandon our patients wholly to the mercy of this dreaded foe. Almost simultaneously, and certainly independently of each other, the report of the successful exhibition of a new remedial procedure, viz., the galvano-cautery, comes to us from two different quarters. Dr. Bloebaum presented his experience with the galvano-cautery in diphtheria in a recent number of the *Deutsche Medicinal Zeitung* (p. 973, 1885), and expresses his unqualified satisfaction with the results obtained, while in the *Rivista Venet.* of November, 1885, we find a similar eulogy of this treatment by Dr. Tedeschi (*Comunicazione Preventiva del Dott. v. Tedeschi di Trieste*).

These authors declare that the application of the galvano-cautery does not produce the slightest pain, as the diphtheritic membrane is of course void of sensibility. At the mere touch of the glowing wire the membrane rolls up and falls off. Tedeschi emphasizes the fact that the once cauterized portion never again assumes a diphtheritic nature, and the application forms at the same time a positive check to the extension of the process over the neighboring parts. After the application of the cautery the fever is found to be sinking, and frequently to wholly disappear after two to four hours. At the same time the glandular swelling on the neck and the œdema of this region are decreasing.

The scab resulting from the cauterization falls off in eight to fourteen days, and nearly always with ample suppuration. In the first couple of hours after the application ice is found to be a useful means to limit the inflammation; later, injections of aqueous vapor are indicated to favor a rapid dissolution of the scab. Irrigations with lime-water proved a useful adjuvant to this treatment.

Unfortunately, our author has not stated how many cases have been treated by this application of the cautery. But in the face of our present therapeutic impotency in diphtheria, the method deserves earnest but cautious trial. In conclusion, we recall that the galvano-cautery is not an entirely new application in the treatment of diphtheria, but has as early as in 1857 been recommended by French military surgeons in a communication to the *Union Médicale*.

#### THE SYPHILIS-BACILLI.

THE present status of our knowledge concerning the etiological aspects of syphilis is less satisfactory than at any time before. The consciousness that a certain scientific topic is as yet unknown to us is by no means a deplorable one, for certain things in science do not appear destined to ever become elucidated to the human mind, and, besides, what is unknown to-day may be known to-morrow. It is a far more unfortunate state of affairs if some hitherto obscure subject is suddenly explained by an ingenious theory or a brilliant discovery, which is again soon objected to and refuted from numerous quarters. In the former instance we know at least that we don't know anything, while in the latter we are deprived even of this hold. These views apply precisely to our present state of knowledge regarding the etiological factors of numerous specific diseases, especially tuberculosis, cholera, and syphilis. The vacuum existing in our knowledge of the causative agents of these affections had scarcely been filled by the discovery and demonstration of specific microbes, when their specific nature was disclaimed, rejected, and disproven. True, these objections are again refuted by the original discoverers, but the practising physician, who cannot spare the time for complicated staining and microscopic work, is left wholly in doubt and ignorance.

Lustgarten's discovery of specific syphilis-bacilli and their demonstration at the medical congress in Wiesbaden meet the same fate as

has been witnessed in the instance of Koch's tuberculosis and cholera-bacilli: its specific character is questioned by authoritative observers.

We have before us two recent papers (*Centralbl. für Med. Wiss.*, January 2, 1886) by Cornil and Dutrelepont, both noted pathologists, who discuss the subject of Lustgarten's bacilli in an able and impartial manner.

Cornil refers to the works of Alivarez and Pavel, who found in the preputial smegma, in the vulva and anal orifice, a bacillus which closely corresponds to the microbe discovered by Lustgarten. These observers failed to detect the bacillus in eight syphilitic excrescences, in spite of many sections and strict observations of Lustgarten's instructions, while out of fifty-five cases of syphilitic secretions it was found thirty-three times. Cornil advances the following theses:

(1) In several normal secretions of the body a bacillus exists which has heretofore been unknown.

(2) This bacillus is, regarding its form and functional properties, identical with the microbe described by Lustgarten.

(3) It is possible that both bacilli are actually one and the same.

(4) The bacillus occurring in the ordinary secretions resembles in form the bacillus tuberculosis, and shows a certain behavior as to coloration which is only found in the bacillus of tuberculosis and leprosy.

(5) From the bacillus tuberculosis this microbe differs, besides in its smaller size and its less granular appearance, by its lesser resistance against alcohol after the coloration with fuchsin and the treatment with nitric acid, nor can it be stained by Ehrlich's method with methylviolet.

(6) These facts deserve to be considered if we intend to establish a diagnosis on the microscopic inspection of secretions.

Cornil concludes his paper by remarking that the works of Alivarez and Pavel are still incomplete, as no cultures of their microbe have as yet been made; hence their pathogenetic nature is of course an open question. But this is equally questionable in the case of Lustgarten's bacilli, as no cultures of it have yet been made.

Dutrelepont communicates his continued investigations of the syphilis-bacilli. He found them in nine cases of sclerosis, in one of a broad condyloma of the external labiæ and anus, viz., in five papules, one gumma, and in the secretions of mucous patches and indurated ulcers of the upper lip.

All attempts of making a culture have proved futile.

These observations show that it is as yet impossible to either wholly accept or wholly reject the specific nature of the microbes detected and described by Lustgarten, and that further investigations have to be made in this direction.

#### LEAD-POISONING.

IN a recent editorial we called attention to the fact that the absence of a blue line upon the gums is no proof that the patient is not suffering from lead-poisoning. A case which has recently occurred in the practice of Dr. Wood, in Philadelphia, seems to us of such great interest, as showing the necessity of the practitioner always being on his guard in regard to this form of poisoning, that we notice it editorially. A gentleman in the centre of Pennsylvania was taken ill with very obscure nervous symptoms which developed after domestic and business troubles, and which appear to have been attributed by his various medical advisers to overwork and overworry.

To show the possible obscurity of lead-poisoning and the difficulty of recognizing it, it is allowable to state that this victim was first under the care of his local practitioner; afterwards for a period under that of one of the most eminent Philadelphia professors; then, under the advice of an eminent neurologist of New York, went abroad in charge of a young physician. Subsequently he came to Philadelphia, and was for some weeks under the care of a physician of world-wide renown. During all these months the nature of the case was not suspected.

The chief symptom in the man's case was, as it had been all along, a peculiar insomnia of the most aggravated type, so that the patient for many months had not consciously slept two consecutive hours except under the influence of very large doses of narcotics. So soon as he would get into bed he would be seized with a feeling of unrest associated with a peculiar irritation of the skin, with formications and itchings, which affected not only the skin, but also the mucous membranes, taking at times the form of burning pains along the urethra. There was also a feeling as though the man must walk, so that he would be forced in a few minutes out of bed, and would pass the whole night pacing up and down the floor. Night after night the patient had been driven backwards and forwards until he had fallen, on more than one occa-

sion, upon the floor from sheer exhaustion. In several places he had been asked to leave boarding-houses and even large hotels on account of the disturbance produced by his nocturnal habits. There was no palsy, no failure of mental power, no other symptoms present than those which we have described. In examining the case Dr. Wood first came to the conclusion that the insomnia was probably secondary, and produced by the peripheral nervous disturbance. It is a fact that persistent universal peripheral irritations giving rise to pruritic sensations, when not connected with the change of life in women, are, in the great majority of cases, due to the presence of some toxic agent. Such a poison in a large proportion of the cases is gouty, but there was in the present case no gouty history, and no gouty symptoms other than the peripheral irritation. This led to the suspicion that possibly the poisoning was plumbic; but on examining the mouth no blue line was discovered upon the gums. In going over the history, however, the patient stated that at one time he suffered from horrible abdominal pains, which he affirmed usually came on shortly after eating, and were often unbearable. This condition lasted for some weeks, during which time the patient was excessively costive, the stools being scybalous and light of color. The next inquiry was as to the water-supply of the patient's home, and it was found that the gentleman occupied a country mansion supplied with, as he stated, "beautifully pure water from a mountain spring running through metal pipes."

With this positive history and the negative facts that no known nervous disease conforms in its type with the symptoms present in the case, Dr. Wood believed that the diagnosis of lead-poisoning was justified. Chemical examination of the water used in the house of the patient showed that it contained a large proportion of lead; further, although the patient had been away from home about a month, and had not been using the water containing lead, Dr. Marshall, of the University Chemical Laboratory, found lead in the urine. The process employed by Dr. Marshall was to boil three litres of urine down to about two ounces, adding nitric acid until the organic matters were thoroughly charred, then suspending in the liquid two pieces of platinum foil respectively connected with the positive and negative poles of the battery. After the current had been passed for an hour or two a distinct discoloration of the platinum connected with the negative pole of the battery was ob-

served. This platinum was then heated in diluted nitric acid, and through the solution thus obtained sulphuretted hydrogen was passed. The black precipitate which formed was collected, and when reduced by the flame of a blow-pipe on a piece of carbon, yielded metallic lead.

#### A NEW DISINFECTANT.

ANY novel facts in regard to disinfectants are of such importance that we give prominence by putting into our editorial columns the results of some researches made by Dr. A. C. Abbott in the Biological Laboratory of the Johns Hopkins University (*Medical News*, January 9, 1886). If, as it is claimed, the stannous chloride is free from poisonous properties, it ought to be used very largely as a disinfectant. Dr. Abbott finds that the stannous chloride comes far short in the germicide value of mercurio-chloride; but when in contact with spores in decomposing organic matter, kills them at one per cent. after an exposure of two hours, and that it failed to disinfect the mass when present in 0.8 per cent. after the same length of time. Comparing these figures with those indicating the potency of zinc chloride, copper sulphate, zinc sulphate, and ferric sulphate, which are the salts most generally used for the purpose of disinfection, we find the first of these, zinc chloride, to be active in five per cent., and inactive when present in 2.5 per cent.; while the last three—copper sulphate, zinc sulphate, and ferric sulphate—we find to be inefficient respectively in twenty per cent., forty per cent., and in saturation. These facts, taken in conjunction with the moderate cost of stannous chloride, and its entire inactivity on lead pipes, are sufficient to indicate a large field of utility for this compound.

IN our last issue, the author's name of "Notes on Brucine" should have been Dr. Ralph W. Seiss, instead of Ralph W. Zeiss.

#### Reports on Therapeutic Progress.

##### ON PNEUMO-BULBARY ASTHMA.

The affection known under the name of asthma has seen many a strange change before it could maintain a firm position in the therapeutic science. In the early days of medical knowledge "asthma" meant all forms of dyspnoea. Galen and Celsus, for example,

regarded asthma, dyspnoea, and orthopnoea all as one single pathological group.

Sydenham recognized three various forms, Willis and Cullen added each three new categories, and Sauvages finally described eighteen. This modification of different varieties of asthma would have been infinitely continued unless the light of pathological anatomy had demonstrated their true character as mere phenomena dependent upon various morbid alterations of the heart, the aorta, and the lungs.

Later a serious and remarkable reaction took place, which reached its culmination by Rostan's proscription of this affection in 1821, who simply eradicated its name from the clinical nomenclature in favor of affections of the aorta.

Laennec, again, created a third and new phase for this affection. Noticing that some of his patients were seized with nocturnal paroxysms of dyspnoea, he constructed for these cases the term of "essential asthma." This is the "petit asthme du soir," which has still a singular hold upon the professional mind. If found to deviate, however, from the ordinary type, it is no longer recognized, and its doom is complete if it is found to be associated—as is, in fact, always the case—with emphysematous and catarrhal conditions. Hence in our hospital-lists we read only of emphysema and catarrh. Louis established the autonomy of the emphysematous process, while Bean in his remarkable paper on asthma referred all pertinent symptoms to the bronchial catarrh. For a large number of cases this view was correct, especially in opposition to the so-called "nervists," who regarded the whistling respiration solely as the characteristic, and the bronchial cramp as the cause, of asthma.

PROF. G. SÉE, in the third volume of his still unpublished *Médecine Clinique*, proposes to establish the affection upon its true clinical basis, and to present the clinical proofs that no asthma exists without dilatation of the air-vesicles and a fibrinous exudation, that frequently a genuine catarrh coexists, and that the "petit asthme essentiel nocturne" in the course of time appears also during the day. In this connection he endeavors to show how the lungs are invariably expanded to the utmost, until they form an inelastic sac, which is designated as emphysematous, and that finally the asthmatic catarrh becomes unimpeachable.

Dr. Sée believes that asthma forms a triology, having a nervous, a mechanical (alveolar), and secretory (bronchial) basis.

*Definition—Nervous Origin.*—Every dyspnoea dependent upon an alteration of any organ is not a true asthma; no matter whether this dyspnoea is accompanied by emphysema or not, it is nothing more than a symptom; a pseudo-asthma. The cardiac asthma is the type for this category.

Asthma can only be regarded as genuine and as an independent affection when its nervous origin is established. Asthma, then, is a neurosis of extreme importance, chronic, and invariably marked by paroxysms presenting a definite mechanism, a precise character, and a fixed localization. The actual seat of this neurosis is the medulla oblongata and the respiratory centre in it; its cause, an inherited or acquired or heightened reflex irritability of this organ. As exciting causes of the paroxysms we must assume irritations radiating from the pneumogastric or the peripheral nerves, such as the trifacial, while as effect we have the activity in the motor nerves of the inspiratory muscles, chiefly the diaphragm. We therefore have to deal in asthma with a permanent neurosis of the medullary bulb, proceeding from an irritation chiefly in the vagus, and resulting in a tetanoid contraction of the diaphragm.

*Experimental Argument.*—In its character of neurosis asthma is a domain of experimental medicine; the experiment, however, can only be viewed as conclusive if all phenomena, and all functional interference observed in patients, are reproduced by it. If physiology shows us an artificial dyspnoea with expanded pulmonary alveoli and a bronchial catarrh, we have the true experimental asthma; if, however, one of these sequelæ be wanting, we would have only a fragment of human pathology and an imperfect asthma. This has been done recently; first the convulsive dyspnoea has been produced, then a dyspnoea with pulmonary ectasy (ectasis pulmonum), but the artificial production of the catarrh has not yet been accomplished.

I. *Artificial Broncho-Spasmodic Dyspnoea.*—When Laennec first recognized that form of nervous asthma, which can be termed a limited one, as he excluded every material lesion of the lung, especially catarrh and emphysema, the convulsive contraction of the bronchial muscles (discovered by Reisseisen) was universally looked upon as the causative agency of the dyspnoea. This theory, aided by experimental physiology, held long supreme sway, and is still held by many authors.

II. *Bulbo-Phrenic Dyspnoea.*—Meanwhile, Wintrich advanced his objections against

this theory, and urged especially that the bronchial spasm could not produce nor explain the enormous alveolar distention, the expansion of the lungs far beyond their normal limits,—in one word, the emphysematous dilatation which invariably attends the asthmatic paroxysm. As long as nineteen years ago Dr. Sée endeavored to show that not the bronchial muscles, but the sensory fibres of the vagus, formed the origin of the paroxysm, and that transferred to the medulla oblongata and the motor inspiratory muscles, the phrenic nerves were ultimately reached. And as the result of this reflex phenomenon we have the tetanoid contraction of the diaphragm, the prolongation of the chest, and the dilatation of the lungs.

All clinicians excepting Bamberger, in Vienna, upheld this view faithfully, though it was fiercely attacked by many. Riegel, one of its strongest supporters, has recently, in an experimental essay, declared his error and demonstrated the neurotic nature of asthma.

III. *Artificial Catarrh.*—These two main points, then, the dyspnoea and alveolar dilatation, have been furnished by the experimental science, and there only remains to show how the bronchial secretion originates.

*Résumé.*—The nature of asthma, then, is established on a neurotic basis, and the affection is a pneumo-bulbary, or, better, a pneumo-bulbo-phrenic one. There will be different types only remaining: if the nervous element predominates we will have the nervous asthma in the special sense; if the emphysema is pronounced, the alveolar or emphysematous asthma; and, lastly, if the bronchial catarrh is conspicuous, we will have the bronchial asthma.

*Difference between the Neurotic and Pseudo-asthma.*—A large number of morbid conditions may give rise to paroxysms which simulate the genuine asthmatic attack in all respects but differ wholly in their origin. The principal pseudoasthmatic paroxysms are cardiac, uræmic, tuberculo-pulmonary, laryngeal, and cerebro-spinal. In all these cases a thorough examination will reveal the existence of a primary organic lesion, hence a condition which can be distinctly separated from a neurosis.

*Quantity and Appearance of the Expectoration.*—A certain number of cases show no sputum whatever. Usually the expectoration is scanty, consists of small, hard fragments of a pale gray and semitransparent color. We find in them two main elements, viz., peculiar crystals and spiral threads.

I. *The so-called Asthma-Crystals.*—In these fragments, and in the middle of the spirals or the pus-cells, we find octahedral crystals, which have been long ago demonstrated by Charcot in the leucæmic spleen and in the medulla of bones. These crystals, apparently composed of phosphates and an organic basis, play, according to Leyden, a very important rôle: they are said to irritate the bronchial mucous membrane, and to thus produce the asthmatic paroxysm by reflex action. After the attack they disappear until their regeneration gives rise to another one. Levy\* has confirmed the regular appearance of these crystals in twenty-six cases observed by him.

*Objections.*—The above-mentioned observer, however, found these crystals also in the sputum of patients who, at the time, were not under the influence of a paroxysm. The crystals may also appear in fibrinous bronchitis, in acute bronchitis, in pulmonary phthisis, and in bronchial catarrh, without a trace of asthma. Consequently it is not certain whether these crystals actually produce the attack of asthma, which, according to Levy, is an epithelial catarrh. According to Ungar,† these crystals are not all pathogenetic, but are generated in the sputum outside of the body.

II. *Spiral Bronchial Secretion.*—According to Unger and Curschmann,‡ the gray or yellowish spiral threads to be found in the sputum are the actual exciting causes of the paroxysm. They are usually empty, contain air, and are in their longitudinal axis traversed by a shining central thread, which consists of finer spirals and round cylindrical cells. Their origin cannot be doubtful; they are an inflammatory exudation of the ultimate bronchioles. This shows that we have to deal with an exudative bronchiolitis. According to Curschmann, bronchiolitis is a chronic affection, observable in every phase of life, frequently combined with a chronic catarrh of the large bronchi, and producing a more or less intense expiratory dyspnoea, with pneumatosis of the lungs. This is the cause of the secondary nervous asthma. The primary nervous asthma is of rare occurrence.

*Objection.*—Vierordt|| found these identical crystals in the sputum of a patient on the seventh day of a fibrinous pneumonia; on the eighteenth day they had disappeared. V. Jaksch, Vincenzo, and Pel¶ found them like-

wise in fibrinous pneumonia, and Curschmann observed them in twenty-seven cases of pneumonia four times and twelve times simultaneously with fibrinous coagula, and not knowing what to do with these crystals, declared all those pneumonic patients as asthma-candidates!

*Résumé.*—These discussions and observations show that the bronchial secretion of asthma differs from the ordinary catarrh by the tenacity, scantiness, spiral fibres, and the frequent coincident appearance of the Charcot-Leyden crystals in the sputum. But these elements do not own any pathogenetic character, as they are also to be met with in other broncho-pneumonic affections without a trace of asthma. Hence the theory that any elements found in the sputum of asthmatic patients are the cause of the paroxysm is no longer tenable.

(To be concluded in the next number.)

#### HYOSCINE HYDROBROMATE.

DR. HENRY M. WETHERILL has been employing hyoscine hydrobromate as an hypnotic for the past six months in the Pennsylvania Hospital for the Insane, and he publishes the results of his experience in the *Med. Times*, December 26, 1885. He used a formula containing 1 grain of the hydrobromate of hyoscine, 9 fluidrachms of distilled water, and a drachm of alcohol, every 10 minims of this solution containing  $\frac{1}{10}$  of a grain of hyoscine. As a hypnotic, the usual range of dose is from  $\frac{1}{120}$  to  $\frac{1}{60}$  of a grain given at bedtime, preferably by the mouth; very frequently a less dose than gr.  $\frac{1}{120}$  will be sufficient; gr.  $\frac{1}{100}$  has often acted better in insomnia than has a larger quantity. It is very seldom necessary to repeat the dose; and another very decided advantage possessed by hyoscine over hyoscyamine is that small doses can be continued for a long time without increase; whereas the patient soon tolerates small and then moderate quantities of hyoscyamine, and finally resists even very large doses of it. Dr. Wetherill has given hyoscine a thorough trial in the insomnia occurring in the course of acute delirious mania, and with marked success, having succeeded, when all the usual modes of treatment had proved inadequate, in securing for the patient from six to ten hours of quiet sleep nightly for the past nine weeks, with but four or five exceptions, giving but one dose in every twenty-four hours, at bedtime, the amount ranging from gr.  $\frac{1}{120}$  to

1. The insomnia in these cases is one of their chief elements of danger. If it is possible to give such a case a fair amount of sleep and of nourishment in a concentrated form, the probability of a favorable issue might be entertained. In the insomnia of agitated melancholia, of the morphine habit, of alcoholism, of acute mania, of neurasthenia, of chronic mental disorder, with habitual wakefulness and motor activity, and in those confirmed cases of insomnia from unascertained cause which usually prove so obnoxious to treatment, hyoscine has been found to answer a very good purpose. It does not invariably succeed; but the failures have been very exceptional. In many instances the chronic insomniac habit has been broken so as to permit of the withdrawal of the hypnotic. It is a severe test of the value of any hypnotic to administer it in daytime, and the drug under consideration has been found to act very well even under this condition. It seems scarcely necessary to refer to the unsatisfactory and often disappointing action of the hypnotics which are now in general use, and it would seem as though this remedy is the one for which rational therapists have waited for so long a time.

Now, as to its usefulness as a general sedative, Dr. Wetherill claims that he has had results which justify the assertion that it is the very best means at present at our disposal for calming the motor excitement of acute and chronic mental disorders in their talkative, active, noisy, destructive, or violent phases. In this class of cases the range of doses may sometimes have to be greater than in the treatment of insomnia: from gr.  $\frac{1}{10}$  to gr.  $\frac{1}{60}$ . He has seldom been obliged to give so much as gr.  $\frac{1}{60}$ , and has rarely had to give more than one dose in twenty-four hours. As an occasional exception, a patient has been found whose excitement has successfully resisted a full dose; but it must be remembered that some cases of chronic mental excitement have been dosed with varying success through a period of years, until a peculiar condition of resistance to and toleration of remedies of this class has become established. Where a large number of excited patients are congregated, even though they may be classified with care, there are a few who seem to be the cause of most of the general disorder and confusion: reduce these few to a condition of comparative quiet, and the larger but less aggressive element remains tranquil.

The physiological effect of a full dose of hyoscine, say gr.  $\frac{1}{60}$ , is manifested within

twenty minutes. These are—brief, transitory bewilderment; marked interference with co-ordination; widely-dilated pupils; slow, regular, very full pulse; dryness of the throat; relaxation of the vocal cords; very slow, full respirations, sometimes becoming Cheyne-Stokes; marked suffusion of the face and of the general surface of the body; a slight rise in temperature; and free diaphoresis, which does not seem to restore normal temperature. There is general muscular relaxation and a sense of wretchedness. Sleep usually follows, which continues from one to five hours, if the dose is given in daytime and the patient is not put to bed. This amount, administered at night, would be followed by sleep lasting for eight or ten hours. The mydriatic effect is rather transient, but usually persists through an entire day. The pulse is slowed about twenty beats per minute, and this effect gradually wears away during eight or ten hours, and is often followed by a very variable period of pulse-acceleration, which seems to be simply a reactionary hastening of the pulse to restore the disturbed balance of the circulation. The normal rate of respiration is gradually restored through a period ranging from three to five hours.

The rise in temperature is not an invariable result, and is frequently small,—seldom exceeding one and a half degrees,—and the balance of temperature is usually restored within two or three hours. Dryness of the throat often persists through an entire day. Suffusion of the surface of the body is usually transitory. In moderate and in small doses the effect is, of course, proportionate to the amount employed; but the same general symptoms are present, and the patient is quieted accordingly. Interference with the appetite is sometimes observed. It does not seem to act upon the bowels nor upon the kidneys.

Hyoscine is not always well borne; occasionally the following symptoms have followed the use of a moderate dose: nausea, vomiting, anorexia, dysuria, syncope, with small, rapid, irregular pulse, and with symptoms of partial paralysis of the pneumogastri-  
cs.

Is it best to give the remedy hypodermically or by the mouth? It acts almost immediately and in rather less dose by the former method; yet Dr. Wetherill prefers usually to give it by the mouth, as it acts very promptly, when taken into the stomach, even in very small doses, and this method offers no shock to an excited or timorous patient.

## ON SYMPATHETIC OPHTHALMIA.

DEUTSCHMANN instituted a series of researches with the view to determine the pathogenesis of sympathetic ophthalmia (*Gräfe's Archiv*, xxxi. p. 277), and came to the conclusion that the inflammation was transferred from the affected to the healthy eye by way of the optic nerve and its investments, and that micro-organisms are the actual carriers of the infection. He succeeded by injecting the staphylococcus pyogenes albus into one eye in producing a sympathetic inflammation in the other. In five eyes extirpated a long while ago on account of sympathetic ophthalmia he found in the vitreous body numerous cocci and bacilli, and in four other eyes removed for the same cause he detected at once the staphylococcus pyogenes aureus and albus. Deutschmann does not believe that we have to deal in these cases with specific pathogenic microbes, but that there exist a number of various micro-organisms in this affection which, according to growth and propagation, may serve to transfer the inflammation from the affected to the healthy eye.

## A NEW GALACTAGOGUE.

At a recent Medical Congress, in Naples, PROFESSOR PROTA-GIURLEO called attention to the *Ditana digitifolia*, a Mexican plant, as possessing remarkable galactagogue properties (*Phar. Post*, November 28, 1885). He mentioned several cases reported in Italian journals in which the administration of an infusion (of what parts of the plant is not stated, nor the strength) to nursing women had exercised a marked influence upon the milk-glands, inducing a considerable secretion of milk, even in cases where it had been nearly or entirely suppressed. Ethereal tincture of the flowers of *Ditana digitifolia*, made into a kind of elixir with syrup, is said to have been brought out by an Italian pharmacist under the name of "galattofore." The flowers, and especially the stamens, are in addition credited with sudorific properties.

Professor Giurleo has also directed attention to the *Rhamnus alaternus* and *Ligustrum vulgare* as plants possessing properties antagonistic to those accredited by him to *Ditana digitifolia*. The property of *Rhamnus alaternus* in diminishing the secretion of milk was reported about forty years since, though since practically overlooked, and Professor Giurleo now states that he has found the *Ligustrum vulgare*, though so far removed

from it botanically, to possess exactly similar properties. The drug is said to be best administered as an infusion of 3 grammes (45 grs.) of leaves in 150 grammes (5 oz.) of water, twice in the course of twenty-four hours, this dose being repeated for several days.—*Pharm. Journ. and Trans.*, December 25, 1885.

## ANTIPYRIN AND THALLINE.

The result of a long series of observations which were made at the clinic of Prof. Eichhorst, in Zurich, has been published in detailed form in Ziemssen's *Archiv für Klinische Medizin*, by DR. SARA WELT. In the following article will be given a short synopsis of the most important conclusions reached.

*Antipyrin*.—The number of cases consisted of 122 patients, of which 62 were males and 60 females. Among these were 88 cases of typhus abdominalis, 10 of pneumonia fibrinosa, 11 of phthisis pulmonum, 3 of erysipelas facie et capitis, 3 of rheumatismus articularis, 1 of rheumatismus muscularis, 2 of diphtheria faucium, 2 of endocarditis ulcerosa, 1 of variola, and 1 of metritis. The total number of single doses amounted to 1134. The largest quantity which was given any one patient in the course of the disease was 165 grammes (5½ oz.) within thirty days. During the commencement of the observations the author confined herself to the directions of Filehne, and prescribed 2 grammes (30 grs.) for each of the first two hours, and 1 gramme (15 grs.) for the third hour, provided the fever had not already abated. Vomiting was by no means rare, though this sometimes—not in the majority of cases—was prevented by adding opii 0.01 to 0.02 ( $\frac{1}{10}$  to  $\frac{1}{20}$  gr.) to the powder.

Soon, however, the author began to give antipyrin per rectum, and then ceased giving single doses as before mentioned, but chose a dose of such quantity as would suffice to cause complete apyrexia; that is, the object, generally speaking, was to determine during the first and second day what may be termed the individual dose of antipyrin which would bring about the above result. She began by prescribing 2 grammes of antipyrin, giving children but 1 gramme. Often a complete and prolonged effect was obtained by this. On the succeeding days the quantity was increased to 3, 4, and, if necessary, to 5 and 6 grammes. These last-named doses, however, were not frequent, but in one case a single dose of 8 and 10 grammes was given. The powder, dissolved in 50 grammes (nearly 2 oz.) of tepid water,

was injected by a small glass syringe into the rectum. No threatening symptom was ever observed from administering antipyrin in this manner. The relation of what may be termed the individual dose to this long course of observations was such that in twenty cases a complete effect was secured with 1 gramme of antipyrin. The temperature fell to and below 38° C. (100.4 F.) sixty-two times. An almost complete effect—by which is meant a fall in temperature to between 38° and 38.5° (100.4° to 101.3° F.)—was secured with 1 gramme of antipyrin nineteen times in eight cases. But it should be stated that doses of 1 gramme were almost exclusively given to children, and doubtlessly these frequent effects may be ascribed thereto, though doses of this quantity may suffice for adults.

Doses of 2 grammes secured complete effects, in seventy-two cases, four hundred and ninety times; almost complete effects, in thirty-three cases, seventy-one times. Doses of 3 grammes secured complete effects, in sixteen cases, fifty-three times; almost complete effects, in six cases, six times. Doses of 4 grammes secured complete effects, in twenty-six cases, seventy-four times; almost complete effects, in nine cases, fourteen times. Doses of 5 grammes secured complete effects, in five cases, sixteen times; almost complete effects, in two cases, three times. Doses of 6 grammes secured complete effects, in ten cases, nineteen times; almost complete effects, in one case, twice.

A dose of 8 grammes achieved an almost complete effect once in one case. A dose of 10 grammes resulted in a complete effect once during one case.

The last-named two doses were prescribed for a patient in the eighth month of pregnancy, suffering from pneumonia fibrinosa, without any disagreeable consequences. The movements of the child, which were very restless at times of fever, became very quiet, and it was noticed that whenever antipyrin was prescribed for gravid women it had a quieting influence upon the child's movements.

After two doses of 2 grammes each, complete effects were secured, in thirty-three cases, fifty-eight times; almost complete effects, in twelve cases, fourteen times.

After three doses of 2 grammes each, complete effects were secured in eleven cases, fourteen times; almost complete effects, in three cases, three times.

After four doses of 2 grammes each were obtained complete effects, in three cases, four times. After two doses of 4 grammes each, complete effects, in three cases, three times;

almost complete effects, in one case, once. Seventy single doses of antipyrin were without any effect.

Regarding the before-mentioned individual doses, it was noted that they may often vary for the individual. Persons whose condition responded promptly to small doses of antipyrin suddenly continued to have fever, in spite of taking the dose which had until then proven effectual. Dr. Welt particularly lays stress upon these observations in connection with patients suffering from erysipelas and pneumonia. As long as the anatomical process remained stationary the determined individual dose remained unchanged; as the disease progressed an increase in the quantity of antipyrin became necessary. Occasionally an antifebrile effect was not observed, in spite of very large doses.

Regarding the duration of the antifebrile effect of antipyrin, it was observed that this effect continued as much longer as the quantity of the individual dose required to abate the fever became larger. Dr. Welt frequently made this experiment: she gave patients whose individual dose had been determined double the quantity, and observed that in a large majority of cases the effect, especially in reference to its duration, was not only again as long, but frequently still longer.

Among one hundred and twenty-two patients for whom antipyrin was prescribed, the author noticed the exanthema following its use thirteen times, or 10.6 per cent. As to males and females, it was observed in the former six times, or 9.6 per cent., and in the latter seven times, or 11.6 per cent. With the exception of one case, it invariably followed with patients suffering from typhus abdominalis. Possibly patients suffering from gastro-duodenitis may have a tendency to exanthemata upon taking antipyrin. As a rule, a prolonged use of antipyrin was required to produce an exanthematous eruption; but in one case such an eruption broke out twelve hours after taking a dose of 6 grammes. It seems that women are more inclined to this exanthema than men.

Concerning the character of this exanthema, it was observed that in almost all cases it was a roseolous exanthematous efflorescence, very much like an urticaria. In three cases a hemorrhagic exanthema appeared, and Dr. Welt found that very small miliary, thickly-sown hemorrhages favored the inguinal region, and generally the flexor sides of the large joints of the body.

In the author's observations she found that

the eruptions of this exanthema took place without the patient suffering the least pain; and in the further course of the disease most of her patients did not complain of the exanthema, although in one case the patient experienced itching in the affected locality. In several cases she observed desquamation of the skin. Contrary to the experience of other observers, exanthema in the face was also noted. Sometimes the entire face was bloated; the rima palpebrarum reduced on account of œdema of the eyelids. In some cases the author noticed a heightened redness of the mucous membrane of the lips,—not so much of the mucous membrane of the cheeks,—so that it would suggest an antipyrin exanthema. Still, it seems that this occurs rarely. Likewise she found erythematous patches on the palmar surface of the hands and feet. Regarding the duration of the exanthema, it had a tendency to assume a subacute course. Only in two cases had the exanthema faded by the fourth day. Generally traces of it were found in the second week, and sometimes at the end of the second week.

In summing up the effect of antipyrin, Dr. Welt found that the temperature would begin falling immediately upon taking it, and continue to do so until normal temperature was reached. Not seldom it would fall to a subnormal degree. It was observed that the temperature would rise after taking antipyrin, and not begin to fall until after the lapse of half an hour. The pulse, however, does not keep step with the temperature. Sometimes it would remain unchanged, or become slightly less frequent. Sometimes a temporary increase in frequency would succeed the fall in temperature. It is almost a rule that even with determined individual doses of antipyrin the temperature may not only become normal, but subnormal, though no clearly defined cases of collapse were met with. During the fall in temperature she noticed at first a slight perspiration, which becomes more profuse, sometimes so much so that change of linen becomes necessary. Simultaneously a slight cyanosis makes its appearance on the back of the forearm and hands, which may become very intense.

Often the extremities were cold. The entire appearance of the patient doubtless resembled one of collapse, but the feeling of collapse was absent, nor could any loss of strength be determined.

In the recurrence of rising temperature of patients whose fever had abated the author observed six cases of chill,—almost always

chilliness, never a clearly-defined chill. Finally, there are no specific effects of antipyrin.

Briefly, then, according to her experience antipyrin is an excellent *symptomatic* remedy, but it is without influence on the disease itself.

*Thalline.*—Experiments with this new remedy were made on seventeen feverish patients, and Dr. Welt was soon convinced that, like Jaksch, and, later on, Alexander, she had found in thalline a powerful and generally effective febrifuge, because, among one hundred and forty-one doses, the febrile effect was wanting in but *three* patients. In the mode of administration she followed the directions of Jaksch. She usually began by giving the patient a dose of 0.25 (4 grs.) thalline, and continued giving the quantity hourly until the temperature became febrile. The largest dose was 1.5 grammes (22 grs.) within six hours. The general characteristics of the fall in temperature after the use of thalline resemble closely those noticed after the use of antipyrin,—usually first a fall in temperature, then profuse perspiration takes place, but not so profuse as after taking antipyrin. Likewise after the use of thalline at first an erythematous and then cyanotic discoloration of the skin was noted in the face and on the extremities. The author noticed frequently occurrence of chills upon the rise of the abated temperature. Their intensity varied: not rarely a severe chill took place which lasted over two hours. Among one hundred and forty-one single doses the occurrence of chills was observed seventeen times, or 12 per cent.; among eleven hundred and thirty-four single doses of antipyrin, six times, or 0.5 per cent. Vomiting was observed ten times, or 7.1 per cent., in comparison with antipyrin, among eleven hundred and thirty-four doses, one hundred and fifty-three times, or 13.5 per cent., and in this respect antipyrin is inferior to thalline. In one case, after using thalline, the urine, which at a high temperature had shown no traces of albumen, was not only more highly colored, but contained albumen, which did not disappear until thalline was stopped. This was not experienced in the use of antipyrin. Diarrhœa was frequently observed after the use of thalline. Shortly after the first doses the stools were of a striking watery character. This was not observed in connection with antipyrin; in fact, it was found that antipyrin had a kind of astringent effect. In reference to the frequency of the pulse, the author found not rarely that, as with antipyrin, the pulse became more frequent as the temper-

ature fell, soon, however, to conform more or less with the fall in temperature in the decrease of beats. In the occurrence of chills at the rise of the abated temperature thalline reminds one of kairine ; but unlike kairine, inasmuch as the patients did not become uneasy ; in fact, in spite of the chill, they were, without exception, not uncomfortable.

Therapeutically speaking, the author would place thalline between kairine and antipyrin, with more of the good qualities of antipyrin. Still, we cannot pronounce them equally good, because, though thalline may be a more effective remedy to reduce high temperature to the normal, its effect is not so lasting. Thalline can likewise only be regarded as a symptomatic remedy.

#### EXTERNAL USE OF LOBELIA INFLATA.

DR. V. N. REICHARD highly recommends the use of lobelia inflata (*Med. Times*, December 12, 1885) as a local application for indolent sores, chronic erysipelas, and especially in incised wounds, in which latter class of cases it acts as a hæmostatic and astringent. The mode of employment of lobelia for this purpose in cases of incised wounds, no matter how great the hemorrhage, provided, however, it does not require a ligature, is to bring the edges of the wound together, and to hold them for a few moments, while a pledget of cotton, wet with tincture of lobelia, is applied. Dr. Reichard says that the hemorrhage will then cease and the parts adhere, and, although lobelia may not be a germicide, it will so entirely close up a wound as to render it perfectly aseptic.

#### NUX VOMICA IN THE TREATMENT OF PROLAPSUS OF THE ANUS.

M. SCHWARTZ (*Les Nouveaux Remèdes*, December 1, 1885) has employed the extract of nux vomica with success for the last ten years in the treatment of prolapsus of the rectum, not only in children, but even in adults in whom this condition had been neglected and had passed to the chronic stage. He administers it in a dose of  $\frac{3}{4}$  to 1 grain dissolved in an ordinary tumblerful of water, of which 7, 8, or 10 drops are taken every four hours. He claims that in twenty-four hours the prolapsus will have disappeared. For children the dose is 5 drops, and for infants, up to two years of age, 2 to 3 drops. In order to prevent recurrence he advises the continuance of this medicine, in two doses daily, for a week after the

cure. If the prolapsus is of long standing, and does not yield to this treatment, he adds to the above 60 grains of the extract of rhatany.

#### DISINFECTION BY HEAT.

Among the various means of destroying the infectious material by which certain forms of contagious disease are capable of being communicated, the application of heat has long been regarded as one of the most efficient. Modern research having shown that some communicable diseases are connected with the presence of microbes, or living organisms in the blood and tissues, a scientific significance has been thus given to the belief in the efficacy of heat as a means of destroying contagion. From this point of view it has become desirable to investigate the conditions under which micro-organisms are destroyed by heat ; for if the probable inference, that all diseases of the contagious class are similarly referable to such organisms, be well founded, valuable means of counteracting their influence may be ascertained. An elaborate investigation of this subject has lately been carried out by DR. PARSONS, in conjunction with DR. KLEIN, at the instance of the Local Government Board ; and in the supplementary report of the medical officer of that department there is a long report upon the experiments made and the results arrived at. Going back to the earliest recorded experiments on disinfection by heat, those made by Dr. Henry, of Manchester, in the early part of the present century, it appears to have been shown by them, so far as they went, that the contagia of the ordinary infectious diseases are destroyed by dry heat at temperatures below the boiling-point of water. It was found that the activity of vaccine lymph was destroyed by exposure to temperatures ranging from 140° to 192° F. for periods of from two to four hours. Subsequent experiments of the same kind by Dr. Baxter gave a somewhat different result, which was attributed to the shorter periods of exposure to heat in the latter case. The experiments of Drs. Carsten and Coert also showed that calf lymph was invariably sterilized when heated to the boiling-point of water ; but the experiments of Dr. Henry upon the precise degree of heat necessary to destroy the contagia of human communicable diseases other than vaccinia do not appear to have been repeated by subsequent investigators, owing doubtless to the ethical objections to the performance of such experiments on the human subject. Observa-

tions have, however, been recorded from time to time, tending to show that the contagia of the commoner infectious disorders, and those of yellow fever and puerperal fever, do not survive exposure to a temperature of  $212^{\circ}$  F. Davaine ascertained that the blood of an animal suffering from anthrax was disinfected by an exposure for fifteen minutes to a temperature of  $123^{\circ}$ , but that the virus of septicæmia was not destroyed by prolonged ebullition, while in Dreyer's experiments rabbits inoculated with septicæmic blood, previously mixed with water and boiled, were not infected. Later experiments by Koch and his coadjutors have been directed to ascertaining the destroying effect of chemical agents and of heat upon organisms devoid of spores, such as the micrococcus prodigiosus and the bacterium of blue pus and of septicæmia, while, as specimens of spore-bearing kinds, the bacilli of anthrax and those found in hay and in garden earth were chosen.

The general result of the experiments with chemical agents was to show the comparative or entire inefficacy as germicides of most of the substances commonly regarded as disinfectants, such as carbolic acid, sulphurous acid, chloride of zinc, etc. But the spores of bacillus anthracis were destroyed by exposure for one day to the action of aqueous solutions of chlorine, iodine, bromine, corrosive sublimate, permanganates, and osmic acid. They were also destroyed by exposure for longer periods to arsenious acid, chloride of iron, and some other substances. The destructive power of substances in the form of vapor was found in some cases to be increased by elevation of temperature. In the experiments with hot air it was found that bacteria free from spores cannot withstand exposure for one hour and a half to a temperature little over  $212^{\circ}$  F.

Spores of mildew require for destruction a temperature from  $230^{\circ}$  to  $239^{\circ}$  F., maintained for an hour and a half. Spores of bacilli were destroyed only by exposure for three hours in air heated to  $284^{\circ}$  F. The results obtained with steam were strikingly superior to those with dry heat, exposure for five minutes being sufficient to kill the spores of the anthrax bacillus; moreover, the penetration of heat into articles exposed to steam took place far more quickly than when the same articles were exposed to dry heat.

In the experiments conducted by Dr. Parsons and Dr. Klein, hot air, boiling water, and steam at atmospheric pressure were employed as the means of applying heat. The

results obtained with dry hot air were more favorable to its efficacy as a disinfecting agent than those obtained by Koch; and since none of the infectious diseases for the extirpation of which measures of disinfection are commonly required in practice are known to depend upon the presence of bacilli in a spore-bearing condition, it was inferred that their contagia would not be likely to retain activity after exposure of an hour to  $220^{\circ}$  F., and that provided an article, such as a pillow, were heated throughout to that degree, it would not be likely to retain infection. In the experiments with boiling water the anthrax bacillus containing spores was destroyed by exposure for five minutes or less; and it was not thought necessary, therefore, to extend these experiments with the less resisting forms of contagia. The results of the experiments with steam at  $212^{\circ}$  F. were conclusive as to its destructive power upon all the contagia submitted to its action; and only in one instance was there room for suspicion that the disinfection was not complete when the highly resistant anthrax spores were exposed to steam for five minutes only. The concurrence of these results with those obtained by Koch, Gaffky, and Söffler is considered to justify the conclusion that the complete penetration of an object by steam-heat for more than five minutes is sufficient for its thorough disinfection. The efficacy of ordinary steam having been established so satisfactorily, it was not considered necessary to make any experiments with steam at higher temperatures, or under pressure.

As regards the practical application of this method of disinfection, it was necessary to ascertain how the required degree of heat may best be made to penetrate through bulky and badly-conducting articles, such as bedding, clothes, etc., for the disinfection of which heat is especially employed. It was further necessary to learn whether such articles could be submitted to the required degree of heat without injury; for if that is not the case the method of disinfection by heat would not present much advantage over that of total destruction by burning. Although the outer casings of such articles as pillows and mattresses coming into contact with the body of a patient are more liable to become soiled with infectious material than the inner parts, and are for that reason more likely to convey infection to other persons, it would not be safe to assume that the power of infection was confined to these external coverings, and for that reason it is necessary that the

heating should be made to permeate every part of the articles to be disinfected for a sufficient time to destroy all infectious material with which they may be impregnated. Bedding, blankets, etc., are of all things the most difficult to deal with, and even thin layers of badly-conducting materials offer considerable resistance to the penetration of heat. This is a reason why the application of heat through the medium of dry air to such articles is less readily efficacious than the use of steam; and in the experiments made in this way it was found that a satisfactory result could be secured only when the application of heat was continued for many hours. When steam is employed as the heating medium a better result is obtained, mainly in consequence of the large amount of latent heat contained in steam; partly, also, because its presence prevents the cooling effect of the evaporation of any moisture in the articles operated upon, and partly because the moistening of the dry porous substances by condensed steam is attended with disengagement of heat. The use of steam under high pressure is considered by Dr. Parsons to be an additional advantage in promoting the penetration of heat, though the opinion is not in accordance with the views of Koch. Another very difficult point to be considered in connection with this method of disinfection is the liability of articles to injury by exposure to heat. Even partial deterioration, by no means amounting to actual spoiling, of articles disinfected by heat might become a source of serious embarrassment to sanitary authorities by rendering the owners of such articles unwilling to submit them to disinfection. On this important point the report does not profess to offer a precise decision, but merely to set forth some of the general principles to be kept in view for guidance, according to the materials operated upon and the particular kind of apparatus employed. The chief modes in which injury may be caused are scorching or partial decomposition of organic textures, indicated in its incipient stages by changes of color and texture, as well as by brittleness; weakening of strength; fixing of stains so that they will not wash out; melting of readily fusible substances, such as wax, varnish, etc.; alteration of the color, gloss, etc., of dyed goods; shrinkage and felting of woollen materials, and wetting. These effects differ somewhat, according as steam or dry heat is employed. The general conclusions as to the practical utility of disinfection by heat are summed up in the report as follows: For washable ar-

ticles which will stand boiling in water no other procedure is necessary, due care being taken that infection is not communicated in the removal of the articles. The articles for which a more technical "disinfection" by heat is required are such as will not bear washing in boiling water, such as blankets, rugs, carpets, cloth clothes, pillows, beds, mattresses, furs, and dresses. Articles of furniture with stuffed seats may also require disinfection, as well as rags coming from places where epidemic disease prevails. In such cases the application of steam is the most effectual. Letters may be treated in the same way, provided they are not fastened with sealing-wax. In all cases where steam is used precautions must be taken against undue wetting of the articles to be disinfected by condensation of the steam. Leather articles are at once destroyed by the application of steam, and consequently their disinfection must be effected by careful exposure to dry heat. This very interesting and important report concludes with an extended description of all the different forms of apparatus that have been introduced for the purpose of disinfection by heat, each of them illustrated by drawings to show the mode of construction, and an account of the practical experiments carried out with the assistance of various local sanitary authorities, public institutions, etc.—*Pharm. Journ. and Trans.*, December 26, 1885.

#### ON ADONIDINE.

HUCHARD presented in the Société de Thérapeutique, at a meeting held on December 23, 1885, a series of cardiographic and sphygmographic tracings taken from patients under treatment with adonidine (vide *Gaz. Heb.*, January 1, 1886). Our readers will recall that adonidine is the glucoside of adonis vernalis, and was first extracted by Cervello as an amorphous yellowish extract of a bitter taste. The first experiments with the drug were made by Lesage and Montague. The cardiac frequency was found under its influence to be decreased, and at the same time a peculiar state of ventricular rigidity is induced, the ventricle itself becoming pale and anæmic.

Huchard injected 1 to 2 cg. ( $\frac{1}{100}$  to  $\frac{2}{100}$  gr.) hypodermically into rabbits, and found respiration reduced, the cardiac forces raised, disappearances of paralytic symptoms, fall of temperature, and death ensuing after fifteen to twenty hours. In man the infusion of adonis

vernalis may be given in 4 to 8 grammes (1 to 2 dr.) for a dose, four times daily, or, still better, in pill form, 4 to 5 daily,  $\frac{1}{10}$  of a grain each. Huchard reported several cases in which adonidine had been successful. In one case of interstitial nephritis with galloping heart-sounds, anasarca, and beginning asystole, in which sparteine had been given in vain, adonidine induced a profuse diuresis and an unquestionable improvement in the patient's condition. For some time, however, the drug had to be discontinued, on account of diarrhoea and vomiting which it produced. When the quantity of urine fell off again, the remedy was again exhibited, and again relieved the most urgent symptoms; the diuresis rose two to four quarts daily. At the same time the arterial pressure grew stronger, the pulse more regular and full; the œdema and cardiac frequency receded. In a woman having a mitral affection, but no heart-murmur, the drug produced a very audible systolic murmur. In typhoid fever, where great reduction of the arterial pressure exists, Huchard thinks the drug might be used advantageously to raise the pressure.

#### THE EFFECTS OF COCAINE ON THE CENTRAL NERVOUS SYSTEM.

DR. D. R. BROWER draws the following conclusions from a paper with the above title, published in the *Journal of the American Medical Association*, January 16, 1886:

1. Cocaine in small or moderate doses is a cerebral stimulant, but produces derangement of the digestive and assimilative functions, and diminishes the elimination of waste.
2. The use of cocaine in the alcoholic and opium inebriates is not satisfactory; while it is a more or less perfect substitute, yet its use is attended with greater danger than alcohol or opium.
3. The use of cocaine in mental depression, if we carefully guard against the depressing effects of the drug upon digestion and assimilation, will often give better results than any drug hitherto used.
4. The use of cocaine in neurasthenia is a valuable addition to the treatment.
5. The drug, if administered in large doses persistently, causes a very marked deterioration of the central nervous system, producing a profound cerebral neurasthenia, and may produce such a malnutrition of the cerebrum as to develop insanity.
6. Cocaine occasionally, in doses heretofore

regarded as small, produces alarming depression of the central nervous system.

#### ON HYPNONE.

LABORDE addressed the Société de Biologie on the 12th of December, 1885, on the new hypnotic, hypnone (*Gaz. Hebd.*, January 1, 1886), and considered especially its physiological action as far as known up to the time. Injected hypodermically into a guinea-pig in doses of  $\frac{1}{2}$  to 1 c.c. (8 to 16 gtt.), hypnone causes a profound torpor which terminates in death. Respiration is at first quickened, but soon grows slow, labored, and asphyctic; the heart's action considerably increased in frequency, registers a progressive diminution of its force. The temperature sinks rapidly several degrees (C.). In this animal the somniferous dose is at the same time a fatal one. In a dog hypodermic injections of even 3 c.c. (48 gtt.) produce no sleep; brought into the stomach the drug causes vomiting, but likewise no somnolence. Intravenous injections, however, cause complete and instantaneous anæsthesia and a profound sleep; the pupils dilate, the reflex irritation is lowered, arterial pressure falls, probably on account of the decreased activity of the cardiac muscle, the heart-sounds grow more and more faint and inaudible, and respiration grows asphyctic.

In the meeting held on the 19th of December, Laborde delivered another essay on hypnone, and discussed especially the mechanical and physiological mechanism of the circulatory and nervous phenomena produced by the drug. He regarded a diminished excitability of the pneumogastric and a depression of motor centres in the brain as the chief factors of the physiological influences of the drug. Therapeutically, the drug appeared in his view as actually too dangerous to receive an unqualified commendation.

GRASSET, of Montpellier, remarked that the drug is best exhibited as an inhalation.

#### CHRONIC POISONING BY BISULPHIDE OF CARBON.

At a recent meeting of the Medical Society of London, DR. W. B. HADDEN read a paper on a case of chronic poisoning by bisulphide of carbon (*The Lancet*, January 2, 1886). The patient was a man aged 45, who was employed at an india-rubber factory, where he had to inhale the vapor of bisulphide of carbon and chloride of sulphur. The main

symptoms were loss of power over the extremities, with a tendency to stagger and inco-ordination generally. He had no defect of vision. His fellow-workman had also been under treatment at St. Thomas's Hospital with general muscular weakness and visual defect with color-blindness. The case was reported in the "Ophthalmological Transactions," vol. v., in which the report of the special committee would also be found.

DR. RICHARDSON said that pure bisulphide of carbon was a powerful anæsthetic, and caused painless death. He had frequently used it to destroy dogs. Delpech, in 1866, was the first to describe the effects of chronic poisoning by this agent. This form of poisoning was more common in France, but even there it had diminished with improved hygiene of the workshops.

#### *SCHULTZE'S SWINGING MOTIONS TO REVIVE ASPHYCTIC NEW-BORN CHILDREN.*

PROF. SCHULTZE, of Jena, attracted the attention of the entire medical world when, a good many years ago, he first published his now famous mechanical method to revive new-born children laboring under asphyxia. The question whether a new-born child be actually still-born, and no vital energy be present at all, or whether the spark of life be really latent, ready to set agoing the functional mechanisms under appropriate stimulation, belongs to the most important problems that present themselves to the practitioner.

From a description of Schultze's swinging motions appearing in the December issue of *Schmidt's Jahrbücher* we make the following translation :

The child is caught by its shoulders, so as to place the thumb on the anterior surface of the thorax, the index finger in the axilla from behind, and the other three fingers of each hand transversely across the back, thus supporting the drooping head on the ulnar edges of the palmar aspects of the hands. Then spreading asunder one's feet and inclining the head somewhat forward, the child is swung with outstretched arms upward to an angle of 45°; then the swinging is stopped. The entire weight of the child rests at this moment on the thumb of the physician, which is pressed against the thorax of the child. This position occasions a considerable compression of the thoracic viscera not only from the diaphragm, but also from the chest-walls. This passive expiration occasions often a discharge

of the aspirated fluids through the respiratory channels. Then the physician moves his arms downward, and swings rapidly the child toward his feet, whereby the thorax of the child is widened. As the child hangs by its upper extremities, and the sternal ends of the ribs are fixed, its own weight goes to elevate the ribs, while the diaphragm recedes on account of the shock imparted to the abdominal cavity. This equals a mechanical inspiration of a considerable importance. After a few seconds the child is again swung upward, and the aspirated fluid is then usually discharged.

#### *THE INDICATIONS FOR LAPAROTOMY IN PENETRATING STAB AND SHOT WOUNDS OF THE ABDOMEN.*

At a stated meeting of the New York Academy of Medicine, Section on Surgery, held December 14, 1885, after a brief introduction by the chairman, Dr. Stephen Smith, the discussion was opened by DR. JOSEPH D. BRYANT (*Boston Med. and Surg. Journ.*), who said that he who unconditionally asserted that any operation or method of procedure should be resorted to in all cases, even though it were a measure accepted by the profession generally, took a position that required, in justice to the profession and the patient, that all operators should be competent and well equipped for its performance. Especially was conservatism necessary in the advocacy of an operation, the propriety of which, as yet, was spoken of by many with doubt commingled with dread. But a short time had elapsed since the late Prof. James R. Wood had in this hall opposed laparotomy in the cases under consideration in what were generally recognized at that time as sound practical principles; and though marked advancement in all surgical procedures had taken place since then, a sufficient period had not yet elapsed, nor were the members of the profession well enough informed on the details of the entire operation for any one to proclaim boldly that laparotomy should be performed in all cases. Few indeed were the hospitals in the city of New York which could immediately after the accident offer the recognized theoretical, and many of the practical facilities necessary to despatch and cleanliness in operating; not to mention other circumstances bearing on the success of the operation. How much less properly prepared for the performance of laparotomy would the unfortunate patient find the members composing the great mass of the profession!

There were three questions which he thought it well to consider, namely: 1. Should laparotomy be performed in any case? 2. Should it be performed in all cases? 3. When contemplated, should it be done immediately after the accident? In regard to the first, he went on to say that it could not be denied that laparotomy in connection with various abdominal growths was a fully established operation, and the results attending the invasion of the abdominal cavity by numerous operators both at home and abroad plainly attested the expediency of the measure in connection with such growths. There was no proof, so far as he knew, that the peritoneum of the male was not as tolerant of manipulations as that of the female. The excellent success of Billroth and many others, so far as immediate results were concerned, from operations on the stomach, pylorus, gall-bladder, spleen, kidneys, etc., of both sexes, fully showed that intolerance of the peritoneum to manipulations could not be considered a rational objection to the operation of laparotomy for penetrating abdominal wounds. These operations showed also that neither could the length of time required nor the extent of raw surfaces resulting in this variety of laparotomy be urged as objections to the procedure.

Among the practical elements which at the present time entered into a case of laparotomy for penetrating wounds, but which did not exist, or, at all events, exert an equal force, in laparotomy for other common causes might be mentioned the following:

1. A doubt whether the abdominal viscera were injured. This doubt could exert but little influence, since the signs and symptoms of visceral penetration were as pronounced as those relating to other conditions in which laparotomy was deemed advisable. Moreover, an exploratory laparotomy would enable the operator to settle the question of penetration.

2. Existing shock. This element was almost unlimited to those cases of laparotomy which were to be done for penetrating wounds. The shock was due either to loss of blood, to injury done the parts, or to both combined. He believed it to be an established fact that when severe shock followed immediately after the injury, it was due in the great majority of cases to loss of blood; and if this were the case, the indication was to check the hemorrhage at once. An exploratory laparotomy would decide this question.

3. Unfavorable surroundings of the patient.

This element, like the second, was limited to laparotomies for penetrating wounds. It included the surroundings of the patient at the time of the injury, the removal to his home or to a hospital, and the absence of proper preparations for operating in accordance with the best recognized methods of procedure in such cases. It would be impossible to entirely avoid these contingencies; but their dangers could be greatly lessened by caution in moving the patient, by taking him to a suitable hospital instead of to his own home, and by increased familiarity on the part of the profession with all the details pertaining to the operation of laparotomy under the circumstances.

4. Unskilled operators. By this he said he meant that the surgeon in charge of the case might not have had his attention forcibly drawn to the details of the operation, which was recognized as having an important bearing on the prognosis of such cases. More particularly would he find himself in this position if he had previously looked on the operation with a disfavor bred of prejudice, instead of the result of patient toil and observation. This element could be entirely overcome if the members of the profession would but devote an ordinary amount of attention to the matter.

5. Greater exposure of the abdominal cavity and its contents. The great care necessary in order to find out and to remove from the abdominal cavity all the blood and extravasated intestinal contents, to check hemorrhage, and also to detect all the points of injury, required that the intestines and the omentum should be thoroughly examined by a preconceived method, rather than by the rough handling associated with illogical haste.

6. Existence of hemorrhage. In visceral perforation, intra-abdominal hemorrhage was necessarily a constant feature. The vessels of the omentum and of the intestines, especially the former, bled with a pertinacity which was unusual in those of other portions of the body, owing, it was thought, to the walls of the vessels being loosely supported by the surrounding tissues, also to the fact that they seemed to possess in a much less degree the inherent attributes which ordinarily enabled the natural forces of a vessel to check hemorrhage, namely, contraction and retraction. The suspicion of the existence of much intra-abdominal hemorrhage was enough to indicate the making, at least, of an exploratory incision, by which means its existence could be positively diagnosticated; when, if neces-

sary, the incision could be extended, bleeding points checked, and blood-clots removed.

7. Extravasation of intestinal contents. This was a part of the history of penetrating abdominal wounds, and constituted an occurrence which was most to be dreaded by the surgeon.

Dr. Gross asserted that no case had ever been known to recover in which fæcal matter existed in the abdominal cavity; therefore fæcal extravasation was the strongest of the indications of laparotomy,—offering, as it did, the only means of recovery.

8. The greater difficulty of cleansing the abdominal cavity. If blood and intestinal contents had been generally diffused, the cleansing of the abdominal cavity was more tedious and difficult, and also of more importance than in laparotomy for other causes; but the thorough performance of this duty, at least so far as the intestinal contents were concerned, appeared to be the only means of saving the patient's life. As to blood, no one could tell the amount that might remain, and yet recovery occur.

In Dr. Bryant's opinion, laparotomy was a justifiable operation, but it was not to be attempted, even in so-called favorable cases, unless the operator could avail himself of many of the recognized means of procedure necessary to control the shock of the operation, and was sufficiently familiar with its steps to accomplish the work with accuracy and despatch.

Leaving the second interrogatory, should laparotomy be performed in all cases, to be discussed by others, he passed on to the third. When contemplated, should laparotomy be done immediately after the accident? Assuming all things to be equal, he thought that it should be done at once, or, at least, as soon as the necessary preparations required to insure a fair prospect of success could be made. There should first be an exploratory incision, followed, if the condition of affairs warranted it, by the actual laparotomy. In the former, the incision was made in the median line, so situated and of sufficient length to expose to view the probable seat of the internal injury. The surgeon could then, in the great majority of instances, determine if penetration of a viscus had taken place, and if hemorrhage or intestinal extravasation existed. If the patient was in danger from immediate hemorrhage, the blood in the abdominal cavity could be seen through the incision.

Does the exploratory incision expose the patient to unusual danger? The large number

of successful laparotomies, both in this country and abroad, seemed to him to argue this question in the negative; and if this was true, he said, all that was possible was gained, while but little could be lost from the exploratory incision.

DR. J. W. WRIGHT said that he was not prepared to take the ground that all cases of penetrating wounds of the abdomen were to be treated by laparotomy. As regards gunshot wounds, it would be found that the large or small size of the missile, as well as the velocity of the latter, made a great difference in the severity of the injury. For example, he did not believe that the twenty-two calibre bullet, or the ordinary bullet of about twenty grains' weight, behind which there was but about five grains of powder, was calculated to do much mischief. As a rule, such a bullet lodged in the abdominal walls, but even if it did penetrate the cavity, and pass through a knuckle of intestine, the opening made by it was so small that an erosion of the mucous membrane was caused, which would be sufficient to prevent the extravasation of fæcal matter, while the hemorrhage would be but trifling. If, then, he were called to such a case, and there were no symptoms specially calling for laparotomy, he certainly would not perform the operation. But if, on the other hand, he was called to a case in which the injury had been inflicted by what is known as an "express charge,"—a forty calibre bullet, weighing two hundred and seventy grains, with one hundred and ten grains of powder behind it,—he would expect to find abundant indications for its performance. Even in the absence of symptoms, he would consider the case one for immediate laparotomy, for he would feel very sure that if such a missile got into the abdominal cavity at all, it would cut and tear everything that came in its way.

In stab wounds, he said he would not perform laparotomy in many cases, even if he knew that the wound was a penetrating one, or even if the omentum was protruding. In this connection he mentioned the case of a drunken sailor, who stabbed himself in the abdomen, and when a portion of the omentum protruded through the wound, caught hold of it, and dragged it still farther out. Yet the man recovered perfectly, and that without being laid up for an hour. On the very day that he received the injury he went to sea, and in the course of a week the protruding omentum sloughed off, after which he had no further trouble. He also mentioned another somewhat similar case at Bellevue Hospital.

As to the matter of diagnosis, it was difficult to say in every case whether the peritoneum was wounded or not. In many instances there was well-marked shock, simply from the force of the blow, particularly if this was in the neighborhood of the epigastrium. If the shock was extreme and protracted, however, it was probable that the abdominal cavity had been penetrated. In the second place, the occurrence of meteorism indicated damage to the viscera. Thirdly, the protrusion of the gut through the wound proved nothing as to whether the gut itself had been injured or not. This was shown, however, by the escape of the intestinal contents. He thought, therefore, that we should be careful how we state that laparotomy is called for in every case.

DR. R. F. WEIR said that he did not feel in a position to say that penetrating stab wounds of the abdomen were necessarily accompanied with injury of the intestines or abdominal viscera. Unless, in any case, there were symptoms indicating the presence of such complications, the surgeon had only to watch the patient carefully. In regard to gunshot wounds, there was a different state of affairs, and for his own part he had a somewhat greater respect for the capacity for injury of the small pistol balls than Dr. Wright felt, since he had known them to penetrate the abdominal cavity and do a considerable amount of mischief. As a rule, one of the indications was to explore the wound under any circumstances, and he thought that statistics clearly proved that every gunshot wound of the abdomen, at short range, should be carefully examined, in order to see whether or not it penetrated the cavity.

The question of hemorrhage always came up in connection with the existence of shock, and it was often impossible to determine off-hand in any instance whether the patient was suffering from the shock of the injury or of extravasation, or from the shock of hemorrhage. He had learned from the experience of two sad cases that delay might prove fatal (although if the shock was not due to hemorrhage, the chances of success with laparotomy would be greater after it had passed off), and, therefore, he agreed with Dr. Bryant that it was best to make a small exploratory incision in every case where it was impossible to decide whether the shock was due to hemorrhage or not. He did not agree with Dr. Bryant, however, that the small opening would show whether there was much bleeding or not. The blood naturally gravitated toward the lower part of the abdominal cavity, and,

therefore, it was often necessary to pass in a sponge on a stick in order to find out the existence of hemorrhage. Dr. Wright had stated that a small bullet might pass through the intestine without causing extravasation of fæces, or otherwise doing harm, but the very reasons which would make such a wound of less severity, would also be the ones why a laparotomy would be of less severity under the circumstances. For himself, he would proceed to perform laparotomy if the exploratory incision showed that the intestines were wounded, for even if there was no extravasation of fæces, there would almost certainly be an escape of gas into the peritoneal cavity.

DR. A. C. POST thought that in regard to incised wounds, it made a great difference in what part of the abdomen the stab was inflicted. If in the region of the stomach and liver, there was less danger of hemorrhage than if the wound was situated in the region of the intestines. Again, if it was still lower down, it might be below the peritoneum altogether, especially if the bladder was distended at the time. In this connection, he related a case in which a stab wound of the lower part of the abdomen penetrated the bladder, and was followed by a gush of urine, and said that in a case of this kind the safety of the patient, no doubt, was due to the large size of the wound, which gave free drainage, and prevented the retention of the urine in the tissues. A large and direct opening would also have much the same effect as regards extravasated fæces. When there was faecal extravasation, however, he thought that laparotomy should always be performed and the abdominal cavity thoroughly cleansed.

DR. W. M. POLK said that he had had no experience with laparotomy for penetrating wounds, but so far as danger was concerned, the results obtained, both at home and abroad, showed that the exploratory incision was quite a simple affair, comparatively free from danger. It seemed to him, however, that a simple incision, such as those who confined their attention to pelvic surgery frequently had to make, would scarcely be sufficient in the class of cases now under discussion. The gynecologist generally knows about what condition of things he might expect to find, and if a large tumor was present he swept his hand around it, but did not mix his hands much with the intestines. Even in the case of the most extensive growths, the intestines were very little disturbed. This, then, was the point: If a limited exploration were made, there was comparatively little risk, but if it

was necessary to introduce the hand and feel around among the intestines, a great deal was added to the risk. Within the last two or three years he has seen this strikingly illustrated in New York, in Tait's and other similar operations. Formerly, when there were marked adhesions, the intestines were freely handled, and sometimes laid upon the abdomen, and the result was that a fatal result frequently followed. Within the last eighteen months, however, in this same class of cases, the results had been very much more favorable, and this was owing to a different method of procedure. A much smaller incision was now used, and the adhesions were quickly torn away by the hands, without regard to hemorrhage, because the latter soon ceased, and a drainage tube was introduced to remove the blood. Instead of the operation covering an hour or an hour and a half, as before, it now took only twenty or twenty-five minutes. The whole question of danger, therefore, as it seemed to him, would depend on the amount of handling of the viscera required in any given case. So far as the simple opening of the peritoneum was concerned, he thought it was as safe as sewing up the cervix uteri, and attended with really less danger than the opening of the pleural cavity.

DR. W. G. WYLIE thought that the principal cause of shock in the cases under consideration was hemorrhage. The dangers in Tait's and other similar operations, to which Dr. Polk had referred, he believed to have been due not so much to handling of the intestines as to exposure to septic influences from the atmosphere, sponges, etc. According to his observation, the large majority of the deaths were due to septic infection. He would have no hesitation in opening the peritoneum in any case where the patient's life was in question. There was very little danger of increasing shock thereby, and if the shock was very marked, there was every reason to believe that severe hemorrhage was taking place, so that the prompt performance of laparotomy was urgently demanded under the circumstances. After performing operations in the abdominal cavity, he not infrequently washed out the latter with a solution of bichloride of mercury, one to ten thousand, following this with the injection of simple hot water.

#### CHLOROFORM-MANIA.

DR. REHN adds to the literature of chloroform-mania two new cases, which he describes

in the *Centralblatt für Med. Wiss.* of January 2, 1886.

CASE I.—A workingman, 42 years of age, who, up to his thirty-ninth year, enjoyed good health, becomes a morphomaniac on account of violent pains in the inguinal region. And when later even larger doses of morphine failed to afford the desired relief he began to inhale chloroform, and soon accustomed his system to the drug to such a degree that he could consume a wine-bottleful within twenty-four hours. Rehn presents the following clinical index as the sequelæ of the habitual chloroform inhalation of the patient: great depression, irritability, weak memory, lowered intellectual faculty, loss of appetite, emaciation, appearance of gray hairs, œdema, engorgement of the liver, icterus, weak and frequent pulse, and impotency. Withdrawal of the drug made all these symptoms disappear, relapses brought them out again. Later the patient became an alcoholic, and showed psychical alterations such as appear in the beginning of a progressive paralysis.

CASE II.—A lady, 70 years of age, used for thirty years, alongside of large quantities of alcohol and ether, also for variety's sake, chloroform, partly internally, partly by inhalation. The actual quantity of chloroform consumed could not be determined, though it was surely large. In her seventieth year she was seized with grave delirious paroxysms; after their disappearance she "swore off" chloroform and returned to alcohol and ether; of ether she took very large quantities. Rehn infers that chloroform exerts its destructive influence not only upon the red blood-corpuscles, but also upon the nerve and brain substances.

#### HYPODERMIC INJECTIONS OF COLD WATER IN SCIATICA.

DR. D. H. LEWIS, of Lone Pine, Pa., writes to the *New York Med. Record* for January 23, 1886, that he was consulted by a man 60 years of age, who was suffering greatly from sciatica. He had been treated for the past eight weeks by two physicians, and had run through the entire list of anti-neuralgic remedies. Being desirous of trying something which was at least new to the patient, Dr. Lewis determined to employ hypodermic medication, and having no drug handy which he cared to use, he filled the syringe with cold water and injected the fluid deep down behind the trochanter. The following day the patient returned and said that he was feeling much better. The injections were ac-

cordingly repeated every third or fourth day for a period of three weeks, by the end of which time a complete cure was obtained. The writer has since treated a number of cases of sciatica in the same way, with equally gratifying results. He thinks that possibly many of those cases which have been reported as cured by the injection of certain drugs, such as cocaine, might have terminated in an equally favorable manner had simply cold water been used.

#### ON TARDY SYPHILIS.

To the one hundred and four cases of hereditary tardy syphilis heretofore collected, ZEISSL adds in the *Wiener Klinik* (Heft vii., 1885) four new cases which came under his personal observation.

CASE I.—A young man, 18 years of age, whose three younger brothers and mother are healthy; about the father's history no statements could be obtained. Patient showed in his second month of life pronounced rachitic symptoms, in his third year swelling and pain in the knee-joint, in the fourth year a diffuse parenchymatous keratitis, and in his eighteenth year an ulcer on the posterior wall of the pharynx, which healed under mercurial treatment.

CASE II.—A girl, 15 years of age; two elder sisters and brothers and mother are healthy; of her father nothing positive could be ascertained. In her ninth year she had ulcers on the cornea on both eyes, in her tenth an ulcer on the upper lip, which healed in six to eight weeks. In her fifteenth year an ulcer appeared on the cutaneous nasal septum, which penetrated the cartilaginous septum, and later healed promptly under specific treatment.

CASE III.—A boy, 9 years of age; his father contracted syphilis three years before his marriage; his mother and other younger sisters and brothers are healthy. Three months ago a serpiginous ulcer appeared on the chest; the septum narium was suddenly attacked and perforated, and ulcerations broke out on the hard palate. All ulcerations healed quickly under antisiphilitic treatment.

CASE IV.—A student, who had never had a coitus; his parents were believed to be healthy. In his seventeenth year an ulceration appeared on the right wing of the nose, which led to a perforation of the septum. Later, ulcers broke out on the palate and uvula. Injections of corrosive sublimate healed all ulcerations;

relapses occurred, but the specific treatment ultimately produced a permanent cure.

#### SALICYLATE OF LITHIUM IN ARTICULAR RHEUMATISM.

M. VULPIAN has read before the Académie de Médecine a summary of the results of his experiments with salicylate of lithium in articular rheumatism. He states that his experiments indicate that lithium salts are not so poisonous as they are believed to be. Salicylate of lithium is not more dangerous than salicylate of sodium, and can be administered in almost equally strong doses. In acute articular rheumatism, salicylate of lithium relieves the pain which often remains in the joints after the swelling has disappeared; whereas colchicum and salicylate of sodium have no effect. M. Vulpian believes that salicylate of lithium is especially beneficial in fibrous rheumatism. In progressive subacute rheumatism, he has seen salicylate of lithium produce great improvement. Salicylate of sodium has also been successful in such cases, and produced amelioration of the patient's condition; but both greater and more lasting benefit is obtained by salicylate of lithium. In chronic articular rheumatism M. Vulpian has found salicylate of sodium useless, whereas salicylate of lithium has had a marked effect on the joints, which become less swollen and less painful than before the treatment. In order to obtain evident results, 4 grammes (60 grs.), sometimes  $4\frac{1}{2}$  or 5 grammes, must be given daily. Larger doses are followed by toxic symptoms. This drug sometimes induces headache and deafness, but is never followed by the distressing noises which characterize treatment by salicylate of sodium. The headache and deafness disappear quickly.—*British Med. Journal*, January 2, 1886.

#### ON KAWA, A POWERFUL ANÆSTHETIC AND SPINAL DEPRESSANT.

DR. L. LEWIN, of Berlin, the well-known therapist, has the merit of instituting the first experiments with a drug which possesses such distinctly pronounced and powerful physiological properties that its utilization in therapeutics is scarcely questionable. We condense from his highly interesting paper in the *Berliner Klinische Wochen.* of January 4, 1886, the most significant topics. Kawa (Kawa-Kawa, Yakona, Yangona) is the root of *Piper methysticum*, a shrub about three yards high, growing upon the various islands em-

braced under the name of Polynesia in the South (Pacific) Ocean. The shrub is especially found on the New Hebrides, the Sandwich, Feejee, and Samoa Islands, where the use of the plant in some form or other is exceedingly old, and has even been described by the first discoverers of these islands. The kawa-drinks reigned supreme in these islands until the introduction of alcohol; but even to this day kawa is a favored drink with all natives of Polynesia, where kawa-houses exist like our cafés. The preparation of kawa is looked upon by the natives as a solemn and religious affair, which takes place publicly under various ceremonies. Special men and women are selected to chew the root, then it is placed in vessels, water added, and stirred with the hands. The firm masses are then dissolved, and the kawa-drink is ready for use, which announcement is followed by the jumping, dancing, and crying of the assembly, which up to this point has observed silence. The drink is served under prayers in half cocoa-shells, and appears as a grayish, dirty-looking fluid.

The assumption that during the process of preparation a fermentation takes place is erroneous.

Examined chemically the root contains forty-nine per cent. of starch, numerous salts, and a non-nitrogenous body called kawahin. Lewin found besides another body which he termed yangonin. Both these elements, however, have been experimentally proved to be inert. The actual active principle is a resinous mass of a fatty, aromatic taste, pungent and hot like pepper.

*Local Action.*—The kawa-resin increases the salivary secretion, and produces loss of sensitiveness immediately or shortly after application on all parts of the body. Taken into the mouth, one receives the sensation as if the part were burnt. Applied locally to the pharynx, the part grows anæsthetic even in the most sensitive persons. Gradually the increased salivary secretion and the anæsthesia of the pharynx disappear again. Applied to the conjunctiva of cold- and warm-blooded animals, both conjunctiva and cornea lose the power of reaction to even the strongest irritation. The eyeball can be pressed, pinched, and rotated at will without producing a trace of a reaction. In guinea-pigs this condition may last for hours; the eyeball appears more prominent by the regression of both lids, but the pupils retain their normal reactive capacity to light. The return of sensitiveness and reaction is very slow and gradual. If

the kawa-resin be injected into the connective tissue of an animal, anæsthesia ensues in the sphere surrounding the point of injection; mechanical and chemical irritation elicit no reflex response. In a frog the electric irritability was found likewise to be reduced. At and surrounding the point of application no inflammatory symptoms appear, but, on the contrary, marked ischæmia.

*Constitutional Action.*—Ingested, the kawa-drink produces a sensation of comfort, peace, and felicity, and never, as in the case of alcohol, desires of altercation or fight. In the mouth a peculiar, pleasant sensation of coolness is received, and may last for one to two hours. Consciousness and reason are in no way depressed, as in the case of opium, but the mental faculties are rather heightened. Fatigue and hardships appear easier borne under the influence of the drug. If larger quantities of the kawa-drink are ingested, a state of happy freedom of cares and a dreamy consciousness set in. The limbs grow feeble and powerless; gradually the will loses its control over the motor apparatus, rendering co-ordinate movements impossible. The person soon lies down, and gradually falls asleep, or rather in a condition of somnolency.

Nausea and headache, paresis of the extremities, and a nervous trembling are the usual sequelæ of kawa-ingestion after the somnolency has passed off. The system soon grows accustomed to the drug, and the kawa-habit is readily established. It has been asserted that the habitual use of kawa produces pityriasis, though this is questioned by many observers.

*Animal Experiments.*—If kawa is administered to frogs per os or hypodermically, the animals soon grow feeble, the head sinks, and a state of motor incapacity ensues. Though voluntary motion has disappeared, reflex action is still active. Later no response follows upon even the strongest irritation save the electrical one, the efficacy of which is retained longest.

Lewin saw frogs in this condition for nine consecutive days; only the reaction to light and the slow cardiac action still testified to the life of the animals.

A general central paralysis is produced by kawa in a manner that the anterior horns of the gray substance, the motor ganglia, are first attacked, and later the sensible elements in the posterior horns of the gray substance, and lastly the brain ganglia. In birds, rabbits, cats, we obtain the same physiological

effects. At first motion is apparently increased, the animals endeavor to run or fly away; then this desire vanishes, and the animal lies down; temperature, respiration, and pulse fall gradually and simultaneously.

An alcoholic solution applied by the mouth or subcutaneously produces a deep sleep within a few minutes. Part of the kawa-resin is eliminated with the urine. The gastric mucous membrane shows, after death, an ischæmic appearance. These interesting observations clearly demonstrate that in kawa we have to deal with a drug of a most energetic activity, and that its power to produce complete local ischæmia and anæsthesia, reduction of the excitability of the spinal motor apparatus, and besides psychical quiescence, can be unquestionably utilized in therapeutics. Whether the drug has at the same time a diaphoretic, diuretic, or tonic action (to the stomach) has not yet been tested, though it is asserted. The drug is likewise credited to be able to reduce corpulency, and to favorably influence the gonorrhœal process.

Further observations and experiments will no doubt determine the proper therapeutic virtues of the drug, which at all events must be regarded as a valuable acquisition to our remedial resorts.

#### A NEW METHOD FOR THE REMOVAL OF FOREIGN BODIES FROM THE NOSE.

DR. D. BRYSON DELAVAN, of New York, writes to the *New York Med. Record* for January 23, 1886, as follows: "The presence of a foreign body in the nasal cavity is usually attended with marked swelling of the neighboring mucous membrane. Its extraction by any of the means in common use is accompanied with pain, often of great severity, and is often followed by a copious hemorrhage. The swelling offers, of course, a serious obstacle to the extrusion of a hard body, while one which has increased in size from the imbibition of water becomes all the more firmly impacted. Hence, in attempting the removal of the body, more or less laceration of the membrane is likely to occur. The pain, with difficulty tolerated by an adult, causes a child to become in almost every instance unmanageable, so that an anæsthetic is required. The hemorrhage is usually controllable after the lapse of a few minutes, but may, meanwhile, cause considerable annoyance. From our knowledge of the physiological action of cocaine upon the nasal mucous membrane, it is evident that, by its use in these cases, all of the above difficulties may

be overcome; for applied to the nose, the mucous membrane becomes strongly retracted, the sensibility to pain lost, and the blood-vessels exsanguinated. Thus, the calibre of the fossa is greatly widened, the irritation and consequent resistance done away with, hemorrhage prevented, and the removal of the foreign body thereby greatly facilitated. To carry out the method, the occluded nostril should first be cleansed with a spray or a gentle current of some lukewarm alkaline solution, after which a four per cent. solution of cocaine should be applied to the mucous membrane. When its effect has become complete, the extrusion of the body should be attempted by directing the patient to blow forcibly through the affected nostril. Failing in this, it should be drawn out by some suitable instrument. Should the patient be too restless to make this practicable, an anæsthetic may still be administered. In cases of invasion of the frontal sinus or antrum of Highmore by insects or larvæ, cocaine should be applied to the membrane before the administration of chloroform or ether, in order that the canals leading to these cavities may become as patent as possible, and thus the vapor of the anæsthetic be admitted very thoroughly to the intruder's presence. The insensitiveness of the membrane produced by the cocaine will, in these cases, certainly add to the comfort of the sufferer should it be necessary to inject, or still better, to spray the nose with chloroform."

#### ON INFANTILE APHASIA.

PROF. BERNHARDT, of Berlin, presents his views about infantile aphasia in a little pamphlet (*Deutsche Medizinische Zeitung* of January 1, 1886), from which we abstract some salient points.

1. Genuine infantile aphasia is not so common an affection as is commonly believed; about ninety cases are all that are recorded.
2. Its etiological factors are nearly identical with those producing the affection in the adult phases of life, with special consideration, though, of the various characteristics of childhood. The principal causes are reflex conditions after indigestion, entozoa, psychical irritation, infectious diseases, acute and chronic brain-affections.
3. Infantile aphasia is chiefly a symptom of cerebral infantile paralysis.
4. Hemiplegia does not necessarily exist along with aphasia.
5. The affection may disappear spontane-

ously, especially after prudent and systematic physical exercise.

6. The nature of the cerebral lesion in cases of aphasia existing since birth is not known, since no autopsies are recorded. The therapeutics of the affection is little effectual; antiphlogistic measures at first, and later the galvanic current, together with the preparations of iodine and bromine, suggest themselves.

#### CHLORIDE OF CALCIUM AS A THERAPEUTIC AGENT.

We have already referred to this agent in the treatment of scrofulous enlargement of glands, and the views which we have published are confirmed by a recent paper by MR. ARTHUR DAVIES in the *Practitioner*, January, 1886. He reports three cases which he has selected as types of numerous others, which seem to show that chloride of calcium deserves to be ranked as a very useful agent in cases of lymphatic glandular enlargement. The first case may fairly be considered one of lymphadenoma, seeing that the glands were of a stony hardness and had never suppurated. The other cases were of a scrofulous nature, and the exhibition of this drug in these cases was almost always attended with beneficial results. It is useful to note to what extent the drug, cautiously increased, may be tolerated. His method of administering was to give at first 10-grain doses three times a day in 30 drops of water. This, after a week or so, may be gradually increased until even as much as 40 grains may be taken three times daily without producing unpleasant symptoms, with the exception of an occasional scalding sensation in the morning when passing water. For children, of course, the dose must be smaller. Three grains may be given three times daily, and increased to 10 grains. In spite of apparent failure, Mr. Davies advises that this treatment should be persisted in, as possibly twelve months may elapse before improvement takes place. He states that the chloride of calcium is perfectly useless in cases where suppuration has commenced.

#### LEUCOPLACKIA OF THE MOUTH.

The syphilitic element, which especially in cutaneous affections forms so frequently the etiological basis, is no doubt often overlooked, but, *vice versa*, it may happen that the practitioner suspects a specific taint where none exists. Both of these diagnostic errors, which

of course render the treatment of the case fruitless, can be avoided by a careful attention to the characteristic features of the differential diagnosis.

Leucoplackia oris (psoriasis, tylosis, ichthyosis, or keratosis oris) presents, both regarding its locality and its appearance, a sufficient resemblance to the so-called mucous patches (plaques muqueuses) that its distinctive character and symptoms deserve special attention.

DR. SCHECH, of Munich (*Deutsche Medizinische Zeitung* of January 7, 1886) is not certain whether the affection ought to be classed with the chronic inflammations or the neoplasms. In view of its causes, which will be considered below, we do not hesitate to regard leucoplackia as a product of irritation and to place it in the category of chronic inflammations.

Favorite seats of the affection are the mucous membranes of the lips, cheeks, and of the upper and lateral sides of the tongue. We find it consisting of circumscribed reddish patches; the epithelium of the locality grows cloudy and lends to the mucous membrane a milky appearance, as if the place had been touched by the caustic pencil. Later the patches increase in size, become confluent and look marbled. A silver-gray or yellowish-white color is also invariably present.

The complaints of the patients are variable, usually they have a stiffness and impeded motility of the tongue and lips. The affection may limit itself to a couple of months, but may also extend over twenty to thirty years. A complete cure is rather a rarity.

Characteristic of leucoplackia, in contradistinction from the mucous patch, for which it is often mistaken, is the persistency of the eruption and the silver-gray color. The syphilitic patches usually are of short duration, and soon change into ulcerations, and their color is a dirty gray. Besides, the leucoplackic eruption is of a light and yielding consistency, while those of syphilis are hard and resistant. Ultimately, of course, the inefficacy of a specific treatment would reveal its true nature.

The prognosis is unfavorable not only on account of the rarity of a complete cure and the usual length of its duration, but also and chiefly on account of the predisposition to carcinoma which leucoplackia is apt to create. Schech thinks that excessive smoking is the most frequent cause of the affection, though no doubt other agencies, such as the chewing of tobacco, dental caries, habitual use of pungent and acrid victuals, alcoholic excesses, gastric affections, and anæmia may also participate in its causation.

Zeissl strangely regards the affection as produced by corrosive sublimate (not by syphilis), and states that in great smokers it becomes especially marked. Kaposi, on the other hand, brings the disease in direct communication with syphilis.

The treatment must consist in the first place in the removal of all conditions which might be concerned in the causation of the disease. The epithelial layers then have to be removed by an alkaline mouth-wash, preferably the bicarbonate of sodium (10 to 300). In case of existing great pain 10 to 20 per cent. solutions of the muriate of cocaine are indicated. The application of a caustic is to be avoided by all means.

#### TREATMENT OF CHRONIC RHEUMATISM.

At a meeting of the New York Academy of Medicine, Section on Materia Medica and Therapeutics, held December 16, 1885, DR. PETERS, by special request, read a paper on the treatment of chronic rheumatism (*Medical Record*, January 23, 1886). He merely alluded to chronic rheumatisms of the heart, pleura, membranes of the brain and spinal cord, of the eye, ear, throat, kidneys, uterus, etc., and quickly turned his attention to chronic rheumatisms of the joints.

Almost all rheumatisms are connected with an excessively acid condition of many of the secretions and excretions, including the saliva, perspiration, and urine; even the chyme and blood are less alkaline than they should be. Next is the excessive preponderance of fibrin in the blood, and the great and early destruction of red blood-globules.

Alkalies form the natural basis of the treatment of almost all rheumatisms, and the first question which arises is whether the potassium or sodium salts shall be used, or both. As the phosphates and potassium salts naturally predominate in the red corpuscles and in the formed tissues, while the chlorides and sodium salts are most abundant in the serum and plasma, and in all the infiltrating fluids of all the organs of the body, both potassium and sodium may have to be used; and they will so aid and compensate each other that neither will have to be given in excess. In chronic rheumatisms Dr. Peters preferred the milder and more tonic sodium and potassium salts, such as the phosphate of sodium, etc. This is a good and mild laxative when purgatives are required; it also lessens the acidity of the mouth, stomach, and bowels which is apt to be present,

renders the contents of the thoracic duct and the blood more alkaline, and makes the urine and perspiration alkaline. It also lessens the quantity of fibrin in the blood. It is a cooling and slightly antipyretic remedy, and may be used in strong or saturated solution as a local application to chronically swollen joints. In chronic arthritic rheumatism Charcot prefers the carbonate of sodium, of which he gives from 7 to 10 drachms a day, even to old and feeble women, and says he has never seen anæmia or any dissolution of the blood caused by it; on the contrary, his patients even grew stouter and stronger, possibly from the better digestion of sugar, starch, and fat which is caused by this and other alkalies. It also aids in the destruction of an excess of fibrin in the blood, and helps the liver in its great work of destroying fibrin.

Phosphate of sodium is a gentle and pleasant remedy, which may be given in about the way that citrate of potassium and Rochelle salts are usually given; the latter in  $\frac{1}{2}$  or 1 ounce doses when laxation is required, and either in 1 or 2 drachm doses when their alkaline effects are more desired. It neutralizes all acids, even that which is abnormally present low down in the large bowels; and moderates the excessive acidity of the normal acid phosphate of sodium in the urine, and then helps to keep uric acid and the other urates in solution.

But potassium is the natural alkali of the red blood-globules, of the muscles, fibres, and all other formed and solid tissues; and citrate of potassium, and even Rochelle salts, which is a tartrate of sodium and potassium, may reach not only the serum of the blood, but the blood-globules and the parenchymatous structures, when rheumatism is firmly lodged in the latter.

Benzoate of sodium is another non-depressing sodium salt, although it is somewhat antipyretic when given in large doses. It is a solvent of uric acid, increases the elimination of urates in rheumatic lithiasis, and seems not only to convert uric acid into hippuric, but also to liberate a portion of the products of disassimilation in the form of soluble hippuric acid instead of insoluble uric. In delicate and sensitive patients benzoate of sodium may be given with aromatic spirits of ammonia, thus: Sodii benzoatis, 3vi; spts. ammon. aromat., 3vi; spts. myristicæ, 3vi; spts. chloroformi, 3ii; spts. gaultheria, ad 3vi. Dose, 3i to 3ii in water.

The hippurate of sodium has been suggested lately in doses of 5 to 30 grains. It tends to produce soluble urates. A favorite prescription with Granville is: Sodii hippuratis, 3ii;

glycerini, 3vi ; aq. cinnamomi, ad 3vi. Dose, 3ii to 3viii, three times a day.

The tauro-cholate of sodium also holds uric acid in solution, and is said to render the stools characteristically rich in bile without causing purging. The usual dose is 3 to 6 grains, and it is said to be most useful in obese rheumatic patients, in whom the excess of fat slowly melts away. It is doubtful whether it is more useful than purified ox-gall.

The salicylate of sodium is only useful in the acute aggravations of chronic rheumatism. It does not destroy the rheumatic element in the blood.

Valerianate of sodium is declared by Granville to be very useful in weak and very sensitive patients. He even thinks its therapeutic value is decidedly greater than that of most of the other salts of sodium. It relieves the nervous trouble and hyperæsthesia of rheumatism and gout quite effectively, and he cannot help thinking that it also promotes the activity of the absorbents, thus tending to remove congestion, exudation, and even thickening and hardening about rheumatic joints. Usual dose, 1 to 5 grains.

It may be assumed that all the good that can be got out of sodium will be obtained by these preparations. Charcot always gives quinine, also, when he uses sodium or potassium in large and long-continued doses. Others prefer salicine as an anti-rheumatic tonic. Both prevent the excessive formation of uric acid. But the tartrate of potassium and iron is the best tonic against the anæmia and debility of chronic rheumatism. It is pleasanter and better than the muriated tincture.

But, as before said, the sodium salts only reach the liver and pancreas, the intestinal juices, the chyle and serum of the blood. They do not penetrate into the interior of the red blood-globules, nor into the parenchyma of the muscles and fibrous tissues, which the potassium salts do. The acetate of potassium, quickly supported by iron, is a most valuable remedy in subacute rheumatism, and especially in those forms which are liable to frequent acute exacerbations.

But citrate of potassium is a much more pleasant and less depressing remedy in very chronic cases.

There are, pathologically, two great varieties of chronic rheumatic joint-disease : 1, the fibrous ; 2, the dendritic. In the fibrous form the tendency of all the exudations is fibrogenous. The inflammatory products or thick-

enings, instead of remaining in the soft and gelatinous stage of fungoid granulation, become firm and tough. The new cells are converted into fibres, and these harden and contract ; even the inner surface of the synovial membrane is made hard. The normal dendritic growths of the villi are conspicuously absent, and in place of them are thick folds of fibrous tissue. The synovial membrane itself is infiltrated with fibrinous substance, composed entirely of fibre-cells, both fusiform and oval ; only a few round cells are to be seen.

The favorite remedy for this state is the muriate of ammonia, administered as freely as iodide of potassium is often given. If fears are entertained that it will prove too debilitating, it may be aided by aromatic spirits of ammonia, or with quinine, or Huxham's tincture of bark ; although Granville prefers the tincture of serpentaria, which he thinks has a specific effect. The muriated tincture of iron should not be forgotten.

Muriate of ammonia is a solvent and liquefacient remedy which tends to render all the secretions more abundant, while at the same time it reduces the plasticity of the blood, and destroys fibrin.

It acts upon the kidneys, and if long continued will cause emaciation, commencing first with absorption of fats and then of soft fibrin. It is used both internally and locally against fibrous thickening of the ligaments and tendons about rheumatic joints. Some go so far as to think it almost specific against all cirrhotic affections of the connective tissues. In chronic rheumatic synovitis it is said to break down all the exudations into a thin mucoid substance which is finally absorbed. It also has a powerful effect on the formation of urea : it is not only converted into urea, but helps to break down uric acid into urea, and aids in the excretion of both. It is also supposed to be really useful in so-called rheumatic neuralgias, when the fibrous sheaths of the nerves are involved. The dose is from 5 to 15 grains up to 150 grains a day.

Its great rival is corrosive sublimate, which may be given in doses of  $\frac{1}{4}$  to  $\frac{1}{8}$  or more of a grain, in Huxham's tincture of bark, or in the tincture of serpentaria.

The next great variety of chronic rheumatic arthritis, or synovitis, is the dendritic, in which the folds or fringes of the synovial membrane are greatly developed, so as to nearly resemble papillomata. For this sabina has been suggested, especially when it occurs in females at the menopause, or where there is decided

uterine derangement. Sabina once had a great repute, which was not undeserved, in chronic rheumatism and gout, for which it was employed both internally and locally to the affected joints.

Pulsatilla is a remedy which is supposed to act specifically upon almost all the mucous and synovial membranes, especially those of the small joints, and has a well-assured reputation in chronic rheumatism. It is most useful in subacute and chronic arthritic rheumatism when there is little or no fever; also in what is called rheumatic gout in females, with catarrhal and rheumatic disorders of menstruation.

But next to carbonate of sodium, Charcot prefers iodine to the muriate of ammonia and sabina; not iodide of potassium, but tincture of iodine, in doses steadily increased from 8 to 10 drops in twenty-four hours up to 30 to 60 drops. He gives it during meals in water slightly sweetened, or in a glass of Spanish wine, which he says is better. He continues it for several weeks, or even months, and says it never gives rise to symptoms of iodine-poisoning. Probably its effects are largely counteracted by the starch in the food. Granville also thinks iodine the most potent and suitable medicine to decompose urates in the blood, and says it relieves chronic rheumatic pains so promptly that he has rarely to use anodynes. But he always gives it combined with muriate of ammonia and chlorate of potassium, thus: Ammonii chloridi, ʒss; potassii chloratis, ʒii; tinct. iodinii, ʒii; glycerini, ʒss; aq., ad ʒxii. Dose, from a tea- to a table-spoonful two or three times a day. The taste of this mixture is more disagreeable than that of the tincture of iodine. One of the best prescriptions is that of Dr. Buckler, viz.: Iod. potass., gr. ii; iodid. ferri, gr. i; iodine, gr.  $\frac{1}{16}$ ; ext. conii mac., gr. i. Make one pill, to be taken three times a day. These pills are easily taken, and are said to be particularly efficacious in chronic articular rheumatism, even where there is an anæmic, scrofulous, or syphilitic taint. The so-called nodosity of the joints has been successfully treated with iodine.

Arsenic is the great rival of corrosive sublimate, iodine, and muriate of ammonia in chronic rheumatism of the larger joints. Occasionally it produces marked amelioration, but it often fails, and is said to be useless in the most inveterate cases. It generally aggravates at first.

Phosphorus is a more reliable remedy in arthritis deformans, and phosphate of ammo-

nia forms more soluble salts with uric acid than any preparation of sodium or lime. Uric acid and the urates disappear rapidly from the urine made after its use, and pains and swellings of the joints are relieved as rapidly as from any preparation of sodium or potassium. It is fully equal to the other alkalies, and preferable to most of them in delicate and feeble subjects. It maintains a highly alkaline condition of the blood, has a distinctly alkaline reaction itself, and renders the urine alkaline.

#### THE EXTRACT OF MALE FERN IN TÆNIA.

BEHRENS eulogizes the extract of male fern as by far the most efficient anthelmintic of the pharmacopœia, and in the *Deutsche Medicinal Zeitung* of January 7, 1886, reports its successful employment in fifty-two cases out of fifty-three treated. Fifty patients discharged the tapeworm after having taken a single dose of 5 grammes (75 grains); of the three remaining patients, two discharged the worm after one more dose of the drug. In two instances the heads of the worms were found. This rather remarkable success in the treatment of tapeworm Behrens believes to be attainable only if a certain methodical procedure is observed. The patient is, on the preceding day, not allowed to eat anything after dinner excepting a salted herring in the evening; for the thirst thus occasioned beer is allowed. On the following morning the patient takes the drug on an empty stomach, according to the following formula:

R Extr. filic., 5.0 (75 grs.);  
Gum. arab., 2.5 (37½ grs.);  
Aque dest., 5.0 (1½ fʒ);  
Syr. simpl., 15.0 (½ fʒ). M.  
S.—Take at once.

A quarter of an hour after, 1 fʒ of castor oil is taken.

This drug, which for its anthelmintic virtues has been known ever since the days of Pliny (who advocates its association with scammony), is well deserving of the author's praise.

In this connection it occurs to us that male fern, at the close of the last and the beginning of this century, formed an ingredient of several nostrums which enjoyed great repute for their vermifuge properties. It constituted the specific of Madame Nouffer, the widow of a Swiss military surgeon, who received eighteen thousand livres for the publication of its composition; later it was the Herrenschild remedy, and finally the specific of Matthieu, the Berlin apothecary, who sold it

to the Prussian government for the prize of a title and a pension. The medical college of Württemberg likewise bought and paid amply for this therapeutic secret. In all these cases drastic purgatives were given, either along with or after the preparation of fern.

In *tænia lata* (bothriocephalus), or unarmed *tænia*, the drug is far more efficient than in *tænia solium*, or armed *tænia*; hence we find the drug especially esteemed in Russia, France, and Switzerland, where the former variety prevails.

So much stress is laid upon systematic administration of male fern by all who have used it most extensively, that we shall describe several of the most approved methods, as cited by Stillé. Wawruch treated two hundred and six cases, nearly all of *tænia solium*, according to the following plan:

**Preparative Treatment.**—During four to five days a solution was given every day containing 20 grains of chloride of ammonia, the patient meanwhile taking no food but a thin broth at each meal.

**Expulsive Treatment.**—The night previously a simple injection was given. The following morning a bowl of thin soup without salt was eaten, followed in an hour by two ounces of castor oil in two doses. In the interval between these from  $\frac{1}{2}$  to 1 drachm of powdered male fern was given in two or three doses, and an enema of milk and oil. Some time after the last dose of fern a drastic purge of calomel and gamboge was given, and under its operation the *tænia* was generally discharged. This method occasioned a good deal of pain, and often vomiting, rendering the use of emollients and narcotics necessary.

The treatment of Albers, of Bonn, and which proved successful in a large number of cases, was almost exactly the same as that just described, except that the ethereal extract was the preparation of fern employed. Lambert preceded the administration of the fern by a diet of herring, onions, and similar crude articles. Trousseau's method, which, he states, was very successful, is as follows: First day, absolute milk diet; second day, 15 grains of the ethereal extract of male fern to be taken fasting, and repeated every half-hour until four doses are taken; third day, repetition of the extract as on the preceding day. After the last dose about 2 ounces of syrup of ether, and, in half an hour later, an emulsion containing 3 drops of croton oil.

Peschier used the oil (volatile extract), and in doses of from 8 to 25 drops, and cured one hundred and fifty cases in a short

time with it. Ebers, of Breslau, uses the alcoholic extract; Fouchon, of Neufchâtel, the oil in gelatin capsules. The simple powdered root, however, is probably the most eligible preparation.

#### NEW PURGATIVES.

A few years ago, Dr. Noel Gueneau de Mussy communicated to the Academy of Medicine Professor Rutherford's researches on different medicinal substances. M. DESNOS, according to the Paris correspondent of the *British Medical Journal* (January 2, 1886), has tested these experiments on four different bodies,—baptisin, sanguinarin, juglandin, and phytolaccin. They are all resinous extracts from American plants. They are brown-red powders, very hygrometric, and have a saltish taste. M. Desnos used them in the form of pills of from 5 to 10 centigrammes ( $\frac{3}{4}$  to  $1\frac{1}{2}$  gr.). Baptisin was administered to fourteen patients; sanguinarin to four; juglandin to thirteen; and phytolaccin to seventeen. The patients did not remain in bed all day, in order not to encourage constipation. The general dose was 30 centigrammes (about 4.6 grains) daily, administered in two separate doses. If more were given, a third dose was taken at eight o'clock at night. The patients generally had a stool the following day or night. In the case of patients habitually constipated, they gradually had regular motions. Baptisin in doses of 30 centigrammes was regular in its action, but frequently provoked colic. Sanguinarin, considered by Professor Rutherford as a never-failing cholagogue and purgative, was perfectly inert, though given in doses of 60 centigrammes. The action of juglandin, Dr. Desnos says, is the same as that of baptisin. In two patients, after it had been administered, the stools contained blood; one was convalescent after typhoid fever, and the other was rheumatic and dyspeptic. Phytolaccin, given in doses of 10 or 20 centigrammes, is regular in its action, and is not accompanied with colic.

#### TREATMENT OF ACUTE PROSTATITIS WITH VERY HOT WATER.

The singular though incontestable experience that in many inflammatory processes both heat and cold, though agents with diametrically opposed properties, possess often equal curative virtues, finds an apt illustration in the affections of the genital organs. In orchitis, for example, the ice-treatment enjoys

great repute. In prostatitis, however, better results have been obtained with hot water.

In the *Gazette Hebdomadaire* of January 1, 1886, Dr. RECLUS recommends compresses plunged in hot water and hot water enemata as the *par excellence* treatment of acute prostatitis. Reclus selects of the numerous cases thus treated the following as especially suitable to represent the advantages of this treatment :

1. A physician, æt. 31, called for treatment on account of a dysuria vesicalis appearing at the end of a blennorrhœa.

Examination of the parts revealed an enormous tumefaction of the prostatic gland, which was felt as a large tumor by the finger inserted in the rectum. There was intolerable pain before and after micturition. Compresses immersed in very hot water and rectal hot water injections were ordered, and almost instantaneously considerably diminished the pain, the vesical tenesmus, the tumefaction of the gland, and the other inflammatory symptoms. In three days a complete cure was effected by these simple appliances.

2. A professor, æt. 56, called for treatment on account of a prostatic trouble necessitating urination every couple of minutes, especially at night. As in the former case there was tenesmus of the bladder, and also of the rectum, great pain and enlargement of the prostatic gland, which could be found beating under the finger inserted into the rectum. Again the compresses were ordered to be applied to the perineum, and the injections to the rectum morning and night, and resulted in an immediate improvement and a complete cure within a few days. Both pain and the desire for frequent micturition never returned until a relapse occurred a year after, provoked by dietetic errors committed during a scientific congress, when the same means proved again successful.

3. A young man was treated for a neuroma on the mastoid portion of the temporal region, when, after removal of the tumor by the bistoury and the healing of the wound by first intention, suddenly, no doubt by some metastatic process, a prostatitis set in. Retention of the urine ensued, which rendered the use of the catheter necessary, which of course was very painful. The hot water treatment was ordered, and relieved in the course of four days both pain and tenesmus permanently.

This equally simple and energetic treatment cannot be too well recommended as an efficient means to allay the inflammatory process, no matter whether of a circumscribed or

a diffuse nature, and to prevent subsequent suppuration.

#### CHOREA SUCCESSFULLY TREATED WITH HYOSCYAMINE.

In a clinical lecture recently delivered in the Pennsylvania Hospital by Prof. DA COSTA (*Med. Times*, January 23, 1886), a patient was exhibited, suffering from what Dr. Da Costa described as the worst case of chorea that he had ever seen. The patient was a boy about 11 years old, pale and weakly, and described by his friends as having always been nervous.

Four weeks before the date when he was admitted (on the 14th of December) he had an attack of acute rheumatism, which involved all the larger joints of his body. The rheumatism lasted about three weeks, but as it declined choreic symptoms began to be manifested. His hands and arms were first affected, and afterwards his legs.

When admitted, he was actually unable to walk ; he was even unable to feed himself, and seemed in risk of starvation. He was wretchedly weak and emaciated. He could perform no co-ordinated movements with his arms or legs, and unless there was always somebody about to give him a drink of water and food he would have perished. This was not due to actual want of power in the muscles, but to the impossibility of performing any voluntary act requiring co-ordinated movements ; yet when food was placed in his mouth deglutition was readily accomplished. When admitted he could not speak, he could not articulate a word. He could not put out his tongue, although he could open his mouth and move his jaws, but he could not ask for food. His expression was that of an imbecile, and he was reduced to a mere shadow.

At first his arms and legs were constantly moving, both sides being equally affected. No power of grasp existed in his hands, though sensation did not seem impaired. He complained of pain when he was pinched. The patellar reflex was normal, and not exaggerated. No marked change in the electrical reactions was observed. His pupils were very much dilated ; his pulse was only 50 per minute, and rather weak ; there was a systolic mitral murmur heard at the apex. These involuntary muscular movements did not continue at night, when he was asleep. His urine had been examined, but neither albumen nor sugar was detected. His bowels tended to constipation.

The ordinary remedies for chorea act

slowly; arsenic, though one of the best of our therapeutic agents for this disorder, acts slowly; it takes time, and the loss of time here might be fatal. Dr. Da Costa then recalled a case of tremor which he had seen rapidly influenced by hyoscyamine, the active principle of *hyoscyamus niger*. He concluded to try it here. He ordered him to take  $\frac{1}{100}$  grain to begin with, a decided dose for a boy of his age; but, not finding any marked influence, he concluded that it would be advisable to increase the dose to  $\frac{1}{100}$  grain, given three times a day. Now the effect was admirable. From the first few days the boy began to improve, and at this time he had some dryness of the throat and wanted his mouth frequently moistened. He soon became brighter in his mind; he took more interest in what was going on; he moved voluntarily in bed, and tried to help himself to food. His voice also returned, and he left his bed and began walking around the ward. After this his recovery was rapid and uninterrupted. He has had no other treatment than the hyoscyamine, and he has now so much improved, though he is still somewhat pale, that he may be looked upon as having recovered. He can sit quietly; he has power over his hands, both in co-ordination and in grasp, although his grasp is still a little feeble. He walks and stands now without falling. His pupils are dilated, although not much.

The systolic apex-murmur persists: it is a chronic mitral regurgitant murmur. In every other respect the boy is nearly well.

Dr. Da Costa then referred to one or two points of clinical interest in connection with this case: first, some points which have nothing to do with the treatment; and, secondly, some which bear upon the treatment.

In the first place, this attack of chorea was clearly of rheumatic origin. It came on at the end of an attack of acute rheumatism. It is true that the boy was previously feeble and ill nourished, and that he was regarded as a nervous child; but the association of chorea with rheumatism is too close a one for us to regard it here as a mere coincidence. You can generally trace, in a case of chorea, a strong rheumatic element, either inherited or acquired. In this form, before the patient has left his bed or his attack of rheumatism is clearly over, the chorea is manifested: which makes the connection still closer. Now, it has been thought that there is an embolic process at work in the smaller blood-vessels of the motor centres in the brain and spinal cord; small vegetations which are formed

upon the valves are washed into the arteries supplying the motor tracts, especially the *corpora striata*, and the subsequent disturbances of nutrition give rise to the irregular, unco-ordinated muscular movements. This is a plausible and ingenious theory; yet it is hardly sufficient to account for all the features of the disease. There must be some want of stability of the motor centres, independent of the coarse lesions resulting from embolism, the evidence of the existence of which, moreover, is not complete, and which is certainly not constant.

In the case reported there was no voluntary control over the muscles, and at the same time the mind seemed to suffer: he was almost an idiot. When admitted, his temperature was  $98\frac{1}{4}^{\circ}$ : therefore the attack of rheumatism was over, and these symptoms were not due to a fresh outburst of the rheumatic affection. The want of power in these muscles must also be taken into consideration, as showing a close relation between chorea and paralysis.

Now, coming to the question of treatment, the influence of the hyoscyamine, which was suggested by analogy from the treatment of tremor, was here strikingly manifest. The dose was increased from  $\frac{1}{100}$  to  $\frac{1}{100}$  grain without any bad effects; but when he was taking this quantity he complained of some dryness of the throat, although it never was so severe as to require us to reduce the dose again. It was finally discontinued two days ago. Now he is perfectly steady and can control his movements; his tongue is clean and he has a good color; he is gaining flesh: indeed, he may be considered as well.

Did the hyoscyamine produce the striking effect, or did the rest in the hospital do it? That rest is good in all and can cure many cases of chorea, is admitted; but the improvement here was too sudden—coming on in three or four days—and too great to be attributed entirely to the good nursing and the food which he received since he was admitted. It is claimed that hyoscyamine is a valuable antispasmodic and exercises a remarkable control over muscular movements; also that with the control of the movements the condition of the muscles is improved and all the functions increased. Even the blood has improved; for, though he is still anæmic, he is not so much so as he was. Within a week after beginning the treatment he was out of bed and walking around, but not so well as at present.

What shall be given further? Will not the condition remain? Not necessarily; for all

the irregular muscular movements have ceased. He can take, however, for his anæmia, the elixir of the pyrophosphate of iron, a drachm three times a day, and stop the hyoscyamine as having accomplished its purpose.

#### ON FERMENTS IN THE URINE.

In the *Archiv für die gesammte Physiologie* (vol. xxx. No. 8, p. 35) we find a publication of DR. GEHRIG, which informs us of the results of his numerous experimental observations on the constituents of urine.

We abstract the following conclusions :

1. Normal human urine contains nearly always pepsine, trypsin, and a diastatic ferment in varying proportions.

2. The influence of ingested food on the relative and absolute quantities of excreted ferments is shown by diminution of pepsine and trypsin, and an increase of the diastatic ferment. The former reach a minimum in three to four hours after a meal, the latter a maximum.

3. In the normal urine of dogs all three ferments are found in appreciable quantities, the diastatic ferment, though, in the smallest proportion.

4. The relative and absolute quantities of all three ferments show a minimum several hours after feeding.

5. The normal urine of rabbits shows, after ample nutrition, always small quantities of trypsin and diastatic ferment, but only traces of pepsine.

6. After fasting for not too long a period the urine of men, rabbits, and dogs shows all three ferments in ample relative and absolute proportions.

#### MASSAGE IN THE TREATMENT OF INFANTILE PARALYSIS.

The advantages of this method of treatment lately formed part of a lecture by DR. MURRELL (*Med. Press and Circular*, December 23, 1885) on the above disease, and as it includes some important modifications in the ordinary manner of conducting the operation, it may be worth while to draw attention to it. After treatment during the acute stage by means of aconite, followed later on by physostigma and phosphorus, recourse is advised to a carefully graduated system of massage, commencing with simple *effleurage*, or surface rubbing, followed by the friction, which is a more energetic application. As the case proceeds, kneading of the affected limbs or muscles is

resorted to, and this is succeeded by or combined with systematic *tapotement*, which is a form of percussion. This plan of treatment, conscientiously carried out, has, when the case has not been too long delayed, been followed by excellent results, but it should only be done by the advice and under the care of the medical attendant, as indiscriminate massage is likely to be futile, and may be injurious. The operation should be conducted with dry hands on a dry skin, and all oily or other unguents studiously avoided.

#### INOCULATION OF TUBERCULAR MATTER IN ANIMALS.

DR. COLIN, of Alfort, has been engaged a number of years in experiments of inoculating animals with tubercular matter. In a note communicated to the *Gazette Hebdomadaire* of January 1, 1886, he states that the entrance of the tubercular matter into the absorbent apparatus determines both the ensuing lymphatic affection and the subsequent visceral implication. The former is not generalized, but always limited to the portion of the body in which the matter was originally introduced. The circulatory channel was in every instance found to be the way of the progressive tubercularization of the animal.

#### VIOLINIST'S CRAMP TREATED SUCCESSFULLY BY ELECTRICITY.

DR. ADOLPHE WAHLTUCH, Honorary Physician to the Hulme Dispensary, Manchester, reports in the *British Med. Journal* for January 2, 1886, the case of a young woman, aged 19, who consulted him in July, 1885. She had been learning to play on the violin since she was 12 years old ; and during the last twelve months, whilst practising a short time, she felt obliged to stop on account of a painful cramp in the upper left arm and right wrist. On examination he noticed that she could not raise her left arm as high as she did the right one. In getting the violin in the proper position, the cramp and pain manifested themselves in the left deltoid, biceps, and pectoralis muscles ; the right hand holding the bow soon felt unable to do so, owing to a weakness in the wrist. In every other respect she enjoyed very good health. The treatment consisted in applying, three times a week, a continuous current of galvanism to each of the affected muscles, separately, for five to ten minutes at a time, using from five to fifteen Leclanché cells. To the right wrist he at

first used the faradic, and, later on, the continuous current. In all, nine applications were made within three weeks, when all unpleasant symptoms ceased. She was seen three months later, when she stated that she could practise then for several hours daily without experiencing any inconvenience whatever.

In looking up medical literature, Dr. Wahl-tuch was unable to meet with any record of cases of "violinist's cramp." This affection, though rare, yet belongs to a group of spasmodic diseases, among which the most familiar is that of "writer's cramp." Benedikt mentions a case of "knitter's cramp," and "tailor's cramp;" Watteville, "telegrapher's cramp;" Dupuytren, "coachman's cramp;" Henoch, "nailsmith's cramp;" Basedow, "milkmaid's cramp;" Clemens, "shoemaker's cramp;" Kunze, "typesetter's cramp;" and various authors, "pianist's," "painter's," "seamstresses," and "writer's cramps." No doubt, violinist's cramp is an analogous condition, having the same general characteristic,—namely, the recurrence of spasm or pain in a special group of muscles, when called upon to execute a series of combined special movements. It is a disturbance of co-ordination, caused by overexertion. The treatment generally consists in allowing temporary rest to the muscles implicated, and also rational and harmonious local gymnastics. But the most effectual results are obtained by the use of electricity. In the case mentioned above, violin practice was not stopped altogether during the treatment; the patient was allowed to practise for a very short time every day, and advised to play tennis, to write, to paint, and generally to use her hands in a variety of occupations.

#### ON SCANTY NITROGENOUS DIET IN DIABETES.

In a note of BOUCHERON appearing in the *Comptes Rendus* of December 14, 1885, we find some valuable dietetic hints for diabetic patients.

Boucheron refers to the fact that numerous diabetic subjects have also a gouty diathesis, and habitually indulge in food rich in albuminoids and in fermented beverages. The experiments of numerous observers prove that an exclusive albuminoid regimen leads to glycosury in the liver, and to a diffused glycosury in the entire organism. In dogs fed for some months exclusively on meat, glycogen is elaborated at expense of the in-

gested albuminoids. Albumen hence produces sugar just as well as the hydrocarbons, only the latter fact is better known.

In diabetes mellitus the sugar produced by albuminoids is equally, if not more, deserving of our consideration than the sugar derived from the hydrocarbons. Albuminous diet consequently increases the sugar-production in diabetic patients, and is to be cut short as much as possible, not only with the view to reduce and avoid glycosury, but also to diminish the nitrogenous products (urea, uric acid, and ptomaines). Abstinence of hydrocarbons alone will consequently not be the only indication in diabetes.

#### THE EXPLORATION OF THE UTERINE CAVITY IN CASES OF METRORRHAGIA.

At the meeting of the British Gynæcological Society, held on December 9, 1885 (*British Med. Journal*, January 16, 1886), DR. EDIS read a paper on this subject. The author desired to draw attention to the urgent necessity of this proceeding when dealing with cases of severe persistent or recurrent uterine hemorrhage. The subject was one of great interest, and often one of great anxiety to the practitioner. There was a tendency to treat metrorrhagia as if it were a special disease, in place of regarding it merely as a symptom of many and various conditions. A correct diagnosis was the first and most important element of successful treatment, which otherwise was mere guess-work. Speaking generally, there was almost invariably some local cause when the hemorrhage was really severe. Cardiac, hepatic, or renal disease might be present as a complication, or independently, and should always be taken into consideration. Uterine hemorrhage might be aggravated by the injudicious use of alcoholic stimulants; more especially was this the case about the time of the menopause. The author had repeatedly witnessed cases where the mere abstention from alcohol had been sufficient to arrest a profuse hemorrhage, which had been going on for months, and threatened even the patient's life. In attempting to form a rational diagnosis, it was of great importance to get a careful and exact history of the details of the case. Before proceeding to local investigation, the heart, lungs, liver, and other organs should be carefully examined, and inquiry made into the habits of the patient. A careful pelvic exploration should follow. Then if, after consideration of all the facts of the case, the

presumptions were, everything else being excluded, that there was some intra-uterine complication, the practitioner was not justified in allowing the patient to go on bleeding indefinitely without giving her the benefit of further assistance. The author, in general, effected dilatation by dividing the cervix with the metrotome or scissors, either alone, or in conjunction with the employment of tents or other dilators. It was advisable, after operation, to irrigate with some appropriate antiseptic lotion, morning and evening, for a few days. In cases of persistent hemorrhage, due to retention of the placenta, following a miscarriage, the cervix generally remained sufficiently patulous, or was so readily dilatable, that no difficulty was experienced. Where, however, only a small portion of the placenta had been retained, and the case allowed to go on for several successive weeks or even months, the cervix might be found so contracted as to necessitate the introduction of laminaria-tents overnight. In such cases, incision should never be resorted to, this method being reserved exclusively for cases of small fibroid or fibroid polypi in the interior of the uterus. The author related several interesting cases to exemplify his meaning, and to show that, until the cavity of the uterus had been explored, a correct opinion could not be formed as to what method of treatment should be adopted. He would lay stress upon the importance of dilating the cervix and exploring the interior of the uterus in all cases where hemorrhage from the organ persisted unnaturally, and where the ordinary medicinal agents failed in affording relief, and there was no evidence of any condition external to the uterus sufficient to explain the persistence of hemorrhage.

DR. AVELING had observed that, in cases requiring dilatation where something existed in the uterus capable of being removed, the cervical canal was either dilated or dilatable; this peculiarity had been noticed by Harvey. In these cases, he preferred to use his own dilators. Where the os was rigid and contracted, a more gradual method was better.

DR. ROUTH believed that Dr. Edis's paper was eminently practical, but he took exception to one or two points. As to rapid dilatation of the uterus, it did not always succeed when the uterus was rigid; and after all it was not a rapid, but a long and tedious process, requiring an anæsthetic. He preferred the sea-tangle-tents used with proper precautions, and always collected and prepared his own. In regard to those cases of metrorrha-

gia in which nothing could be found after exploration, it should be remembered that an ulcerated or excoriated condition of the mucous membrane need not be restricted to the os or external portion of the cervix, but might extend up the uterine cavity. It was quite in keeping to suppose that a congested state of the liver would have the same effect on the uterine mucous membrane as was the case in piles, causing them to bleed and enlarge. The last objection he could take was to the incision of the cervix. The danger to the patient from septic poisoning was greatly increased by such a measure.

DR. BARNES thought no law in therapeutics more clear than that which dictated direct examination of an organ at fault if it could be effected. The endeavor to do so was made, in the case of other organs, by percussion and auscultation. The uterus offered the incontestable advantage of being directly accessible. A narrow condition of the os externum was a frequent factor in cases of hemorrhage. Great benefit was often derived from simply enlarging this opening by a strictly limited incision. The immediate effect was to relieve local engorgement. It also afforded a ready escape for imprisoned blood-clots and mucus, and gave free access for exploration and the application of topical remedies. It was also useful in many cases of intra-uterine polypus and fibro-myoma of the body of the uterus.

DR. THOMAS SAVAGE found Hegar's dilators to be very unsatisfactory. Laminaria-tents were much more efficient, but were sometimes followed by disastrous consequences. In several cases in which he had suspected a portion of the ovum to be left behind, he had thoroughly swabbed out the uterine cavity with pure carbolic acid, and found that such a course would often prove sufficient for cure.

DR. BANTOCK was compelled to dissent from Dr. Edis on one or two minor matters. He did not approve of incising the internal os after partial dilatation for the purpose of removing a small fibroid tumor, because it would be impossible to control the subsequent extension of the laceration of the divided tissues consequent on the forcible extraction of such a hard body as a fibroid tumor. He had met with cases exactly corresponding to those narrated by Dr. Edis, and it was quite easy for him to support his views. He thought it was a mistake to mix glycerin with iodine or carbolic acid when the full effects of either remedy were desired, for in both instances the caustic effect was in this way reduced to a

minimum, if not wholly removed. Especially was this the case with carbolic acid. He was not prepared to assent to the doctrine that a cervix which was the subject of even extensive disease of a non-malignant character, but the result of chronic catarrh, etc., should not be subjected to dilatation. These were just the cases in which he obtained the most satisfactory results from dilatation and the subsequent daily introduction of a strip of lint saturated with glycerin for ten to fourteen days.

MR. LAWSON TAIT considered the use of sponge-tents to be, of all the methods of dilatation, the most dangerous, and had long since given them up. Hegar's dilators he considered extremely risky, and their employment was as exhausting for the operator as for the patient.

#### COCAINE IN LARYNX, PHARYNX, AND NOSE.

DR. DESSAR epitomizes his experience with cocaine in the larynx, pharynx, and nose in the following aphorisms (*Deutsche Medicinal Zeitung*, January 7, 1886):

1. Cocaine reduces the sensibility of those parts, even in existence of hyperæsthesia, to such an extent that the laryngoscope and rhinoscope can be employed with ease.
2. Reduction of pain, especially in operations.
3. Removal of pain and difficulty in swallowing in presence of a stenosis depending upon tumors in phthisis, syphilis, perichondritis, and tonsillitis.
4. Ischæmia in case of strongly injected mucous membranes.
5. Diminution of profuse hemorrhages.
6. Insurance of diagnosis in reflex neuroses of the nose. For purposes of examination a five per cent. solution is sufficient; for those of cauterization of the pharynx, nose, and for the removal of deglutition-difficulties, a ten per cent. solution, and for laryngeal operations a twenty per cent. solution, are required.

#### THE EFFECTS OF A HEAVY DOSE OF SALICYLATE OF SODIUM.

We have a number of times referred to the untoward effects produced by salicylate of sodium when given in large doses, and DR. JULIAN J. CHISHOLM, in the *Maryland Med. Journ.*, January 30, 1886, is able to confirm the experience of others in this respect. He states that he has been employing the salicyl-

ate of sodium for the treatment and relief of painful attacks of neuritis, whether specific or rheumatic in nature, and he has found that it will subdue pain and remove congestions of the eye-tissues more rapidly than any other remedy he has tried. In a dose of from 25 to 30 grains, given every four hours, the beneficial effects are often magical. Patients who could not sleep on account of pain in the eye, notwithstanding leeching and the local use of atropine and the administration of iodide of potassium and mercury with opium, have obtained complete relief before a half-dozen doses of sodium powders have been taken. The eye-pain and eye-congestions vanish, and convalescence seems to be very well established after a few doses of the salicylate. When, however, the remedy is pushed for any length of time, it sometimes produces headache very similar to that produced by quinine, possibly even in a more severe degree. Recently, however, through the mistake of a druggist for reading 4 drachms as 4 ounces, a patient received in one powder 192 grains of the salt instead of 24 grains which were ordered. Very shortly after taking the first powder his head felt full and his ears commenced to buzz. He became weak, was nauseated, and had to go to bed. At six o'clock, four hours after taking the dose, diarrhœa set in, and one hour later he vomited. The night was passed in such miserable wretchedness that a second powder was not administered. The next day the brother of the patient came to explain to Dr. Chisholm the effects which the powder had produced, and brought him one of them for examination. He reported the patient now relieved of nausea and diarrhœa, but too weak to get out of bed. The eye no longer gave him pain. He did not know at what time relief came, as his other more pressing annoyances were all-absorbing. He got out and to my office in three days after the dose was taken. All pain and injection of the eye had disappeared. The cloudy vision had nearly gone, and no further eye treatment seemed necessary. The case is instructive in many ways, and offers comfort to many practitioners who prescribe  $\text{ḡi}$  doses of the salicylate of sodium with hesitation, fearing bad effects from what they believe to be so large a dose. This dose of 192 grains, dissolved in a half-tumbler of water, had caused diarrhœa before vomiting, which did not take place until five hours after the medicine had been administered. We might, therefore, fairly believe that after five hours not much of the drug remained in the stomach to be ejected, and that

the effects produced represent the degree of depression which so large a dose can occasion. The symptoms could not have been alarming, as it was not thought necessary to call for advice till the next day, when only a general debility remained.

#### ON SUGAR IN THE URINE AFTER FEEDING WITH CANE-SUGAR.

SEEGEN publishes in *Pflüger's Archiv* (xxxvii. p. 342) the following results of his experiments on dogs. Being fed with cane-sugar, the animals excreted all sugar with the urine as represented by the following table :

	SUGAR.		
	Ingested. Grammes.	Excreted. Grammes.	Per cent.
Dog I.	520	15.2	3.0
" II.	560	22.0	4.0
" III.	480	7.0	1.9

#### THE TREATMENT OF PROFUSE HÆMOP-TYSIS.

In discussing the treatment of hæmoptysis, of course only the cases in which the hæmorrhage is profuse need to be considered, for slight hæmoptysis requires no definite treatment. In the treatment of the serious form the general methods employed must be the same as that for profuse hæmorrhage from other parts of the body ; and although containing no new points, the paper recently read by DR. SAMUEL WEST before the Medical Society of London (*Brit. Med. Journ.*, January 16, 1886) contains the most successful methods, brought together in such a succinct way that it is worthy of being laid before our readers. Dr. West shows that rest, absolute of the body as a whole and of the diseased part so far as possible, is the main essential principle ; and with this object in view the patient should be kept in a recumbent position, speaking prohibited, cough checked, and excitement avoided, or, if present, controlled by drugs. These indications are best met by the use of opium, which Dr. West regards as indispensable in most cases of hæmoptysis. Of the so-called hæmostatic remedies two groups may be formed,—the topical astringents and the vascular constrictants. Chief among the former are the perchloride of iron, alum, gallic and tannic acids, and acetate of lead ; but, powerfully as these remedies act when applied to the bleeding surface, it is difficult to see how they can produce the same local effect when administered by the mouth, for it is hard to comprehend

how a few minims of dilute solution introduced into the stomach can produce an effect which the undiluted solution can effect only when applied directly to the bleeding surface ; consequently, if they act at all, it must be by producing vascular constriction. Of the groups of remedies which produce vascular contraction, digitalis and ergot are the most prominent examples. Both of these drugs produce contraction of the peripheral arteries, and if hæmoptysis were due to capillary oozing they might possibly arrest the hæmorrhage ; but we know that hæmoptysis is not due to capillary oozing, but to lesions of fairly large vessels. Hence these remedies, instead of being useful, may be even dangerous, and increase the hæmorrhage. Hæmoptysis always tends to stop itself, from the fact that the blood-pressure is reduced from the loss of blood, and the greater the reduction the greater is the tendency to form a clot. This fact has long been recognized, and therefore one of the early standard methods of treatment of hæmoptysis was to produce hæmorrhage from other parts by free blood-letting ; and although blood-letting is now believed to be indicated in but very few cases, an attempt may be made to reach this end, not by removing the blood from the body, but by detaining it in some part of the body distant from the seat of the hæmorrhage. This may be, to a certain extent, accomplished by extensive dry cupping, or by dilating some of the vast vascular systems of the body, and making them act as temporary reservoirs for the blood. This might possibly be accomplished by producing purgation, or the cutaneous system might possibly be dilated through pilocarpine, or even nitrite of amyl ; however, the possible objection to the use of these drugs is they dilate the vessels of the lungs as well. Then, again, the blood-pressure may be influenced through the heart, as by use of cardiac depressants, of which antimony is the most reliable ; while, lastly, diet is of the very greatest importance. The principle of absolute rest and restricted diet should be applied in all cases of hæmorrhage. It is thus seen that without giving a long list of drugs, or discussing in detail the various methods of treatment of hæmoptysis, Dr. West indicates the conditions which have to be fulfilled and the essential principles which should guide our choice of remedies. Our treatment of hæmoptysis is as yet extremely unsatisfactory, and perhaps the following out of some of the lines of treatment suggested above may lead to valuable results.

**EXPERIMENTS WITH NUMEROUS DRUGS  
ON THE BACILLUS TUBERCULOSIS.**

If Koch's bacillus tuberculosis is actually the cause or infectious agent of tuberculosis, the labors of SORMANI and BOGNATELLI to ascertain the effect of various drugs on the microbe are in the right direction to possibly advance the therapeutic aspects of this affection. We abstract from their papers, "*Ricerche Sperimentali sui Neutralizzanti del Bacillo Tuberculea Scopo Profilattico*" and "*Ulteriori Ricerche sui Neutr. del Bac. Tuberc.*," Milano, 1885, simply their general conclusions.

Both authors tested a number of chemicals, especially such which could be therapeutically considered as to their influence upon the vitality of bacillus tuberculosis. One c.c. (16 gtt.) of sputum, in which the presence of a large number of bacilli was previously ascertained, was, under the ordinary precautions, mixed with a certain quantity of the drug to be tested, the mixture preserved at a temperature of 35° to 40° (C.) one to two hours, then mixed again, and by means of a disinfected syringe injected in the abdominal cavity of guinea-pigs. These animals, unless they died sooner, were killed after two to three months and examined for bacilli. A large number of drugs showed no or a very slight pertinent action. An appreciable antibacillar effect was obtained from the following drugs in an ascending order: lactic acid, camphor, bromide of ethyl, naphthol, turpentine, chloride of palladium, creasote, carbolic acid, and corrosive sublimate. The following drugs showed likewise some antibacillar virtues: benzine, toluol, oil of caraway, essence of cloves, guajak, chinolin, menthol, and creasote.

**ACUTE PROSTATITIS WITH DISCHARGE  
OF HYALINE CASTS.**

At a meeting of the Clinical Society of London, held January 8, 1886, SIR ANDREW CLARK read an account of a case of acute prostatitis which was accompanied by a discharge of hyaline cylinders resembling renal tube-casts (*Medical Press*, January 13, 1886). A medical man in average health was suddenly seized with pains in the limbs and loins, there was frequent desire to pass urine, and scalding when it passed, with pain at the anterior extremity of the urethra. The urine rapidly became bloody, accompanied by much dysuria and tenesmus. No evidence of disease other than that in connection with the urinary organs could be discovered. The

urine, examined by the naked eye immediately after its discharge, exhibited numerous minute thread-like fragments. Under the microscope they were seen to consist of hyaline cylinders, in several instances covered by patches of leucocytes. On standing, the urine deposited a mixed sediment in a thin even layer. The specific gravity of the urine was 1022, its reaction acid, and it was slightly albuminous. The sediment contained uric acid crystals, oxalate of lime, blood-disks, patches of epithelium from the bladder, leucocytes, flask-shaped hyaline bodies, and hyaline cylinders. The crystalline constituents appeared to have been formed in the urine subsequent to its discharge. On examination per rectum, the prostate was found much enlarged, and very tender to the touch. The patient was soon after seen by Sir James Paget, and the symptoms of the local disorder had become aggravated. By degrees, the uric acid, oxalate of lime, and larger hyaline casts disappeared from the urine. A small quantity of albumen, however, remained, and on standing, the sediment showed much mucus and small hyaline cylinders with flask-shaped hyaline bodies. After eight days' illness, at the close of micturition there was discharged a pultaceous mass of mixed mucus and phosphates, and this discharge continued for nearly a fortnight in steadily diminishing quantities. The patient entirely recovered after being ill a little more than a month. During the last six years the only symptoms that have arisen have been such as he himself ascribes to imperfectly developed gout. The important point in these cases is the discharge through the urine of hyaline moulds of the vesicles, and smaller ducts of the prostate. Before finding the connection between the cylinders and the flask-shaped bodies, Dr. Clark was inclined to think the latter originated in the kidney, but further study of the case, and two others similar to it, and examination of the prostate after death, have convinced him of their prostatic origin. These cases with prostate casts in the urine may be only curiosities of medical experience, but since in none of the standard works on urinary affections, in no monographs dealing with diseases of the prostate can any reference be found to the discharge of hyaline cylinders in prostatitis, and without careful examination they might very easily be mistaken for cylinders originating in the kidney, the case is certainly of sufficient importance to bring it before the notice of the profession.

MR. BRYANT said it was pleasing to see a physician taking an interest in a case which

we usually considered as belonging rather to surgical diseases. We could recognize by the eye these bodies in prostatitis, but there was no microscopical evidence that they were casts of the prostatic ducts themselves. He would like to ask Sir Andrew Clark in what way we could be saved from the fallacy of mistaking these casts for renal casts.

DR. GREENFIELD, of Edinburgh, said it was his misfortune to have arrived too late to hear the whole of Sir Andrew Clark's paper, and he felt he must apologize for venturing to speak on the subject, but he thought he could raise some parallel cases. He had seen lately four cases with concretions exactly like those found in prostatitis, concretions which resembled corpora amylacea. The cases consisted of two girls, a young woman, and a boy æt. 7. In the boy these bodies appeared in the urine intermittently. In the females, they also appeared from time to time. In one case he had found after death a large number of these bodies in the kidney. They varied much in character; some were small and hyaline with fine lamination, some gave a deep stain with carmine, some with magenta, and some with iodine. The subject was a comparatively new one to him. He had not come across these cases often. He merely brought these cases forward as presenting a condition worthy of being considered side by side with prostatic concretions in the urine. He had found these bodies recently in two cases of cancer. He thought they might occur widely in many pathological conditions.

DR. GLOVER asked whether the patient had a well-defined attack of gout?

SIR ANDREW CLARK in reply said no, but the patient considered himself gouty. He presented symptoms of a varying kind which he (Sir Andrew Clark) thought could only be assigned to the circulation of acid in the blood. The question which his paper suggested was by what means can we distinguish hyaline casts or cylinders as coming from the prostate gland or from the kidney. He thought the case upon the first examination to be one of acute nephritis. The cylinders looked exactly like those occurring in acute renal congestion, but upon a second investigation he found some little flask-like bodies attached to the hyaline cylinders. The prostate was troubled. The urine was healthy, plus a little albumen. He felt it was more a case of prostatic disease. He had not published the case at the time (some years ago), as he was anxious to discover if any other symptoms showed themselves. Nothing had, however, arisen. In

other cases he had seen symptoms of a similar character. To Mr. Bryant's question his answer was, you could not discover the nature of the cylinders from their aspect, you could not even be sure if the prostate was their seat of origin unless you found these hyaline moulds associated with the hyaline cylinders. In women's urine he had always found numerous starch-like bodies. Whether it be that they use violet powder or some such substance, but somehow or other the starch-like bodies were always there.

#### *THE ELIMINATION OF BISMUTH.*

M. HANS MEYER has poisoned mammals and birds by injecting under the skin or into a vein large quantities of the salts of bismuth. At the necropsy the large intestine and its surroundings were seen to be of an intense black color; often there existed also large tracts of necrosis of the mucous membrane of the large intestine, whilst the stomach and small intestine preserved their normal appearances. Chemical analysis of the wall of the intestine and of the contents has demonstrated that the digestive tube all along serves as an excretory surface for bismuth, but that this elimination takes place much more actively at the surface of the large intestine, and that the metal is excreted in the form of a sulphide. By previously making the animals ingest preparations of sulphur, the elimination of bismuth was augmented in the stomach and small intestine, and the wall of the stomach became pigmented of a deep black color. The author concludes from these facts that the presence of sulphuretted hydrogen favors the elimination of the bismuth by precipitating the metal from the capillary circulation of the intestine in the form of the insoluble sulphide, which plays the part of a foreign body. If this precipitation does not take place, the metal re-enters the circulation, and is eliminated largely by the kidneys. As the necrotic tracts and ulcerations are met with almost exclusively in those portions of the digestive tract where the pigmentation obtains its greatest intensity, the conclusion is naturally arrived at that the precipitation of the bismuth in the thickness of the intestinal mucous membrane has caused the necrosis and ulceration by the precipitate blocking the capillaries and vessels of the parts concerned. Further, if the animals are made to ingest simultaneously salts of bismuth and substances that disengage sulphuretted hydrogen, neither necrosis, ulceration, nor pig-

mentation of the intestine occur, evidently because the bismuth and sulphuretted hydrogen in combining mutually neutralize each other. According to Hans Meyer, also, it is probable that in mercurial poisoning the inflammation and necrosis of the gastro-intestinal mucous membrane depend, in a similar manner, on putrid fermentations which disengage sulphuretted hydrogen. It is well known that the prevention of mercurial stomatitis by the use of dentifrices and antiseptic lotions is due to their property of preventing the processes on which the development of sulphuretted hydrogen is dependent.—*London Lancet*, January 2, 1886.

#### THE USES AND DANGERS OF THE OIL OF SASSAFRAS.

In the *Virginia Med. Monthly* for January, 1886, DR. THOMAS J. MILLER publishes an article on the oil of sassafras, which he recommends highly in the treatment of neuralgia. His method is to saturate a piece of flannel with the oil of sassafras, and rub the affected part briskly until the skin is reddened by the friction, and to take a teaspoonful in several tablespoonfuls of water. It also appears to possess decidedly intoxicating effects.

In this connection a paper read before the Chicago Gynecological Society by DR. JOHN BARTLETT (*Chicago Med. Journ. and Exam.*, December, 1885) is of interest. He quotes a number of authorities to show that sassafras is not the innocent agent that it is supposed to be, but that in reality it has violent toxic properties. This statement is based largely upon a paper of Dr. Charles L. Hill, which we have already referred to in the August number of the *GAZETTE*, p. 554. Dr. Bartlett further shows that, in addition to its general toxic properties, it seems to have decided power in producing abortion, and he refers to two cases in which this result followed the internal use of sassafras in the form of a tea. According to Dr. Bartlett, sassafras is a narcotic and sudorific; it has the power of inducing tetanic and clonic spasms, followed by paralysis, and produces uterine contractions.

#### ON A NEW FORM OF CITRINE OINTMENT.

On referring to the new edition of the British Pharmacopœia, just published, it will be seen that the unguentum hydrargyri nitratil dilutum is ordered to be prepared with paraffinum molle, soft paraffin, the synonymes

being petrolatum (its designation in the Pharmacopœia of the United States), petroleine, and unguentum paraffini. It is described as a semi-solid mixture, containing some of the softer or more fluid members of the paraffin series of hydrocarbons, usually obtained by purifying the least volatile portions of petroleum.

These characters do not, however, give us any standard of purity; and, beyond describing the melting-point, we are left in ignorance as to what form of petroleum-jelly we should employ. The material purpose suggested by this innovation in the preparation of this particular ointment is clearly to obviate the destructive effects of decomposition, with its resulting rancidity, which obtained to a very objectionable extent in the old form of the dilute citrine ointment.

This hitherto has been prepared with lard, and sometimes even with an animal oil, such as neat's-foot or trotter oil; sometimes with fish oil, such as cod-liver oil,—the latter serving to keep the ointment better and longer than the former, and being considered by some as more efficacious as a remedial agent. It has also been prepared with fresh butter; this also keeping fairly well.

As soon, however, as the Americans discovered the petroleum-jelly, and it was introduced into Great Britain, it was hoped that it would supersede all these articles in the preparation and dilution of citrine ointment in particular; but utter disappointment was the inevitable result of the trial and the experiment, as rapid oxidation, decomposition, and rancidity set in, just as in the old form prepared with lard, etc.

The cause of this decomposition MR. BLERNERHASSETT ATTHILL (*Brit. Med. Journ.*, Jan. 23, 1886) believes to be dependent upon the manufacture of petroleum-jelly through some acid process and by the addition of possibly some resinous matter or honey with the pretence of giving emolliency and consistency. Mr. Atthill believes the petroleum product which is known under the name of "geoline" to be the best vehicle in the preparation of citrine and oxide of zinc ointment. He states that he has found it to be in every way a perfectly efficacious and stable medium in all ointments, and especially in preserving the citrine form. It blends admirably with nitrate of mercury ointment, and it makes a stable oxide ointment, which keeps for an indefinite length of time. The dilute citrine ointment made with geoline keeps absolutely pure. It is of a firm consistency, pleasant in

its use, having a nice jelly-like appearance, and about 75 per cent. is saved over lard.

The melting-point at which geoline liquefies is stated to be 105° F., so that its consistency in ordinary use is its great advantage over other fluid preparations.

#### *TREATMENT OF SPONDYLITIS WITH THE PLASTER-OF-PARIS JACKET.*

PETERSON obtained very satisfactory results with the plaster-of-Paris jacket in spondylitis; as published in the *Archiv für Klinische Chirurgie* (xxxii. p. 182), of twenty-six cases of spondylitis treated with the plaster jacket and Barwell's sling, eighteen were cured, four remained under treatment, two died, one was not cured, and one had an unknown issue. The duration of the treatment was from three months to three years, and the number of jackets needed was on an average six. In most instances the patients felt contented with a comparative slight improvement in their condition.

#### *ALBUMINATE OF CORROSIVE SUBLIMATE AS A SURGICAL DRESSING.*

Attention has been directed to this powerful germicide by a most interesting article on the value of an albuminate of corrosive sublimate by Prof. Sir Joseph Lister in the number of the *Lancet* for October 25, 1884. In it the professor, after numerous experiments, recommends a one per cent. solution as the one combining the two advantages of being efficacious and unirritating to the tissues. Writing from London, and having in view the large requirements of a general hospital, he recommends the using of the serum from horse's blood as the menstruum for the corrosive sublimate. The wants of the general practitioner would necessarily be different: namely, what he would require would be some ordinary vehicle that any chemist could procure without difficulty, and of whose purity there could be but little doubt. It occurred to MR. W. L. CLELAND (*Australasian Medical Gazette*, December, 1885) that the simplest and most commonplace article would be the albumen ovi of the pharmacopœia. As a rule an ordinary egg will furnish one ounce of albumen in the form of white of egg; and one ounce of the albuminate would, in ordinary circumstances, be ample to prescribe at one time for any ordinary surgical case. Since that time he has put the idea into practice, and has been so pleased with the result that he has thought it worth while to

draw special attention to Prof. Lister's important discovery. Ordinarily the sample is of a creamy consistence. This, of course, would render it unsuitable for injecting into cavities, and therefore his experience of it is limited to its application to superficial wounds and ulcerations of the surface. The method of using it that he has found most convenient is to paint the surface of the wound or ulcer with the albuminate, place a piece of protective over, and then a pad of some antiseptic wool to catch and absorb any discharge. Dressed in this manner it will be unnecessary to disturb the parts for a period varying from three or four days to a week or ten days. Mr. Cleland publishes notes of three or four illustrative cases:

(1) J. B., æt. 50, contused and lacerated wound, three inches by two inches, of the back of the hand, inflicted by a pick, exposing the extensor tendon of the middle finger, and abrading it. Dressed at first every third day, and then weekly, and subsequently fortnightly. Completely healed without any bad symptoms.

(2) H. W., æt. 45, malignant ulceration of mamma, sinus leading to sacrum and another in connection with the femur. Syphilitic history suspected. Discharge from all the ulcerated surfaces extremely offensive. At first the wounds and cavities were syringed twice daily with carbolic lotion (one in forty), and dressed with carbolic oil and salicylic wool. The odor of the ulcerations was very offensive to the patient himself and to his fellows. The albuminate was tried, in conjunction with the carbolic syringing, at first daily and subsequently every third day. The offensiveness disappeared and the ulcerations even assumed a more quiescent appearance, becoming dried up or mummified to a great extent. The patient subsequently left the asylum.

(3) C. H., æt. 55, chronic ulcers of leg and dorsum of foot, edges indurated, surfaces unhealthy looking. The application of the albuminate speedily removed all unpleasant odor, and the ulcers took on a healing action and progressed to a favorable termination. This case was the more striking as the patient was emaciated to a degree, although she consumed large quantities of food with avidity.

(4) A. S., æt. 50, in the last stage of emaciation; the extremities constantly cold and blue; paralysis of the vaso-motor nerves controlling the capillaries of the face, causing a deep carmine injection of the skin. A slough of the size of half a crown occurred spontaneously on one buttock. The albuminate was applied; the slough did not extend, but sepa-

rated in two days, and the wound was healed within a fortnight. The patient died shortly after. This slough, if not treated, would in all probability have rapidly extended in the usual way and have been a great source of annoyance to every one connected with the case.

The advantages of the dressing are :

- (1) Infrequency of dressing in common with all powerful germicides.
- (2) Simplicity.
- (3) Powerful deodorizing qualities.
- (4) Absence of all irritating properties.
- (5) Small cicatrice that is left.

#### RECENT PROGRESS IN THE TREATMENT OF CHANCROID.

The multitude of remedies constantly suggested, advised, or urged in the treatment of chancroid is an indication of the degree to which this form of venereal sore can be at times rebellious. The most obstinate form of the chancroid is that designated as phagedenic, and the various modes that may be employed in its treatment have been reviewed at length in the *Journal of Cutaneous and Venereal Diseases* for February, 1886, by Dr. CHARLES W. ALLEN.

Recently Spillman, of Nancy, has treated several cases of this variety by first scraping thoroughly with the sharp spoon or curette, excising the undermined edges with scissors, cauterizing with the thermo-cautery, and dressing with diluted liquor of Van Swieten. Among the cases so treated was one of a medical student who had inoculated himself with the pus of a soft chancre on the anterior surface of the thigh. The thigh, lower part of the abdomen, and the scrotum became involved in an extensive phagedenic sore.

Various forms of treatment, from the use of iodoform to prolonged hot baths, were tried, with no effect.

The treatment by scraping, etc., was rapidly followed by a cure in this as in the other cases.

To abort soft chancres, Hebra advises as follows :

Thoroughly cleanse the sore, treat with a preparation of potash-soap and spirits, dry carefully, apply pure salicylic acid, and cover with a plaster.

This treatment succeeds best when the application is renewed on two succeeding days, and the sore suppurates freely. After three days, a white scab covers the sore.

An emollient ointment is now to be spread on lint, and applied. Under this the scab

speedily separates, and the wound heals without any bubo formation.

Iodoform is one of the most valuable applications in the slowly destructive forms of chancroid. Its use, however, in private practice is almost impossible, unless in some way the odor be destroyed or disguised.

Men object to it from reason of its *give-away* perfume, and public women will not submit to its application, as it keeps the men away from the house.

Only in the *virtuous*, therefore, can it be used pure without opposition. Iodoform has now so wide a range of application outside of venereal diseases that it is to be hoped these prejudices will soon disappear. This may, perhaps, be accomplished by deodorizing the iodoform, various formulæ for which have been already published in the *GAZETTE*.

Dr. Allen has recently called attention to the beneficial action of pyrogallic acid in the treatment of chancroids. This was first recommended by Vidal, of Paris, whose good results led others, among whom were Terillon and Mauriac, to make extended trial of the drug. Vidal recommended a powder composed of one part of the acid and four of starch. Dr. Allen has used and recommended the application of the pure powder to be first applied and covered over with a layer of traumaticine, or a solution of pyrogallic acid in collodion.

Of all caustics, the hot iron or thermo-cautery is probably the best for the majority of cases. With it we produce just the amount of cauterization we desire.

It can be used where other caustics would be dangerous, as in the vagina.

The pain produced, though severe, is of much shorter duration than that from chloride of zinc or nitrate of silver.

Since the introduction of cocaine into venereal surgery, the Paquelin cautery has lost its terror for the patient. Bono (*Gaz. delle Cliniche*, ii., 1885) says, "In cauterization, cocaine showed every desirable analgesic property of a sufficiently long duration."

Latouche (*Rev. de Clinique Méd.-Chirurg.*, January, 1885) strongly favors the thermo-cautery at a dull red heat, especially for chancroids of the vagina and neck of the uterus. He gives a number of cases in which the cure was complete in from eight to thirty-three days.

Dr. Aubert, of Lyons, has recommended prolonged hot baths as a means of treating chancroid.

Martineau and Lormand have carried out

some experiments at the Lourcine Hospital in Paris, on the effect of baths at about 104° F. on chancroids and buboes.

They found that in all the cases the virulence quickly disappeared, and that auto-inoculation gave negative results after one or more baths in all cases excepting one, where the chancroid was within the urethra.

They approve of the treatment for severe cases, finding it quite practical, and that it hastens the cure in all cases.

Wet compresses should be put upon the patient's head while in the bath, and an attendant be present for fear of syncope. It is not necessary to submerge the whole body.

*Sponge-Grafting.*—Dr. Pokrovsky applies fine slices of the best Turkish sponge, washed in a three per cent. solution of carbolic acid, to chancroids and chancroidal buboes, and finds that this treatment brings about rapid cleansing and healing in about ten days. In syphilitic cases, the sponge-dressing gives rise to rapid healing only after the virus has been mitigated by specific treatment; otherwise the application of sponge-grafting causes disintegration of the tissue.

#### THE CURE OF SPASMODIC ASTHMA WITH ELECTRICITY.

DR. E. PAGET THURSTAN reports in the *Brit. Med. Journ.*, January 16, 1886, the case of a man, aged 42, with a gouty history, who had been for a long time suffering from spasmodic asthma, for which he had consulted a number of physicians and had taken a large variety of patent medicines without relief. The attacks of dyspnoea commenced about 3 or 4 A.M., lasting till about 8 or 9 in the evening, and were very severe. There was a distinct cardiac impulse in the epigastrium; the area of cardiac dulness was increased, and extended lower and to the right of its normal position. The aortic sounds were not very loud, and were heard only to the right of the mid-sternal line. There was no murmur or reduplication of sounds. The pulsation of the carotids was very distinct. Ronchi were audible over the subclavian region on the right side, and very occasionally on the left, but resonance was normal. There was some enlargement of the liver and spleen. The bowels acted regularly, but he had a feeling of fulness and drowsiness after meals, and flatulence; latterly these had been better, as he had been omitting cabbage and green vegetables, cheese, pastry, etc., from his dietary, having discovered, by experience, that a supper including

these was a certain prelude to a severe attack of dyspnoea. He had always been moderate in the matter of drinking.

On March 24, 1884, after using an interrupted current with a bichromate of potassium cell daily for a fortnight along the edge of the sterno-mastoids, from the level of the jaw to the sternum, he was free from dyspnoea; but the pulsation of the carotids in the neck continued, and rhonchi were still to be sometimes heard under the right clavicle. He had not been free from attacks for so long a while since November, 1883; he could now run uphill without distress.

#### EFFECT OF NITRITE OF AMYL ON THE BLOOD-PRESSURE.

The influence which inhalations of nitrite of amyl exert on the arterial pressure is usually thought to be a lowering of the same. The investigations and direct measurements of DR. SCHWEINBURG (*Centralbl. für Med. Wiss.*, January 2, 1886) with Basch's sphygmograph, however, brought out different results.

The blood-pressure was seen to rise after inhalation of the drug, at the time when the well-known symptoms, reddening of the face, sensation of warmth, pulsation of the carotid arteries, etc., set in. This apparent contradiction between the ordinary assumption and Schweinburg's researches this observer explains by the statement that nitrite of amyl given in large quantities, or in small but repeated doses, produces a reduction of the pressure, but after small quantities, such as are exhibited for therapeutic purposes, a transitory rise takes place. Hence care must be taken in cases in which a sudden rise of pressure would be dangerous.

#### LARGE CERVICAL SPINA BIFIDA UNDERGOING SPONTANEOUS CURE.

At the meeting of the Clinical Society of London, held January 8, 1886, MR. CLUTTON read a note of a case of the above nature (*Medical Press*, January 13, 1886).

The patient was the younger brother of a case in which he had successfully treated a lumbar spina bifida by the glycerio-iodine injection, and the particulars of which were reported to the Society in 1862. Both cases were shown as living specimens last November. The mother had had ten children, of which the ninth and tenth were affected as above mentioned. The latter was born in

1885 with a spina bifida in the cervical region of the spine, of which the size and position were demonstrated by means of a photograph. It was six and one-half inches in diameter, and rather coneiform in shape, with the apex directed upwards. The coverings were thin but completely covered with skin. It could be reduced in size by pressure, and filled again when the child cried. A considerable aperture could be felt in the vertebral arches. It was thought to be a simple running goitre from the fact that there was a perfect cutaneous covering without any ulceration, median furrow, or central depression, that it was translucent in every part of its surface, and that there were no paralytic symptoms. When five weeks old the cyst was found to be much smaller, and its coverings quite soft and flaccid. No treatment of any kind had been adopted, and yet the communication with the interior of the vertebral canal had become occluded. From that time till December it diminished in size, when the child died from causes unconnected with the spina bifida. Mr. Shattock showed the specimen which was obtained from the post-mortem examination.

MR. GOLDING BIRD said he should like to ask of what the child died, as it seemed to him the photography was as fatal as the operation.

MR. R. D. PARKER thought this was not a straightforward case of spina bifida. In the report of the committee last year appointed to investigate spina bifida there were cases of a precisely similar kind. Mr. Thomas Smith and Mr. Holmes had drawn similar conclusions to himself. He thought the attempt of spontaneous cure was not so successful as when injection had been adopted. Many recoveries had followed treatment, and he thought, therefore, that treatment was more favorable than spontaneous recovery.

A MEMBER asked what changes did the tumor undergo? It was said that at a certain period the tumor began to shrink. Were the changes due to healthy processes, or to inflammatory changes? He had assisted Mr. Holmes at an operation in a case similar to the one under discussion. The tumor was situated very high in the dorsal region. The child was a few weeks old. A ligature was placed round the tumor, which was removed. The state of the patient became very critical, and the child died in a few hours.

MR. CLUTTON, in reply, said the child died from causes unconnected with the cyst,—from diphtheria or some intercurrent affection. Mr. Parker had said it was not a pure case of spina

bifida, it might be a meningocele or myelocele, but these cases of spina bifida vary, some as meningocele sometimes contain the cord, and sometimes an expansion of the cord. Had the case survived he believed the tumor would have become quite small, and undergone spontaneous cure. It might have been laid open without endangering the life of the child. No difficulty presented itself in the diagnosis. There was tremendous impulse on coughing, the thing had become considerably smaller, and finally it gave no impulse when the child cried.

#### ADMINISTRATION OF QUININE IN CASES OF IRRITABLE STOMACH.

That quinine requires to be administered in cases which are accompanied with irritability of stomach and bowel is shown by Dr. Aitken's attempts (Report, British Medical Association, at Cardiff, 1885) to render the subcutaneous injection of the drug innocuous. Doubtless, too, in zymotics, especially typhoid, where putrefactive (germs) fermentation goes on to a great extent in the stomach, frequently repeated doses of the drug would retard or destroy the processes, while not interfering with digestion. MR. JOHN REID (*Australasian Medical Gazette*, December 15, 1885) proposes, therefore, for cases of irritable stomach, to dissolve quinine in citric acid (glycerin may be added), and made into an ordinary mixture. Dispense bicarbonate of sodium in powders, more than sufficient to neutralize the citric acid *of a dose*. Add the soda to milk in a glass, stir well, then add dose of quinine mixture, still stirring. The effervescing draught, somewhat resembling sparkling koumiss, will be tolerated by the stomach, even when the tongue is red and irritable; the tongue, after the draught, changing its character.

AN ATLAS OF CLINICAL MICROSCOPY. By Alexander Peyer, M.D. Translated and edited by Alfred C. Girard, M.D. Ninety Plates, with one hundred and five Illustrations, Chromo-Lithographs. New York: D. Appleton & Co., 1885.

"While engaged in the practice of medicine I had recognized the necessity for a physician to become familiar with the microscope if he made any pretension to scientific treatment."

This, the second sentence of the author's preface, echoes the experience of not a few.

From being an exceptional accomplishment, familiarity with the microscope and its clinical applications has become a necessity,—an additional refinement of sense for every progressive practitioner. What a man actively engaged in the routine of practice *may* do the atlas before us bears witness; for its author tells us the plates are selections from a large collection, which grew within a few years as the fruit of the “pleasant habit” of carefully sketching everything met with in his clinical examinations.

The subjects illustrated are divided into nine chapters,—Blood, Mammary Secretion, Urine, Sputum, Intestinal Contents, Contents of Stomach, Contents of Abdominal Tumors, Secretion of the Female Sexual Organs, and Micro-Organisms producing Disease.

The ninety plates are accompanied by concise descriptions of varying merit, the text being at times of but slight moment, at others pregnant with facts.

The first three plates—twelve figures—are devoted to the blood, a few figures illustrating its normal conditions, while the remainder represent a number of pathological changes. The forms and coloring of the hæmin crystals by no means accurately represent these important subjects.

The subject of the following plate, with four figures, is the mammary secretion, in health and in inflammatory conditions.

Chapter III.—Examination of the Urine—is by far the most elaborate of the book, claiming over two-thirds of the entire number of plates.

The section is introduced with a concise review of the general qualities of the urine, followed by a number of the more important tests for albumen and sugar. Of the thirty-six plates illustrating urinary examinations proper, nineteen are acceptable representations of crystals of greater or less importance. Seldom, however, is it that uric acid appears as resplendent in gorgeous colors as do the crystals of some before us.

Plates 27–44 figure the forms of tube-casts, and are second to none in importance. If we pass the last of these with a sense of disappointment, it is, possibly, but a reassertion of the conviction that drawings never convey the exact appearance of the more delicate forms of casts as seen under the instrument. The too-pronounced and often harsh outlines, and the loss of the peculiar transparency of the hyaline varieties, do not mark these drawings as favorable exceptions.

The remaining twenty-six plates of the

chapter on the urine illustrate hemorrhagic, catarrhal, and inflammatory conditions of the kidney and urinary tract, including a rather prolix account of “Spermatorrhœa” through eleven plates. Among these latter the one representing the hyaline cylinders sometimes found in spermatorrhœa is the most interesting, as indicating a possible source of error in the diagnosis of grave kidney-trouble from the presence of apparently hyaline tube-casts.

After so generous an allotment of plates to comparatively unimportant conditions of the urine, the discussion of the important section relating to sputum, in fourteen plates, at least four of which have little value, seems meagre.

Plate 74, representing the Charcot-Neuman—so-called asthma—crystals will be examined with interest. A series of drawings of the sputum in the various stages of pneumonia would have made an acceptable addition; likewise further illustrations of phthisical expectorations would have been of interest.

Of the four plates relating to the stool, our author contents himself with a single drawing of objects found in normal fæces, in addition to the presence of parasites.

Of the many interesting conditions regarding which valuable information may be obtained by microscopical examination, he has nothing.

Plate 85, after Koch, represents the “comma” bacillus of cholera. A useful supplementary drawing would have been one showing *other curved* bacilli under identical amplification, demonstrating the *differences* between these common forms and the supposed pathogenic organism described by Koch.

Four plates follow, with contents of the stomach, including vomit in chronic catarrh, contents of an ovarian cyst, and leucorrhœa of pregnancy as subjects.

The final plate represents the micro-organisms supposed to be genetic of pyæmia, typhoid fever, pneumonia, and gonorrhœa, it being a fair reproduction of part of the well-known figures by Friedländer.

Considered collectively, the drawings are generally well executed: an occasional inferior plate is offset by the few of especial merit.

The wisdom of devoting so large a portion of the illustrations to the urine, at an apparent expense to the fulness of other equally important subjects, may be questioned. A judicious economy of space by the union of the salient features of several plates in not a few instances, would offer an opportunity to make

additions which would enhance the practical value of the book as a clinical guide.

In conclusion, we cannot forbear expressing our protest against the omission of the amplification of the figures. The term "weak" power is too vague to convey any definite ideas to those little acquainted with microscopical examinations,—the very class for whom these plates have the most value,—while "with Hartnack 7 or 9" to many American readers will be scarcely less unsatisfactory. As a specimen of book-making the volume is very attractive, the imprint of its well-known publishers being sufficient guarantee for the excellence of the mechanical execution.

TRANSACTIONS OF THE ACADEMY OF MEDICINE IN IRELAND. Vol. III. Edited by William Thomson, M.A., F.R.C.S.

Dublin: Fannin & Company, Grafton Street; London: Ballière, Tindall, Cox; Edinburgh: MacLachlan & Stewart. 1885.

The Academy of Medicine of Ireland is an institution with which we confess we were unacquainted until the volume now before us came into our hands. It appears that this society was organized in the year 1882, and the present Transactions, having the date of 1885, is the third of its series. If the first two volumes are as valuable as the present, this new medical society must be considered to have taken a foremost rank among the similar societies of the world. It seems to us extraordinary that in this great country of America, with its alleged sixty thousand doctors, we cannot have one medical society whose transactions shall favorably compare with that put forth by this lusty medical infant of the evergreen island.

The book before us itself contains about five hundred pages, which are chiefly filled by short articles covering almost the whole field of practical medicine, and in many places entering upon the domain of hygiene, anatomy, physiology, and other sciences allied to practical medicine. The first paper is an elaborate article by Mr. Walter G. Smith, upon Lupus and its treatment. Then there comes a report of a case of Anuria, by Mr. Walter Bernard; then an article upon Hereditary Amaurosis, by Mr. John B. Story; next an article upon Cholera in India, by Surgeon-Major Hamilton, in which the preventive medicine, so called, of the disease is especially considered. Mr. Hamilton is not much of an enthusiast, either as regards the prevention and treatment of cholera, confessing that "at present the outlook as regards the pre-

vention and treatment of cholera is dark indeed."

Space is lacking in which to even mention, let alone to discuss in detail, the very many papers, the scores of articles which are here collected together. We can only note a few points. In an interesting article Dr. J. M. Finny discusses Hyperpyrexia in rheumatic fevers, and the cases of so-called Cerebral Rheumatism, but fails, as it seems to us, to comprehend the disease through lack of clear recognition of the fact that there are two or three essentially different forms of this Cerebral Rheumatism, and through failure to apprehend the modern theory in regard to the nervous origin of fever. It is plain that he knows the work of Dr. H. C. Wood simply by references to it which have been made from time to time in European medical journals. The theory is not, as Dr. Finny seems to think, "that the liberation of heat on the surface of the body is controlled or restrained in fever through disorders of the nerves, so that by retention the temperature rises;" but the theory is that fever is due to a disturbance of the relation between the nerve-centres which control the production and the dissipation of animal heat, and that there is also such a paralytic condition of the inhibitory heat-centres that chemical movements in the stored tissues of the body occur more rapidly than in health.

An interesting paper is that by Dr. Cruise, on Contrexeville and Royal-les-Bains; a paper which may be read with great advantage by almost every American physician who has patients suffering from gouty disease desirous of visiting European springs. Mr. Charles B. Ball has an exceedingly interesting article on the very frequent development of papillomata on the hands of workers in carbolic acid factories and their conversion into malignant infiltrating epithelioma; a paper which finds its corroboration and support in an article by Mr. John B. Stewart, describing the production of epithelioma of the eyelids by irritation from crude carbolic acid. We shall conclude our review of this very interesting book by remarking upon a paper by P. S. Abraham in regard to the habit of eating themselves up sometimes developed in carnivorous animals during confinement. A fine lioness in the Zoological Gardens in Phoenix Park, Dublin, was discovered to have devoured some six inches of her tail, hair, skin, bones, all complete. A week or two later, one night she again took to eating her unfortunate caudal appendage, and so continued until the

butt was so short and uncomeatable that the beast was forced to let it alone. A month or two later she began at one of her forepaws, and continued to gnaw it until there was but little left of it; finally, the agony from the mutilated foot and tail became so great that the beast was shot. During the whole period the animal seemed to be in perfect health, her excretions were normal, her fur, flesh, and appetite in excellent condition. Changes of food and various other expedients were tried in order to save the lioness, which was valuable and had had three sets of cubs. This incident led Mr. Abraham to correspond with the authorities of almost every zoological garden of importance of Europe; he found that although the occurrence is rare, self-eating does happen every now and then with almost all of the carnivora. A very curious fact is that monkeys quite frequently feast upon their own tails. Parrots also have been noticed to devour their feathers and flesh. Mr. Abraham is inclined to believe, along with some of the superintendents of the gardens, that these animals are insane, and that the perversion of taste may be looked upon as one of the manifestations in the lower animals of that protean affection which we call hysteria. On the whole, we think it would not be a bad thing if some of the hysterical females belonging to the species *Homo* (variety *Americana*) would imitate the lower animals in this disappearing down their own throats.

TRANSACTIONS OF THE TEXAS STATE MEDICAL ASSOCIATION; Seventeenth Annual Session, Houston, Texas.

Austin, Texas: Printed for the Texas State Medical Association, 1885.

This is a well-printed book, containing the usual rhetorical addresses seen in works of its class, and chiefly valuable on account of a number of cases which are reported in it. The most remarkable article seems to us to be that of Dr. M. Ramsdell, of Lampasas, Texas, in which are reported ten cases of serious acute attacks asserted to be due to biting from spiders. The symptoms seem to be nausea and vomiting, increase of temperature, sharp, shooting pains, or burning pains, in the back, head, and limbs, with profuse sweating, and more or less general depression. None of the cases died, but one woman, who was furiously delirious for twenty-four hours after the bite, was seriously affected for two weeks. In a book like the present, with its limited circulation outside the district it

represents, reported cases were in the past practically buried so far as concerns the general medical profession of the world, but now, thanks to the *Index Medicus*, facts worthy of remembrance are marshalled into their line even though they belong to the cohorts of a remote region.

ORGANIC MATERIA MEDICA AND THERAPEUTICS. By James Young Simpson, M.D.

New York: J. H. Vail & Co.

This is a book of 328 small pages occupied with handsomely displayed type, arranged in greater part in short sentences. It is a brochure which is offered as a high road to the regions of the student's Paradise, to the gardens of professional preference which lie beyond the dark gates of examination. As a work for cramming it may have some value, but that the committing of its whole contents would in any degree prepare a man for the practice of medicine admits of grave doubts. Possibly, however, he would be a little better off than if he had never studied the subject at all, but he certainly would not even reach that first mental condition which is the vestibule to the temple of knowledge, namely, conviction of the extent and depth and breadth of his own ignorance.

THE POPULAR SCIENCE MONTHLY.

This is a very valuable magazine, both interesting and instructing. We are informed that General John Newton, Chief of Engineers, United States Army, originator of the plan and director of the work, has prepared a complete account of the operations for the removal of the obstructions at Hell Gate, from their beginning to the explosion of Flood Rock, in October last, which will appear with full and new illustrations as the leading article in the February number.

THE December number of Wood's Library of Standard Medical Authors is a reprint in one volume of two books by Dr. W. R. Gowers, of London, of *Diseases of the Brain* and of *Diseases of the Spinal Cord*. The original editions of these works have been so thoroughly reviewed, and are so well known to the reading medical public, that of course no further notice of them would be at present in order.

REVUE SCIENTIFIQUE.

The following is a summary of the table of contents of the *Revue Scientifique* for the past month:

December 26, 1885 :

*Public Works.*—The Port of Marseilles. By M. de Flaix.

*Psychology.*—Consecutive Images and Visual Memory. By M. A. Binet.

*Miscellany.*—The Colonial Future of France. By M. Janssen.

*Chemistry.*—Chlorinated Ethyl Benzines. By M. Israti.

*Proceedings of the Academy of Sciences of Paris.*

*Correspondence and New Inventions.*

January 2, 1886 :

*Progress of the Sciences.*—Contemporary Science. By Huxley.

*Psychology.*—Intelligence of Animals. By M. J. Delbœuf.

*Physiology.*—Lessons on Animal Heat. Fishes and Temperature. By M. Richet.

*Astronomy.*—The New Star. By M. Barré.

*Zoology.*—The Organs of Flight in the Animal Series.

*Book Notices.*—Diseases of the Nervous System. By M. Grasset.

*Proceedings of the Academy of Sciences of Paris.*

*Correspondence and New Inventions.*

January 9, 1886 :

*The Scientific Congress.*—Criminal Anthropology in 1885. By M. E. Ferri.

*Miscellany.*—Russian Surgeon at Sebastopol. By Pirogoff.

*Physiology.*—Lessons on Animal Heat. By M. Richet.

*Zoology.*—Development of the Genital Organs in Gasteropods. By M. Rouzaud.

*Book Notices.*—Diseases of the Ear. By M. Gellé.

*Proceedings of the Academy of Sciences of Paris.*

*Correspondence and New Inventions.*

January 16, 1886 :

*Biology.*—The History of General Anatomy. By M. Duval.

*Physiology.*—Lessons on Animal Heat. By M. Richet.

*Psychology.*—Religious Exaltation in the Orient. By M. Zambaco.

*Miscellany.*—Balzac and Chemistry. By M. Grimeaux.

*Book Notices.*—Hygiene in Dwelling-Houses (F. and E. Putzeis) ; Legal Medicine, Medical Jurisprudence, and Toxicology (M. Le-grande du Saulle).

*Proceedings of the Academy of Sciences of Paris.*

*Correspondence and New Inventions.*

January 23, 1886 :

*Geography.*—The New Congo State. By M. Plauchut.

*Biology.*—The History of General Anatomy. By M. Duval.

*Geology.*—The Earthquakes in Algeria in December, 1885.

*Zoology.*—The Fossil Fish in Roumania. By M. Cosmovici.

*Book Notices.*—Medical Zoology (M. R. Blanchard) ; Magnetism and Hypnotism.

*Proceedings of the Academy of Sciences of Paris.*

*Correspondence and New Inventions.*

### PALATABLE PRESCRIBING.

To the Editors of the THERAPEUTIC GAZETTE :

GENTLEMEN :—The article by Dr. Martin, of Chicago, on *Palatable Therapeutics* suggests to my mind more difficulty than it removes. If we are to contest with the homœopath, who can readily render a prescription which, medicinally, contains nothing, both pleasing to the palate and gratifying to the man who holds the purse-string, we might as well give up the race at once.

Let all honor be given to the French pharmacists and physicians who have long taken the lead, by innumerable ingenious devices, through which medicines are presented in agreeable form, while we freely avail ourselves of the latest advances of pharmaceutical chemistry of our own day and our own land.

But the homœopath has entered a domain wherein it is hopeless that we should think to contest. Our first duty is to deal with candor and to speak the truth to our patients ; our first and constant purpose is to save, to cure, to relieve. When we have decided what is the surest and readiest means to this end, we may make our presence and interposition as pleasant as possible.

It is far from certain that we always have the full energy and efficacy of the drug given us in its principal alkaloid or glucoside. If the patient's stomach positively refuses to take our few drops of tr. digitalis, we will do our next best for him with digitaline ; but not because his palate is offended.

I yield to no one in my admiration of the elastic capsules of the balsams. But the patient must have learned to swallow a pill before he can take medicine in this form, for

the capsule cannot at option be chewed or swallowed or spit out, with equal present impression and subsequent result, as if it were a homœopathic pill. Still again, too often the weak stomach shows offence if ten minims of a sharp balsamic oil be suddenly discharged into its cavity, and the patient, whose homœopathic neighbor we are striving to please, will quite likely complain if he is directed to take a wineglass of milk or broth with every capsule. It were no more trouble to swallow a turpentine emulsion at first hand.

Once more, I contend that it is not often feasible to administer the alkaline bromides in capsule-form, considering the usual change. Moreover, what are we to do towards gratification of appetite when it comes to the occasional massive dose of potass. iodide which Séguin and Jonathan Hutchinson, *e.g.*, urge nowadays? Many of us think we find frequent occasion to order strychnine and phosphorus in much larger doses than the gr.  $\frac{1}{80}$ ,  $\frac{1}{100}$ ,  $\frac{1}{120}$ , which the obliging New York pill-makers turn out by the myriad annually for the profession. The gr.  $\frac{1}{18}$  to  $\frac{1}{14}$  of one or the other hardly makes a pleasant impression upon the patient that has been nurtured on homœopathic sweetmeats.

It will not come amiss to recall, in this connection, the counsel which Sydenham gives in his first preface: In the capacity of *Homœopath* (*δμοιοπαθής*), says this great writer, ought every physician to enter the chamber of his patients,—writing, as he did, a good hundred years before Hahnemann stole and prostituted the word,—that is, *as a fellow-sufferer and in full sympathy*.

Surely, when the situation is reversed, as it is likely with all of us to be some time, and we call in the doctor, we shall wish our physician to give first and chief attention to something else than rendering himself and his remedies flattering and sweet.

Yours faithfully,

HENRY M. FIELD.

#### THE AXIS-TRACTION FORCEPS.

To the Editors of the THERAPEUTIC GAZETTE:

GENTLEMEN:—In the THERAPEUTIC GAZETTE of December 15, 1885, I notice an editorial on the above subject, which is almost an exact copy of one that appeared in the *Journal of the American Medical Association*, September 26, 1885, to which I have duly replied in the same journal of October 17 and October 31. Should any of your readers take the least interest in this matter, I trust it

may save you the trouble of further copying by referring them at once to the above journals. In every article I have written on this subject, in every verbal explanation of this instrument I have uttered, I have invariably and without any exception credited the button-hole joint to Dr. Felsenreich. To two disingenuous criticisms I have categorically answered, and in the most courteous terms corrected misrepresentations, and stated that I took the button-hole joint from Dr. Felsenreich.

The accusation contrary to this fact is again reiterated, and I pronounce it *palpably but unqualifiedly and wilfully false!*

Respectfully, DR. L. E. NEALE.

BALTIMORE, January 3, 1886.

[In order that no injustice may be done, we print this letter of Dr. Neale's. The editorial alluded to by Dr. Neale and that which appeared in this journal were written by the same hand, hence the resemblance between them. Our own editorial was written before the replies of the doctor in the *Association Journal* were read. We cannot occupy the columns of this journal with any further controversy concerning the matter. On the 18th of December an article was read by Dr. W. W. Jaggard before the Chicago Gynæcological Society, in which the whole subject has been traversed. This article has at present writing not yet appeared, but we are informed that it will be published in a few days; to it readers desirous of following out the matter are referred.—EDS.]

#### GONORRHEA IN WOMEN.

To the Editors of the THERAPEUTIC GAZETTE:

GENTLEMEN:—The article in the December number of the GAZETTE, entitled "On the Importance and Diagnosis of Gonorrhœa in Women," so nearly describes a condition found in a young woman who called at my office a few months ago to be treated for gonorrhœa, that I will give a short history of the case. The patient said she was treated for the disease a short time previous by a physician of Indianapolis, Indiana, and was dismissed with the assurance that she was cured. Acting on this assurance from the doctor, to her dismay she brought misfortune to one of the other sex.

A thorough examination of the whole surface of both the vagina and the vulva revealed no trace of the disease. On turning my attention to the cervix, there I found pus,

to every appearance gonorrhœal, with a diseased surface extending to the depth of about half an inch. After pursuing a course of treatment which consisted, principally, in the application of nitrate of silver in stick form, the patient was dismissed with every appearance of being cured.

Respectfully yours,  
H. L. PRATT, M.D.

ELGIN, ILLINOIS, January 2, 1886.

#### CHLOROFORM TREATMENT OF TAPEWORM.

To the Editors of the THERAPEUTIC GAZETTE:

GENTLEMEN:—The question as to whom belongs the credit of first employing chloroform for the expulsion of tapeworm seems to interest quite a number of your readers. I would therefore state that before the class of the Ohio Medical School of 1864-65, Prof. Blackman, when lecturing on the anæsthetic properties of chloroform, mentioned in a humorous way that it had been employed in drachm doses, followed by castor oil, for expelling tapeworms. Many of the class made a note of it, and if they will refer to their old memorandum-books, will no doubt bear me out in my statement. So we must go back prior to 1864 to find the originator of this method of treatment.

Respectfully yours, etc.,

C. GERSTMAYER.

TERRE HAUTE, IND., January 22, 1886.

---

### Notes and Queries.

---

#### MUSSEL-POISONING.

An unfortunate instance of poisoning by mussels (*Mytilus edulis*) recently took place at Wilhelmshaven (*Medical Press*, November 25, 1885). Two vessels were taken into dry-dock on October 17 for the purpose of cleaning, the sides of which were covered with the common mussel. The dock work-people collected large quantities and took them home, where they were prepared and eaten. Very shortly after partaking of them symptoms of poisoning set in, nineteen people being attacked,—thirteen men, five women, and one child. Nine of the cases were serious. Within one and three-quarter hours after eating the mussels the first death took place, and three others followed within four and a half hours. The Kreisphysikus, Dr. Schmidtman, made a post-mortem examination in the last case. The condition met with corresponded to irritant

poisoning,—redness and swelling, and in many places complete detachment of the mucous membrane of the intestine. The remains of mussels were among the intestinal contents, but no older masses. The spleen was swollen and thickened. Dr. Schmidtman attributed the poisoning to a ptomaine, but Virchow could not agree with this. He is, however, inclined to the view that it was due to an alkaloid. Portions of the bodies and various quantities of the mussels were submitted to Professors Virchow and Koch for examination, and these gentlemen, supported by Professors Eilhard, Schulze, Salkowski, and Wolff, instituted experimental investigations with them, the result of which they have reported. Both the flesh and decoction contain the poison, which is weakened neither by heat nor by alcohol. Small animals were killed by it in a quarter of an hour. The poison is said to act like curare, by paralyzing the motor nerves. Virchow places the poison in the series of fish-poisons that develop in both dead and living fishes. He also reported that Koch had discovered several characteristic bacilli, but that he had not succeeded in propagating them, so that no definite judgment could be pronounced upon them.

Professor Salkowski reported that all the active extracts of the poison were at once rendered inactive by moistening with a drop of sodium bicarbonate. From this he concludes that the poison is a fugitive alkaloid that had as yet not been isolated. The ships were not copper-bottomed, so that there could be no question of the mussels being rendered poisonous by metallic absorption.

The Paris correspondent of the *British Medical Journal* (December 12, 1885) refers to a somewhat similar case reported by Dr. LABORDÉRIE. The patient was an itinerant dealer in vegetables; he was seized one night with violent pain in the mouth and pharynx, and respiration became difficult. The patient sat up or walked about all the night. The buccal mucous membrane and the tonsils were excessively red, and the tongue was white. Diarrhœa and vomiting set in during the night; the neck became stiff and tender; the heart and lungs were perfectly normal, and all symptoms of gastric disturbance were absent. The patient, two years ago, had an attack of multi-articular rheumatism. The evening before he was taken ill he had eaten plentifully of mussels. M. Labordérie remembered the connection between urticaria and rheumatism, noted by M. Potain in a clinical lecture, but admitted the possibility

that his patient was suffering from urticaria, provoked by eating mussels. He prescribed an emetic and a draught containing 60 grains of salicylate of sodium. The pains in the mouth and pharynx disappeared, breathing became normal, and an eruption of urticaria covered the patient. M. Potain, in one of his clinical lessons, said that he had twice experienced the same symptoms after eating mussels, and had twice suffered from urticaria as the result of drinking seltzer-water on a very hot day.

#### QUILLAIC ACID.

What is ordinarily known in commerce under the name of saponine is not a distinct substance, but a mixture of various organic and inorganic matters. The toxic properties of the saponine of commerce are, according to KOBERT (*Gazette Méd. de Paris*, No. 42, 1885), due to the presence of two principles for which he proposes the names of quillaic acid and sapotoxine. To obtain the first of these a decoction of quillaja bark is precipitated by neutral acetate of lead; the precipitate, after being well washed, is freed from lead, reduced by boiling, and the residue dissolved in absolute alcohol; after filtering and evaporation, the residue is again dissolved in a mixture of five parts of chloroform to one part of alcohol. By these means a great part of the coloring matter is avoided. On the addition of ether to this filtrate, quillaic acid is deposited in snowy flakes, which are dried over sulphuric acid. The poisonous property of this acid and its saline combinations is enormous. It is only necessary to inject  $\frac{2}{1000}$  of a grain for each pound of body weight into the veins of a dog or a cat to produce death, while 30 grains administered by the mouth are safely borne. By heating this acid in contact with a solution of baryta the poisonous properties are entirely lost. Kobert is therefore led to believe that saponine is an inert product of the transformation of quillaic acid.

#### TEREBENE.

Some uncertainty appears to prevail respecting a material recently introduced, under the name of terebene, to the notice of medical men, for inhalation in cases of winter cough and other purposes, which we are informed has been a cause of inconvenience in several instances. DR. MURRELL'S paper on the use of terebene appeared in the *British Medical Journal* of the 12th of December last, and was abstracted in our last issue, and

in it he referred to the pure form of the substance that has been well known to chemists for many years. He spoke of having used terebene during the last five years with excellent results in numerous cases of winter cough. That substance he correctly described as a product of the action of sulphuric acid upon turpentine oil, a clear colorless oily liquid, having an agreeable odor like that of fresh-sawn pine wood, which though not miscible with water could be given upon sugar, as the dose is small. This description of a substance well known to chemists would have been sufficient, but unfortunately Dr. Murrell added that the substance he referred to was not the same as "the patent medicine sold under the name of 'Terebene.'" The following week a letter appeared in the same journal from DR. BOND, of Gloucester, in which he spoke of himself as being the person who originally brought terebene under the notice of the profession, and further led to the inference that the manufacture of terebene was the subject of a patent. Hence has arisen the inconvenience above referred to, and as several communications have appeared on the subject, we think it desirable to draw attention to the recorded information respecting terebene and its products, as well as to the patents of Dr. Bond for certain applications of this material (*Pharm. Journ. and Trans.*, January 16, 1886).

The hydrocarbon having a composition represented by the formula  $C_{10}H_{16}$ , which is the chief constituent of turpentine oil and termed terebenthene, as obtained from French turpentine (*Pinus maritima*), has a specific gravity of 0.864; its boiling-point is  $161^{\circ} C.$ , and it has a specific rotatory power =  $-42.3^{\circ}$ . English turpentine oil (*Pinus australis* and *P. tæda*) contains a corresponding hydrocarbon termed australene, having the same specific gravity and boiling-point as terebenthene, but it differs from that in being dextrorotatory, the specific rotatory power being =  $+21.5^{\circ}$ . Under the influence of heat both hydrocarbons undergo alteration, the rotatory power being reduced and the boiling-point raised; the change that takes place being a modification of the molecular structure, giving rise to isomeric and polymeric products. One of these products of molecular transformation of turpentine oil is the substance termed terebene, which Dr. Murrell has recommended for medicinal use.

According to the description given of that isomeric or polymeric modification of the chief constituent of turpentine oil, which has been

named terebene, it is an oily liquid having the odor of thyme oil, a specific gravity of 0.864 and a boiling-point of  $156^{\circ}$  C. Its chief peculiarity consists in its being optically inactive, while the hydrocarbons terebenthene and australene from which it is produced have a rotatory power. It is obtainable by the action of various reagents upon terebenthene, the one most effective for this purpose being boron fluoride, which, it is stated, instantly converts one hundred and sixty parts of terebenthene with great rise of temperature; but by this reagent other products besides terebene are produced, all of them agreeing in being optically inactive, but some having a boiling-point above  $300^{\circ}$  C. Concentrated sulphuric acid acts in a similar manner, but less energetically. To prepare terebene in this way rectified turpentine oil is to be mixed with one-twentieth part of oil of vitriol and the mixture left to stand for twenty-four hours. The clear liquid is then decanted off from the sediment and distilled, this operation being repeated several times until the product no longer acts upon polarized light. It is then washed with water and carbonate of sodium solution, dried over calcium chloride, and distilled. The same molecular alteration is produced by several acids, such as boric acid, and even acetic, citric, and tartaric acids, with the aid of heat, but the action is very slow. Zinc chloride acts in a similar manner at  $100^{\circ}$  C.

A polymerized oil called colophene, having a boiling-point of from  $310^{\circ}$  to  $315^{\circ}$  C., a specific gravity of .94, and an aromatic odor, is also produced, together with terebene in the process above described, as well as other polyterebenes of higher density and boiling-point, and all differing from turpentine oil in being optically inactive.

In the specification of Dr. Bond's patent for the preparation of disinfectants (1874, No. 1510, England) the application of terebene for this purpose is claimed as part of the invention, but the substance itself is spoken of as an isomeric derivative of turpentine oil that was then well known to chemists, and had been described in many chemical works. In the specification of a subsequent patent (1874, No. 3799) the application of both terebene and colophene for the same purposes is also claimed, and it is stated that the material distinguished in the specification by the name of "terebene" was to be understood as a mixture of the substances known to chemists as terebene and colophene. It is clear, therefore, that so far as these patents have anything to do with

terebene it is in regard to a matter quite apart from its application as a medicinal agent, and that there is nothing in the specifications of these patents to justify the application of the term "patent medicine" to terebene. A crude form of polymerized turpentine oil has been sold under the name of terebene, but it was not of such a nature as to be suitable for medicinal purposes, though it has been used to some extent as a disinfectant and deodorizer.

From what has been stated, therefore, it is evident that the preparation of terebene by the process above described may be carried out by any one that desires to do so without fear of interference with patent rights of any kind; and as the recommendation of this article for medicinal use by Dr. Murrell will no doubt create a demand for it, we have thought a statement of these facts and a description of the method of preparation would be useful to some of our readers.

#### *RANUNCULUS ACRIS AS AN EPISPASTIC.*

H. FROELICH (*Centrall. f. die Gesamnte Therapie*, October, 1885) states that fresh ranunculus taken internally acts as a powerful irritant to the entire alimentary canal, even producing severe inflammation, and that it seems to increase the secretion of urine. Externally, it also acts as an irritant to the skin. This latter property has been investigated by Froelich by rubbing up about three hundred grains of freshly-plucked flowers and blossoms, and then applying them, in the form of a poultice or of a dressing, to the skin. After an hour, the skin was reddened, somewhat painful, and after two hours, of a bright red color, swollen and tense. After the removal of the dressing, which was not in position more than two hours, a number of discrete, and later confluent blisters formed, so that on the fifth or sixth day the entire epidermis over the point of application could be removed; the wound healed again in ten to twelve days. This irritant action on the skin is slower of production than that of mustard, but is more intense, and is more comparable to that of the fly-blister.

#### *ACTION OF PELLETIERINE ON THE EYE.*

According to the Paris correspondent of the *British Medical Journal* (November 28, 1885), M. GALEZOWSKI read a paper before the Académie de Médecine on the action of pelle-

tierine on the motor nerves of the eye. His researches are based on the ocular disturbance which occurs in subjects who absorb pelletierine; they are affected with diplopia. The observance of this fact induced M. Galezowski to prescribe pelletierine when there is paralysis of the third and sixth pairs. Iodide of potassium and blisters have failed where pelletierine has cured; the preparation used is syrup of pelletierine, 1 gramme (15 grains) per 120 parts of syrup. From three to six doses were administered. Unfortunately, this substance is excessively dear. M. Galezowski hopes to meet this difficulty by administering pelletierine in subcutaneous injections.

#### ALCOHOLIC TREATMENT OF DISEASE.

In a paper recently communicated by MR. GEORGE STURGE to the Hospitals Association, some very interesting figures are given representing the consumption of alcohol in various London and provincial hospitals (*Med. Press and Circular*, January 6, 1886). From the examination of one hundred and forty reports of hospitals, chiefly in England and Scotland, Mr. Sturge ascertained that great diversity in the practice of using alcoholic drinks as part of diet exists, and in some cases this practice has very much decreased. It appears that the consumption of alcohol varies from ten shillings and seven pence per patient in the Brompton Hospital to ten and three-quarter pence in the Manchester Infirmary. In the Middlesex Hospital the amount per patient was four shillings and three pence, while presumably the same class of disease was treated in the same number of patients in the Westminster Hospital at two shillings a head. In the provinces the Cambridge Infirmary tops the list with an expenditure of six shillings and seven pence per patient, while the Manchester Infirmary, which deals with a class of patients much more likely to need stimulation, outlayed only a seventh of the money—ten and three-quarter pence—to produce similar results. To illustrate the possibility of working a hospital satisfactorily on a greatly reduced expenditure on alcohol, Mr. Sturge points out that in ten years the expenditure of the Middlesex Hospital on alcohol has come down from ten hundred and seventy-nine pounds to five hundred and forty-seven pounds, while that of the Manchester Infirmary has fallen in the same period from seven shillings and two and one-half pence per patient to ten and three-quarter pence. Mr. Sturge states that

at the London Temperance Hospital two thousand eight hundred and sixty-two patients were treated at a mortality rate of less than five per cent., but of course no safe deduction can be made from this statement until we know whether the cases treated were on an average of the same type and character as those in the general hospitals. We are, however, safe in concluding that there is "something rotten" in the hospital system which admits of these diversities of practice in the various institutions. If the Manchester Infirmary can do full justice to its patients on an alcohol allowance of ten and three-quarter pence, it is a monstrous abuse that Cambridge should waste six shillings and seven pence on an article which, if it be not necessary, is at best a luxury, and at worst, an injury to the patient. What right has any institution to beg for public charity, and when it receives that charity, to throw it away on an article which—judging from the experience of other institutions—seems to be no more useful in most cases than lollypops would be?

#### PILOCARPIDINE, A NEW BASE IN JABORANDI-LEAVES.

Merck has succeeded in isolating a third base from the leaves of the jaborandi. This body, which has been studied by HARNACK, who has given it the name of pilocarpidine, in its free state is a syrup, which, in the form of a nitrate, forms voluminous columnar crystals resembling those of saltpetre. Its chemical properties are apparently identical with those of pilocarpine, although, like the latter, it is not precipitated from watery solutions by chloride of gold. Like pilocarpine it is readily transformed into an amorphous base endowed with physiological properties similar to those of atropine, and which Harnack proposes to designate under the name of jaboridine. As regards physiological action, pilocarpidine appears to closely resemble pilocarpine.—*Gazette Méd. de Paris*, No. 42, 1885.

#### THE ACTIVE CONSTITUENT OF THE ROOT OF BAPTISIA TINCTORIA.

According to VON SCHROEDER (*Pharm. Post*, October, 1885), the active constituents of this root consist,—first, of a glucoside, baptisin, which is insoluble in water, and which acts physiologically, like the indifferent bitter substances; second, a glucoside, baptin, which is soluble in water, from which it crystallizes in microscopic needles; it is a feeble laxa-

tive; third, of an alkaloid, baptitoxine, which is poisonous in small doses. This alkaloid in a frog produced arrest of respiration and then central paralysis. In mammals it causes acceleration of respiration and increase of reflex action. Death follows as a consequence of paralysis of respiration.

#### A HIDDEN DANGER.

The risk of conveying parasitic disease by means of the brushes and combs used in hair-dressing is not an imaginary one. It is no doubt much reduced in the better-class establishments by careful attention to cleanliness of the implements used, but even in them accidents are liable to occur at times from forgetfulness or neglect. A rush of customers cannot always be controlled, and there may not be time in each case to provide against the transference of contagion, which, perhaps, may be exceptional, and, as a rule, unlooked for in the course of a given business. Such unusual circumstances have nevertheless to be considered and dealt with. Some will insist that a good supply of brushes in permanent use, with regular cleansing, is the only reliable guarantee for all emergencies. Against the grounds of this argument nothing can, of course, be said. If the plan is borne out in practice, no ill can come of it. At the same time further suggestions are both admissible and welcome. Among such it may be well to note a method, in favor of which all others have been discarded by a Liverpool operator. This consists in supplying each customer with a separate and personal brush, which is, in ordinary phrase, "given in" with the hair-cutting. The plan appears to pay, and we may readily believe the assurance of its originator, that by its employment the fear of parasitic troubles is reduced to a minimum. A comb is not mentioned as being given along with the brush; but this, again, can be much more easily and rapidly disinfected as required, and practically, we suppose, may be left out of account. Certainly the novel arrangement with regard to brushing is a gain on the side of healthy practice.—*Lancet*, January 2, 1886.

#### A NEW BALSAM.

In the *Archiv der Pharmacie* (November, 1885, p. 817) DR. P. ZIPPERER describes and illustrates the structure of the root of *Paramecia vulneraria*, Radl., which is used by the natives of the Philippine Islands, as well as by

the residents there, to furnish a kind of balsam that possesses remarkable healing properties. This is known by the name of Cebu, or Tagul-away balsam. It is prepared by boiling the bark of the roots and twigs, as well as the leaves, of the plant in cocoanut oil, and forms a yellowish-white oily liquid having a peculiar odor. Dr. Zipperer's examination of the plant shows that it contains 8.5 per cent. caoutchouc in its tissues and three per cent. resin soluble in alcohol, and to these constituents its value appears to be due. Dr. Zipperer states that during two years' residence in the Philippines he had seen the balsam used by European doctors, as well as by the natives, with great success in various skin-diseases and for healing wounds. It appears to promote an unusually rapid cicatrization. The plant is a climber, growing in the mountainous declivities of the island of Cebu, whence it is chiefly obtained.—*Pharm. Journal and Trans.*, November 28, 1885.

#### THE PREVENTION OF BALDNESS.

It has been estimated that one-half the adult men of American birth living in our cities are bald-headed. The estimate is not exaggerated, if it is applied to persons above the age of thirty, and it may be rather under the mark. If, now, it be conceded that one-half of our American business and professional men are bald at the present time, it would be interesting to speculate as to the condition of the heads of their descendants some hundreds of years from now. The probabilities point toward a race of hairless Americans, for baldness is extremely liable to be propagated in the male line, and to appear a little earlier in each generation. The American nation is threatened with the catastrophe of a universal alopecia.

It appears to be worth while, therefore, to consider the subject of prevention, since no means have yet been found for the cure. Why are so many men bald before their time?

The answer has almost always been that it is due to the excessive strain and ceaseless mental and physical activity to which American methods of business and modes of living conduce. From the visitors' gallery of the Stock Exchange, for example, one views a mob of shining pates belonging, as a rule, to rather young men.

Any reformer, however, who expects to prevent baldness by changing American habits may as well stop at once, for he will surely

fail. Now, there may be, perhaps, help in some other quarter. The sons of prematurely bald fathers should bear in mind that if they wish to save their hair it will only be through industrious attention to their scalp. This much-neglected surface should be thoroughly cleansed at certain intervals. It should be carefully and regularly examined, and if it be unhealthy, dry, and scurfy, the proper applications should be made to it. The wearing of unventilated hats is one of the greatest sources of failure of nutrition of the hair, and these must be avoided. The beard never falls out, because it gets plenty of sunlight and air. These are what the hair of the scalp needs, also. Women are less bald than men, because, for one reason, their scalps are better ventilated. In fine, civilization has made the hair-producing organs of the scalp delicate and feeble. They have to be nursed and cared for, or they atrophy and disappear. Young Americans who do not wish to lose their hair before they are forty must begin to look after their scalps before they are twenty. —*New York Med. Record*, January 23, 1886.

#### ICE TO THE SPINE IN OBSTINATE VOMITING.

DR. W. L. DAVIS reports (*Mississippi Valley Med. Monthly*) a case of vomiting in typhoid fever in which every remedy, even pellets of ice, was rejected by the stomach. He applied ice to the lower part of the spine in considerable quantity, and the vomiting instantly ceased; a profuse perspiration followed. The use of ice was only persisted in when indicated; and cool sponging was instituted with marked benefit, so that the ice was only occasionally required. Recovery in the average time took place.

#### SUBCUTANEOUS INJECTIONS OF ATROPINE AND MORPHINE FOR THE PREVENTION OF CHLOROFORM-SYNCOPE.

In 1880, Dastre and Morat, starting with the assumption that the cause of chloroform-syncope was to be found in the action of the chloroform vapor on the pneumogastric, attempted to prevent arrest of the heart during chloroform-narcosis by means of atropine. Acting on this suggestion, AUBERT (*Centrall. f. die Gesamte Ther.*, October, 1885) has employed this method with great success in preventing

syncope in chloroform-narcosis. He employs a solution containing  $\frac{1}{10}$  of a grain of sulphate of atropine and  $1\frac{1}{2}$  grains of the hydrochlorate of morphine in 160 minims of distilled water. On this solution a Pravaz syringe is injected twenty or thirty minutes before the administration of the chloroform. The advantages of this method are claimed to be its safety and the rapid production of anæsthesia, rarely requiring more than two minutes, the absolute rest of the patient, the readiness with which the patient is aroused, and the slowness of the after-effects.

#### INFLAMMABLE COSTUMES.

Several instances of death have recently formed the subject of inquiry, during which it has been elicited that while dressing themselves in the light costumes usually worn at evening parties, the victims of these accidents have been severely burned as a consequence of their flimsy costumes becoming ignited. Often it is a candle held incautiously near the skirts that does the mischief; at other times the unfortunate pleasure-seeker approaches too near the fire, the exceedingly light character of her dress enabling it to be readily drawn to the flame by the natural current towards the chimney, and so leading to its destruction. In all these cases, however, the prime cause of the accident is the highly inflammable nature of the material out of which ball costumes are manufactured; and it is quite clear from the narratives of the painful accidents recorded within the last few days, that but for this circumstance the fatalities would not have happened. It is, therefore, the more essential to urge upon society the great importance of adopting some adequate means of obviating so great a danger to life in the future; and the most simple and effectual plan in this connection seems to be to prepare the dress-material employed in such a way as to ensure its being proof against fire. To this end several methods have been proposed, but we believe that which affords the greatest satisfaction is to steep the muslin or other garment in a solution of tungstate of sodium, whereby it is rendered quite non-inflammable, and may be worn with impunity in dangerous situations. It is much to be desired that the public should be aroused from its apathy in respect to this matter, and show an interest in a question of so much importance to itself.—*Med. Press and Circular*, January 6, 1886.

### NOTE ON PAPAYOTIN.\*

BY A. JACOBI, M.D., NEW YORK,  
President of the New York Academy of Medicine.

THE trunk and fruit of the South American melon-tree, papay-tree (*Carica papaya*), contain a juice which coagulates readily into what Peckalt called papayotin, and a small quantity of serum. The digestive ferment, called papain by Wurtz and Bouchut, papayo-

tin by others, is obtained by treating the juice with alcohol. It digests a thousand or two thousand parts of moistened fibrin, according to others two hundred, when cool or warm. Muscular tissue gets soft in a five per cent. watery solution within half an hour. Pulmonary tissue is not altered in this manner. The living mucous membrane is not changed at all. Very weak solutions have no effect; solutions of one-half of one per cent. are but little effective.

The mucous membrane is so little affected that dogs, cats, and rabbits, which took from 2 to 5 grammes (30 to 75 grains), showed no symptoms, nor any changes in their digestive mucous membranes. But rabbits and dogs died five minutes after a subcutaneous injection of 0.05 to 0.1 gramme (1 to 1½ grains).

\* Read before the Medical Society of the State of New York, February 2, 1886.

The therapeutical administration of papayotin must be based on the following facts: that it is innocuous when taken internally; that it is dangerous when used subcutaneously; and that its injection into the blood paralyzes the heart and nervous system. Griffith Hughes recommended it in several cutaneous eruptions, Bouchut in cutaneous carcinoma, Albrecht for the easier digestion of meat, Tussac against intestinal worms, Rossbach for the purpose of dissolving diphtheritic (croupous) membranes (*Zeitsch. f. Klin. Med.*, vi. H. 6). A brief notice on papain is contained on p. 1135 of that remarkable book, Stillé and Maisch's National Dispensary, third edition, 1884.

During the third "Congress for Internal Medicine" papain was the subject of discussion by Dr. Finkler, of Bonn, and Rossbach, of Jena. They compare its effect with that of pepsin and pancreatin, with this exception, that it will prove effective in smaller quantity and with less water, between the ordinary temperature and 60° C. (140° F.); best, however, in a temperature of 40° C. (104° F.), and in slightly acid, neutral, and alkaline reaction. Thus it is reliable in rectal alimentation, as the solution to be introduced may be allowed to be neutral.

Diphtheritic membranes are dissolved in a few hours, in a few cases after a day only. Temperatures of 104° and 105° would sink to the normal standard after the removal of the membranes. This observation was made by both Finkler and Rossbach, and proves the rapidity of both absorption and elimination of the diphtheritic poison, to which I directed attention in my treatise on diphtheria (1880). Insufficient results were obtained by some preparations. These were found to consist, under the legitimate rules of modern tradesmen and manufacturers, of milk-sugar. From that very cause ill success has attended some of my cases years ago, while others appeared to encourage me in continuing the use of papayotin. For a year or more I lost confidence, until a few months ago I advised the resuming its administration in a number of cases I was called to see. The report of a few brief cases will suffice.

CASE I.—On the evening of December 29, 1885, I saw a patient of Dr. Kremer's, a delicate boy of 11 years. The symptoms of pharyngeal diphtheria, complicated with some glandular cervical swelling, had lasted nearly a week. For three days past there was croup, of not a very urgent character, so that tracheotomy was not indicated for the time being. The pharyngeal

membranes were whitish, solid, and large, covering the tonsils, extending to the edge of the soft palate; the uvula was swollen, and the membranes extended backwards and upwards. The hourly application of papayotin to the throat was recommended. The mixture was 1 of the remedy, 4 of water, and 4 of glycerin; it was continued through the night. The doctor reported to me the almost complete disappearance of the membrane at his next visit, the following morning. As I learned later, the case terminated fatally, after a short improvement, by the gradual increase of the laryngeal obstruction, which necessitated a hurried tracheotomy, and resulted in death a few days after the operation.

CASE II.—In the early hour of the afternoon of January 1, 1886, I was called to see a patient of Dr. Hubbard, a boy 1 year and 6 months old, suffering from croup. There was hoarseness, long-drawn inspiration, some supraclavicular and infraclavicular and epigastric recession,—that is, the symptoms of laryngeal stenosis. There was no membrane in the mouth or throat, and but little congestion of the fauces. There was no fever (the temperature being taken, as I always do, in the rectum), and therefore the diagnosis was membranous laryngitis. The indication for tracheotomy was not urgent, and the operation postponed. Meanwhile,  $\frac{1}{4}$  of a grain of corrosive sublimate was ordered every half-hour for the first six or eight hours in considerable dilution, and the temperature and the moisture of the air in the room regulated as I found them before. Dyspnoea increased more rapidly than we expected, and tracheotomy was performed at 8 P.M. The general treatment was continued. No untoward symptoms showed themselves until the third day, then the temperature rose somewhat, the respiration lost its normal character, the occasional moist râles disappeared, respiration became more dry and sawing, indicating the progress downwards, into the trachea and bronchi, of pseudo-membrane. There was a slightly cyanotic hue on the upper lip. The internal and dietetic treatment was not changed, and papayotin was used in 4 parts of water and 4 parts of glycerin in such a manner that the feather from a live pigeon's wing was dipped into the liquid, at first every hour, later on every two hours, and introduced through the hard rubber tube way down into the trachea and below, and turned round several times for the purpose of leaving the medicine inside. After a few hours shreds of membrane were coughed up. The treatment

was continued through some days. More membranes came; gradually they became softer and macerated, and finally the secretion became muco-purulent and mucous. Before the end of the second week the tube was removed.

CASE III.—H. B., æt. 15; France; resident New York City; seen in consultation, January 19, 1886, with Dr. Heinemann. Patient had been ill for three days. Had severe nasal and tonsillar diphtheria.

*Treatment.*—Tr. ferri potas. mixt.; local tr. ferri applications; bichloride and acid. bor. spray, and douché for nares; supporting treatment.

Within five days the nares were freed. The tonsils improved considerably, but at the end of three days the improvement in tonsils remained almost stationary. A fair amount of glandular swelling about the angles of the lower maxilla.

My recommendation to use papayotin, i; aq. and glycerin., aa ii, mixture, and apply it freely with the brush, was now resorted to.

Dr. Heinemann reports as follows: The papayotin was applied every hour. Within six hours the membrane presented a translucency, having been melted down to some extent. Within twelve hours the effect was decided, portions of the thin membrane coming away upon the brush without effort. Gradually the membrane seemed to be dissolved, and at the end of thirty-six hours it had disappeared. Only at a few points of ulceration did an eschar remain for some days longer.

CASE IV.—J. L. O., æt. 38; dentist; United States; seen in consultation May 15, 1885. Patient was under the care of Dr. H. N. Heinemann. On April 16, 1885, patient became ill with tonsillar diphtheria. Subsequently it extended to the nares.

The treatment consisted in the iron and potass. mixt. internally, local application of tr. ferri chlor. and glyc., spray of bichloride sol. and acid. bor., and douche for nose. Supporting treatment in addition as usual.

Despite careful attention for four weeks the membrane came and went, the pharynx, soft palate, and tonsils clearing, and then again being recoated, one spot after another infecting and reinfecting the neighborhood.

On May 15, 1885, I recommended, upon consultation, the use of papayotin as a local application.

Dr. Heinemann reported to me as follows: "The membrane melted down under its use rapidly, and within forty-eight hours had completely disappeared."

# *PISCIDIA ERYTHRINA IN THE TREATMENT OF CONVULSIVE AFFECTIONS.*

By S. A. NEWHALL, M.D., NEWTON, KANSAS.

ON January 9, 1886, I was called in haste to the bedside of Mrs. S., aged about 30 years; a tall brunette; married for four years, but has had no children. She has been subject to attacks of local congestion, oftenest in uterus or ovaries, occasionally in lungs, or stomach and bowels. She had complained all day of pain in the muscles of the body and limbs, and very frequent, severe pains in the head; but she refused to have me called until about eight o'clock in the evening, when she became wildly delirious. I found the patient in bed, manicac, with staring eyes, with violent spasmodic contraction of the flexor muscles of the hands and feet, constantly begging for water, drinking all she could get, and yet with no relief. The pulse was regular, but rather full, about eighty beats to the minute, the temperature normal, as nearly as I could judge, as I could not keep her quiet long enough to use the thermometer. The spasms became constantly stronger, until they extended to the spinal muscles, producing the most violent opisthotonos I ever witnessed. At ten o'clock the tonic spasms were so violent that she stood upon the top of her head and her feet in bed in a perfect semicircle, requiring four strong men to hold her and prevent her injuring herself. These spasms succeeded one another in rapid succession, with only a moment's interval, accompanied with gnashing of the teeth, and at times frothing at the mouth, and when given water or medicine from a spoon she would snap the spoon or clutch it between the teeth, and at times the jaws were firmly set in tetanus.

I had watched the history of piscidia erythrina since its first introduction, and, from its action upon the cerebro-spinal nervous system and its anodyne effects, I decided to give it a trial, and sent to the druggist for two ounces; I gave 40 drops at 10 o'clock P.M., and in fifteen minutes was rejoiced to see its modifying effect upon the spinal muscles, and, in fact, upon the whole muscular system; the spasms became much less frequent and of shorter duration.

I repeated the dose in an hour, with increased and marked improvement, and at midnight gave the third dose, which began to show its irritating effect upon the stomach; but, in half an hour after the third dose, had the satisfaction of seeing my patient drop into a quiet sleep for a few minutes, and

awake rational and free from spasm. I left direction if the spasms returned in any degree to repeat the dose, but none was required until the next day, when they returned at about 2 o'clock P.M., when she was given 40 drops of piscidia, which produced such violent irritation of the stomach that she could not retain it. I was called at 7 P.M. to find her in violent spasms again, but not so frequent. I found it impossible to administer the piscidia by the mouth, and gave by enema one teaspoonful of the fluid extract and the same amount of hot water, repeating the dose every hour for three doses as before, with the same effect in arresting the spasmodic action and relieving all pain. The next day I directed one teaspoonful by enema at 2 and 4 o'clock P.M. This treatment was all that was required, and my patient was perfectly cured, and was attending to light household duties in three days from the last spasm.

In the THERAPEUTIC GAZETTE, vol. viii. page 331, is a careful study of the drug by George W. Winterburn, Ph.D., M.D., of New York, giving a clear guide to its physiological action, as well as to its therapeutic uses. Its anodyne effect is doubtless owing to the paralyzing effect upon the nerves of sensation, and its antispasmodic action is owing to the same paralyzing effect upon the motor nerves. There was a distinctly perceptible flushing of the face, with slight diaphoresis after the second and third doses, which I attribute to its relaxing effect upon the capillaries, and, consequently, prompt relief of the congestion, very similar to the relief produced by veratrum viride in pneumonia or pulmonary congestion.

ON THE NUTRITIVE VALUE OF SOME  
BEEF EXTRACTS—AN EXPERI-  
MENTAL INQUIRY.\*

BY THOS. J. MAYS, M.D.

**D**URING the last seven months my leisure time has been principally employed in efforts to determine the nutritive value of some of our principal beef preparations, and I beg your brief attention this evening for the purpose of bringing the results of these researches before you.

That there is no idea so erroneous as to be wholly devoid of truth, nor one so true as to be wholly devoid of error, is an ancient maxim, and its truth is probably as well illustrated in

the prevailing ideas of the nutritive value of the beef extracts as it is in anything else. A study of the extensive literature of the beef extracts shows the inconstant and indefinite opinions which have been held concerning their action, and also illustrates the fluctuations of thought which the medical profession is liable to undergo. Liebig, who was one of the first to invest this question with scientific interest, held no less than three different theories regarding their action during the last twenty years of his life. In his "Letters on Chemistry," published in 1851, he distinctly rates the beef extracts as nutriments, —*i.e.*, as substances which are capable of supplying working force to the muscles of the body. In Auerbach's "Volkskalender," page 148, published in 1868, and in his "Chemische Briefe," issued in 1865, he expresses the opinion that they are merely condiments (*genussmittel*), and hence only act as stimulants to the process of digestion and to the general nutrition of the body. Later he conceived the idea that they are nutrients not only in the sense of supplying force to the body, but as furnishing material wherewith the bodily tissues are constructed. Since his death, however, medical opinion has by almost universal consent reverted to the second idea entertained by him, viz., that the beef extracts are of no or very little value as foods. It is true that this has been questioned by some whose clinical observations have led them to different conclusions, yet I do not know of a single work on physiology, therapeutics, or pharmacology that does not assign the beef extracts among the non-nutritious alimentary agents. Probably the most positive expression of this feeling among those who are considered modern authority on such subjects is that of Dr. Fothergill, in his "Handbook of Treatment, or Principles of Therapeutics," who, on page 537, says that, "as a food, beef-tea ranks low. It contains meat-salts, a small quantity of albumen, and a little gelatine, together with some advanced nitrogenized matters useless in histogenesis. But there is little in it to repair tissues, and less in it to sustain life, so far as our knowledge yet extends. There is little real force-bearing material in the protean compounds of beef-tea. For the starving fever-patient, to give him beef-tea alone is almost to give him a stone when he asks for bread. It makes him feel better for the time being, but that is due to its stimulant properties."

There can be no doubt that the cause of the prevailing scepticism concerning the nu-

\* Read before the College of Physicians of Philadelphia, February 3, 1886.

tritive value of beef extracts is largely due to the experiments which were made by feeding animals exclusively on these preparations, with the result that all of them died within a short period of time. Indeed, Kemmerich affirms that they died more quickly than those which were left to starve from hunger. This has the semblance of proof that beef extracts are not capable of supporting life. Sober reflection teaches, however, that no animal can subsist continuously on any single food, and that such a test would unceremoniously refute the food value of any substance, no matter how nutritive it might be. But, beset with difficulties as this investigation evidently is, the question is not whether these substances are capable of sustaining life alone, but whether it can be shown that they contain any nutritive value at all, and, if so, how much. Here everything depends on the method which is employed to determine this question. It is imperative that this should be definite and exact. It must be able to show the functional state and condition of the organism before, during, and after the addition of these substances; or, in other words, it must demonstrate whether the organism is or is not capable of performing work when these substances are added to it.

To meet all these desiderata I selected the isolated frog's heart, which has already proved itself so pregnant with good results in the hands of Ludwig, Cyon, Kronecker, Bowditch, and others, in the full belief that it will show itself as capable here as it has in clearing up other problems in experimental physiology. Only quite recently Professor Yeo (*Journal of Physiology*, vol. vi. No. 3, p. 93) has succeeded in demonstrating with it the reduction of oxyhæmoglobin, a phenomenon the existence of which was assumed but never proven by direct observation.

The experiences of Professor Kronecker, Drs. Martius, McGuire, Von Ott, and others, show very clearly that when the frog's heart is well washed out with a 0.6 per cent. saline solution, and then allowed to beat with the same, its pulsations gradually get less in force and in elevation, until at last, in the course of an hour or two, it becomes entirely exhausted, and is unable to work any longer. But when this stage of complete fatigue is reached, and the heart is filled with blood or serum, it recommences to beat, and its pulsations gradually gather in strength and in elevation until their former altitude is attained. If, instead with blood, the heart were refilled with the saline or any alkaline, acid,

or even alkaloid solution, it would never show any sign of returning vitality. This observation means that the saline, alkaline, acid, and alkaloid solutions are devoid of material with which the heart can perform its function; and although it works while it is filled with these solutions, it does so at the expense of the nutritive material stored up in its own meshes, and not with any energy derived from these solutions. Indeed, Dr. Pohl-Pincus (see *Verhandlungen der Berliner Physiologischen Gesellschaft*, February 23, 1883) has brought forward evidence which indicates that in the wall of the frog's heart there exist lacunæ (nahrspalten) designed for the purpose of storing up nutritive material. As soon as this stored-up supply is exhausted it ceases to beat, and any solution which is now applied to it with a view to re-establish its pulsations must contain some elements which are capable of nourishing it. These essentials are found in the blood and serum of most animals. Dr. Von Ott (*Archiv. für Physiologie*, March, 1883) has also shown that milk has the power of nourishing the heart. And Professor Ringer (*Journal of Physiology*, vol. vi. No. 6), in following the same line of inquiry, found that both albumen and gelatine are capable of sustaining the heart's contraction. In my own work on the nutritive value of different concentrations of blood, performed in the Berlin Physiological Laboratory under the direction of Professor Kronecker (*pub. Verhandlungen der Berliner Physiologischen Gesellschaft*, January, 1883), I found that the amount of work of the frog's heart performed with blood depends entirely on the degree of dilution of the latter agent. Dr. McGuire found, however, that 1 to 3—i.e., one part of blood to three parts of saline solution—gave the best results.

In summing up the literature of the action of the frog's heart in its relation to our subject, we find the following: That the heart in performing work consumes oxygen; that after it is once completely exhausted it cannot resume its pulsations unless food-energy is supplied to it from the outside; that blood, serum, milk, albumen, and gelatine are capable of acting as foods and of restoring its power of contraction, but no other substances have heretofore been shown to possess this property; that the pulse-elevations and the amount of work which the heart is able to do depend in a great measure on the degree of concentration of the food. These data, moreover, demonstrate very fully that the heart does not exercise the function of a

purely circulatory organ in these experiments, but that it is an organic medium possessed of the power of assimilation, of transformation of energy, of contraction, and of respiration.

The apparatus which was employed in testing the food value of the beef extracts was the following: The heart, by means of a double cannula, on which it is securely but gently tied, is attached to a Kronecker-Bowditch heart-apparatus, and then through a mercury manometer and an appropriate glass needle it records its pulsations upon a revolving cylinder. The heart is fed or transfused through the double cannula from two Mariotte's bottles with any desirable fluid, and, in order to keep it pulsating regularly, minimum shocks of one Daniell's cell through a Du Bois sliding induction-coil were employed about every four seconds. Before testing the beef extracts the heart was in every instance well washed out with a 0.6 per cent. saline solution, after which it was allowed to work with the same until all its stored-up material was exhausted and its pulsations reduced to zero. Then a weak solution of the inorganic elements of the beef extracts, chiefly containing phosphate and carbonate of potassium and chloride of sodium, was carefully tested on the heart to find out whether it had any power to induce cardiac contractions, but it failed in every instance. The same was also found to be true of a solution of urea whenever it was tried. After this preliminary work a number of different dilutions of a beef extract previously prepared with a 0.6 per cent. saline solution (usually in the following proportions—1 to 100, 1 to 250, 1 to 500, 1 to 666, 1 to 1000, 1 to 2000, 1 to 4000) were alternately introduced into the heart and their effects noted. The stronger dilutions, like 1 to 100 to 1 to 500, had no influence whatever in restoring cardiac contractions; but in every specimen which was examined the dilutions from 1 to 666 to 1 to 2000 had the power of reviving and of maintaining the beats of the heart, as the following traces given by Valentine's Meat Juice clearly show:

#### EXPLANATION OF THE TRACINGS.

(To be read from top to bottom, and from left to right.)

(a) Heart filled with 0.6 per cent. saline solution; (b) refilled with same; (c) refilled with same; (d) filled with phosphate of potassium solution, 1 to 1000; (e) filled with saline solution; (f) filled with Valentine's Meat Juice, 1 to 1000; (g) refilled with same; (h) filled with phosphate of potassium solution, 1 to 1000; (i) filled with saline solution; (j) filled with Valentine's Meat Juice, 1 to 1000; (k) refilled with same.

In this experiment the heart was filled with a 0.6 per cent. saline solution (a), and allowed to work with it until it was fatigued; at (b) and (c) this was repeated, and the pulse-elevations grew after each filling, not because the saline solution conveyed any nutriment to the heart, but because it had not consumed all the energy stored up in its walls. At (d) and (e) neither the phosphate of potassium nor the saline solution could revive the heart, showing that its whole store of energy was exhausted. At (f) and (g) Valentine's Meat Juice was introduced, and the pulsations grew to about half their original height. The other beef preparations which were examined in the same manner as Valentine's Meat Juice were Reed & Carnrick's Beef Peptonoids, Parke, Davis & Co.'s Sarco-Peptones, Johnston's Fluid Beef, Cibil's and Liebig's Extracts, besides milk, and all gave evidence that they possessed nutritive properties. Although the amount of nutrition varies somewhat in each specimen, as will appear later on, every one gave tracings substantially similar to those given by Valentine's Meat Juice.

Judging from these data, I think the following deductions can be made concerning the influence of the beef extracts on the frog's heart:

1. That they are absorbed and assimilated.
2. That they contain material which has the power of inducing muscular contraction, a power which has heretofore only been shown experimentally to exist in the higher animal albumens or proteids.
3. That hence, whatever else they may be, they are nutrients in the full implication of that term.

After it was thus demonstrated that these beef preparations contained definite nutritive properties, it was deemed desirable to ascertain the value of each, and means to this end were instituted by comparing their effects with those of a two per cent. solution of dried bullock's blood alternately on the frog's heart in the following manner: In the first place, the heart, after being washed out, was filled with the two per cent. blood solution, and then allowed to beat until its pulsations were reduced to a minimum, or until the whole nutritive supply of the blood solution was consumed, after which it was washed out again and filled with a solution of the beef preparation to be tested, and allowed to beat with it until its pulsations were again reduced to a minimum. A large number of comparative tests were made of each of the above-named beef preparations in this way, and the

following products were obtained, which indicate the mean percentage of the number of pulse-beats given by each preparation, while that of blood is taken as 100. These figures are probably not absolutely true, but they give an approximate idea of the nutritive worth of these extracts when compared with that of a two\* per cent. blood solution, which is capable of producing a normal cardiac contraction.

	Mean Percentage of Number of Pulse-beats.
Liebig's Extract of Beef.....	58
Johnston's Fluid Beef.....	59
Valentine's Meat Juice.....	60
Cibil's Extract of Beef.....	61
Sarco-Peptones (Parke, Davis & Co.)	62
Beef Peptonoids (Reed & Carnrick)..	74
Milk.....	100
Two per cent. solution of dried bullock's blood.....	100

From this table it appears that all these preparations contain very nearly the same amount of nutritive material except the Beef Peptonoids, which contain from ten to fifteen per cent. more than the others. It must not be forgotten in this estimation that the Beef Peptonoids are not a pure beef extract like the rest, but a compound of the latter with milk and gluten. Therefore, in order to get at the true value of this preparation, it is important to test each ingredient. Milk alone gives as good results as the blood solution, as can be seen from the table, and there is no doubt that a portion of its valuable property is due to this agent.

The next question which arises in this investigation is as to which of the many organic bodies resident in the beef extracts this nutritive property is due; and I must confess that, principally owing to the difficulty of obtaining these organic extractives, this portion of the work remains incomplete, but I am making preparations to resume it at an early day. It can be safely stated, however, that the inorganic elements of the beef extracts contribute no share to this result, for the phosphate of potassium solution contains all these, and in every instance where this was tested it failed to bring out the least cardiac reaction. Hence these can be left out of consideration.

When finely-divided beef muscle is exposed to the action of about four or five times its own weight of cold water for four or five hours, and then well pressed out, it loses from sixteen to twenty-four per cent. of its original

weight. In this watery solution is contained from two to fourteen per cent. of flesh albumen, while the remainder is made up of kreatin, kreatinin, sarkosin, sarkin, xanthin, carnin, inosit, fat, glycogen, and the inorganic elements, while in the residue there is left nothing but fibrous tissue, principally composed of muscular fibres and connective tissue, which is tasteless, rejected by animals, and entirely unfit for nutrition. Therefore, it is very probable that all the nutritive element of beef muscle resides in its organic extractives.

Now, there cannot be the least doubt that the variable amount of albumen contained in the beef extracts furnishes some of the nutritive property displayed by them, but it is far from my intention to claim that this is exclusively due to it. Indeed, I have found altogether unexpected indications during the investigation which may on further examination throw some more light on this question. One thing, however, remains steadfast throughout, and that is, if the albumen of flesh is not the sole nutritive element in these beef preparations, then some or all of the organic bodies which they contain must be nutritious, and can no longer be regarded as effete products of the animal body.

It is not necessary to point out, then, that the multitudinous composition of these extracts makes them a very valuable class of alimentary substances, both for nutritive and constructive purposes; and before closing this interesting subject let me refer very briefly to the practicability of the subcutaneous introduction of these agents. I think it is quite evident now that these preparations are assimilated and utilized by the frog's heart without previously passing through a digestive process, and we have no reason for believing that this does not also obtain in the human organism; hence, in conditions where the stomach has an intolerance of food, or where there is any hindrance to the introduction of the same through the primary passages, the object of feeding the patient can readily be secured by introducing a suitable preparation hypodermically. A number of years ago I treated several such patients with Valentine's Meat Juice, which, on account of its complete solution in the normal state, is probably preferable for this purpose. I injected from fifteen to twenty minims three times a day with good effects. I failed, however, to keep a record of these cases, but recollect that one was a case of persistent vomiting caused by a severe blow on the head, and that after each

\* Two per cent. solution of dried bullock's blood gives as good cardiac contractions as fresh blood, in proportion of 1 to 3.

injection the patient expressed himself as being stronger and feeling as if he had eaten something. Not the least irritation was produced at the point of injection, and I think this field deserves further investigation.

In conclusion, I wish to thank Dr. Marshall, of the University of Pennsylvania, and Dr. Leffman, of Jefferson Medical College, for valuable aid in prosecuting these researches.

*CASE OF PERFORATING ULCER OF THE STOMACH, WITH REMARKS.*

By H. C. WOOD, M.D.

THE following case has seemed to me worthy of a brief record on account of the difficulties of the diagnosis and of the therapeutic lesson to be drawn from it.

I was recently called, about eleven o'clock in the morning, by a most urgent summons to see a patient. On going to the house, was told that the patient had enjoyed throughout life extraordinarily good health; had never been sick; at all times remarkably free from the pains which seem to belong to her sex; had been accustomed to take enormously long walks without suffering; to run up and down stairs freely; and in every way to be extremely active. The only physical annoyance which she had ever had was from occasional sour stomach and mild dyspeptic symptoms. On the evening before my visit she had been out; in the morning had taken her breakfast as usual; went up-stairs for something, and suddenly cried out for help, stating that she had a frightful pain in her abdomen. I found a woman about 40 years of age, large, robust, but somewhat pallid-looking, evidently suffering intensely. The abdomen was very slightly tympanitic, was distinctly tender over the whole of it, but without any localized spots of excessive tenderness. The pain was over the whole abdomen, but was especially referred for its focus to the left iliac fossa. There had been no sick stomach. I was told that Dr. — was the family physician, and had prescribed for the lady the day before some soda-mint or similar palliative for sour stomach, and I was asked to take charge until his arrival. Morphine was administered hypodermically, and I returned about an hour later. At this visit I noted that the face of the patient had changed entirely. At the first visit it was simply that of a person suffering pain. It had now taken the expression which Dr. J. Forsyth Meigs used to call a decomposed face,— was distinctly what I suppose is meant by the

Hippocratic face. It had the expression which I have learned means a mortal illness. The abdominal tenderness now was very markedly less, and there was much pain in the right shoulder. More morphine was administered. In the course of a few minutes the pain in the shoulder became more intense, whilst that in the abdomen grew less. About half-past one o'clock the condition was as follows:

Abdomen only slightly tender, with but little pain in it. In the upper portion and right shoulder there was such a severe pain that Miss — begged that we might relieve her or that she might die. The pulse was rapid and small, feeble but not irregular; the temperature was not taken with the thermometer, but was below rather than above normal. The pain in the shoulder was increased very greatly on movement, so that it was impossible to raise the patient up; it did not, however, radiate down the arm. Auscultation revealed a distinct systolic mitral murmur of a soft character.

I was completely at a loss in making the diagnosis. The shifting character of the pain and the excessive violence of the paroxysms, which were provoked by attempted movements, of course led me to the supposition of a violent rheumatic attack, which did not, however, account for the Hippocratic face. The heart-murmur led to the suspicion that the rheumatic inflammation was attacking that organ, but it seemed to me impossible that there should be a rheumatic myocardiac inflammation sufficient to produce a murmur and the facial evidences of fatal illness without irregularity in the heart's action. On returning shortly after this I was told by a servant that the family physician had arrived and my services were no longer needed.

Since the death of the patient, this gentleman, who is one of the most skilful practitioners in Philadelphia, has written me as follows:

"On my first seeing her during the attack I found the pupils slightly contracted, showing the action of the morphine you had administered. I examined the abdomen. It was not particularly sensitive to pressure. I suppose the peritonitis had hardly begun. She complained more of the sensitive surface where the mustard-plaster had been. I felt the hard mass in the abdomen about the umbilicus. It was insensitive, and, having no suspicion of uterine disease, supposed it fecal matter rendered more prominent by spasm of the bowel. While sitting by her she was seized with agonizing pain in the left shoul-

der, which inhibited the heart-beat for several seconds. An effort of movement sent it to the region of the left quadratus, and on raising her from the pillow the erector-spina became rigid, and again in laying her down, just as in lumbago. This shifting muscular spasm led me to the conclusion that the pain was rheumatic in type.

"The following morning a second time I was sent for in haste early, about eight o'clock, but found the patient dead. The family said that during the night she had suffered no pain, but was very restless; that in the morning she complained of feeling excessively weak and cold, and that a cup of coffee was given her, which she said 'warmed her and made her feel much better'; and that almost immediately after that the change came suddenly.

"At the autopsy, a fibroid tumor of the uterus about four or five inches in diameter was revealed. There was also chronic thickening and hardening of the mitral valve, which accounted for the murmur heard during life. Two gastric ulcers were found, one situated upon the anterior, and the other the posterior wall of the stomach, about the middle, and nearly but not absolutely symmetrical; the anterior ulcer was the larger of the two and had perforated the walls of the stomach, making a circular, punched-out opening about one-third of an inch in diameter. The appearance of the edge of these ulcers suggested that they were of old date."

The lessons to be drawn from this case are several.

The existence of so much chronic disease without its being suspected is remarkable. There is an extraordinary difference in what may be called the pain-reactions of people. In some the slightest functional disorder produces an overwhelming amount of pain; in others the gravest lesions may occur with little or no suffering. There seem to have been no uterine symptoms; at least none were ever spoken of by the woman which should have directed the attention to the uterus. One fact which I have not mentioned in the account of the case, of which only since the death I have been told by her family, is that the patient suffered from repeated nose-bleedings. This might, if reported to the physician, have directed his attention to her heart; for, in my own experience, this symptom is very often connected with unsuspected cardiac disease.

The dyspeptic symptoms appeared never to have been violent. The doctor writes me that he had never seen her with any difficulty

which a little bismuth and soda did not relieve in the course of a few days.

According to the statistics of Welch, in about five per cent. of all the autopsies made in Europe either open ulcers or gastric cicatrices are found. It is believed by most authorities that ulcers of the stomach are much more frequent in Europe than in this country; but I cannot help suspecting that at least one reason why gastric cicatrices are less frequently found in the United States is that they are less carefully sought for. It is only a few days ago that I was called in consultation to see a lady about sixty years of age, supposed to be in perfect health, but suddenly attacked with repeated hæmatemesis, which almost proved fatal, due without doubt to gastric ulcer. The physician attached to the coroner's office in Philadelphia informs me that he has had three autopsies on cases of sudden death from gastric ulcer within the last year,—two from perforation, one from hemorrhage,—in which cases there had been no previous suspicion of disease. When, along with dyspeptic symptoms, any local tenderness is found localized in the epigastrium, or a frequent pain in the back even as high up as the shoulders or as low down as the lumbar region, treatment for gastric ulcer should be instituted, unless some other explanation of the symptoms can be made out.

A very curious and at present hardly explicable symptom in these cases of gastric ulcer is the fact that the seat of the pain is not the seat of the lesion. These distant pains, which, for the lack of a better name, may be called reflex pains, seem to be especially felt in abdominal diseases. The frequent association of pain in the right shoulder with disease of the liver is well known, and the records of perforation of the stomach show that pain in the left shoulder is present in a very large proportion of the cases.

In Miss —, the shifting of the pain over the abdominal region to the extreme upper part of the shoulder was very remarkable, and especially was the occurrence of violent spasm noteworthy; indeed, this latter suggests that possibly there was a slight, deep-seated spasm of the muscles during each paroxysm of pain, and that, therefore, the attack was to be considered a reflex cramp. Tenderness in the abdomen, in the case of Miss —, undoubtedly lessened and almost disappeared after the first hour of her attack; this, too, at a time when the shoulder pain was steadily increasing in ferocity. In the latter stages of her disease pain ceased almost en-

tirely. The explanation of this seems to be paralysis by shock, causing excessive peripheral irritation of the nervous centre.

It is probable that the immediate cause of death was the taking of the cup of coffee, and a sudden irritation of the abdominal nerve-fibres and inhibitory arrest of the heart.

In a case like the present the diagnosis during life could hardly have been sufficiently positive to have warranted active treatment; but supposing there had been symptoms previously pointing towards ulcer of the stomach, such as known localized tenderness, vomiting of blood, etc., the question would naturally arise as to the propriety of surgical interference. With a breakfast inside of the abdomen, but outside of the stomach, the patient undoubtedly had no possibility of recovery through the unaided efforts of nature.

Although I do not know that it has ever before even been suggested, much less done, it seems to me clear that, with the results of modern antiseptic surgery before us, we ought, in a case of sudden perforation and escape of the contents of the stomach freely into the abdomen, to open the abdomen thoroughly, wash out the whole cavity, pare the edges of the gastric ulcer and sew them up, or bring them to the front, so as to create a gastric fistula and close up the wound. Of course the chances would be greatly against the living of the patient; but without such operative procedure death is inevitable.

*SOME RARE FORMS OF TINNITUS AURIUM,  
OR NOISES IN THE EARS, SUBJECTIVE  
AND OBJECTIVE.*

BY LAURENCE TURNBULL, M.D., Ph.G.\*

SUBJECTIVE AND OBJECTIVE TINNITUS  
AURIUM.

MRS. F. A. L., aged 47; suffering with tormenting noises in her ears for eleven months; applied April 16, 1884, to me for treatment; left ear affected with painful ear-ache some time before. On examination, hearing-distance was normal; tuning-fork heard in air; meatus dry and irritable; no discharge; no pain; tinnitus aurium of every variety of sound imaginable, all of which were subjective. The right membrana tympani slightly sunken, and very small reflex; the left Eustachian tube more obstructed than the right; the nasal passages were irritable,

and the right enlarged, hypertrophied, and congested; throat and tonsils were inflamed, with slight naso-pharyngeal catarrh. She had no hereditation, but her constitution was not strong. She was greatly prostrated, had fissure of the rectum, and hemorrhoids which had been operated upon, together with functional disease of the heart.

*Treatment.*—For the local affection, she was directed to use boro-glyceride to the ears and nose; the hypertrophied tissue I removed by cutting. She was also directed mountain air, from which she derived great benefit during the summer.

February 27, 1885, she reports noises much less loud and less persistent; has "short intervals of peace," but any mental or physical cause which lowers her system tends to increase the tinnitus aurium.

CHIRPING OF SPARROWS AND MUSICAL  
SOUNDS.

Mrs. M. T., aged 62; a lady of great musical talents, who suffered in girlhood from a severe and protracted attack of scarlet fever, and a second attack later, which left her with a discharge from the nose for a long period, yet she had a remarkable contralto voice. Later in life she had a series of colds in her head and throat which terminated in a sunken drum-membrane and opacity, with deafness. Within the last six months of 1884 she was also attacked with dizziness (vertigo) on rising from her bed, and was annoyed by the chirping of sparrows and a certain musical note, which occurred during the night. She would inform her husband in the night that she heard them, and inquire if he did not also hear them. I placed her upon a mixture of sherry wine and tincture of nux vomica, in tablespoonful doses after meals, feeling sure it depended upon some reflex irritation of the spine to her semi-circular canals. The success of the treatment confirmed the diagnosis. The use of this drug entirely relieved the annoying symptoms after one month's treatment.

PULSATING NOISES, WITH VERTIGO.

Miss Maria C., the sister of a distinguished Western physician, was sent to the writer with a letter, in which he stated that his sister had a persistent discharge from the right ear, and was almost absolutely deaf in that ear. She was a teacher of music, and had to be much exposed out of doors during all kinds of weather. She was very intelligent and cultivated, and was a skilled musician, but was

\* Aural Surgeon to Jefferson Medical College Hospital.

much more distressed about the discharge and odor, which was obvious in spite of her great care. She was also much annoyed by the peculiar pulsating noises in that ear, and the dizziness was also so severe at times that she was afraid of falling, and had to grasp at any object for support. She had been treated by various means, but without success. Having been very successful in my treatment with a nephew, she placed herself under my care, being ready to carry out my directions faithfully. After cleansing the ear, I found the membrana tympani perforated, the opening in the upper quadrant, but being entirely covered with polypoid granulations which extended from the perforation all the way forward, involving the upper wall of the bony meatus. After removing the posterior mass by several operations, by the wire snare, pressure was made by a probe, and it entered into a cloaca or opening of diseased bone, and this at once caused her a severe attack of vertigo, which lasted, even when the instrument was removed, for several seconds.

By the administration of large doses of quinine and hydrobromic acid, and now and then an anodyne on account of pain in the part, she was able to allow me gradually to remove all the diseased bone by scraping with a small sharp, spoonlike instrument. I then applied the actual cautery, and, lastly, a ball of fused nitrate of silver on an aluminium wire. After many months of treatment it filled up with healthy granulations, and closed. The discharge gradually diminished, and the perforations healed by the use of boracic acid and solution of boro-glyceride. Several relapses occurred, but now—June, 1885—she is well. She has been residing in the country, giving music lessons and doing Sunday-school work, and being out in all weather, has had no severe relapse.

#### SPASTIC CONTRACTION OF THE INTRINSIC MUSCLES OF THE EUSTACHIAN TUBE.

Mrs. William R. B., 25 years of age, a lady of wealth and cultivation, was sent by her physician, January 26, 1883, to me on account of annoying sounds in her ear (the right), which she described like the buzzing of a large fly, which she not only hears but her friends also. The hearing-distance is normal; tuning-fork heard in air; has never had any discharge from the ear, and has no pain, but the noises are distressing and disturbing; the membrana tympani of the left side normal; Eustachian tube open, but containing mucus; has had no vertigo; throat and tonsils divided

up into separate layers; sensitive mucous membrane, somewhat congested, and secreting an abundant tenacious mucus. The disease first noticed January 19, 1883; no hereditary; constitution delicate, not strong; has suffered from measles and scarlet fever.

In this case the crackling sound was caused by the clonic spasm, or irregular contraction of the muscles of the ear or Eustachian tube, which sounded like the irregular ticking of a watch a distance off. The sound could not be suppressed by any effort of the will. At every sound a corresponding contraction could be perceived in the velum palati. The noises would not stop when the velum palati was raised by an instrument.

*Diagnosis.*—Spastic contraction of the tensor tympani causing the noise in separating the mucus in the Eustachian tubes.

*Treatment.*—Having been under the care of two medical gentlemen,—one a general practitioner, and the other an ophthalmic surgeon, who had employed various internal remedies, also Politzer's air-douche, balm tranquille, etc.,—I directed inhalations of chloroform, and belladonna by the middle ear, to allay spasms, and valerianate of quinine and oleo-resin of cubebs to act upon the nervous system and mucous membrane and the Eustachian tube. I also employed the primary galvanic current in front of the ear and in the Eustachian tube by an intertympanic catheter, and this, together with the local application of a sol. argenti nitratis to the tonsil, diminished the sounds somewhat.

January 31. States she is a little better; the sounds come and go now; battery continued, also medicine.

February 7. Very much improved, but finds the medicine nauseates her. She was directed to reduce the dose. Continued the use of the battery, with the local application to the throat and near the Eustachian tubes of the fluid extract of hydrastis Canadensis by means of my Eustachian forceps.

February 15. Has had no return of noises since her last visit, but has had a distinct crackling noise different from the other, and only heard by herself, showing a change in the condition of the Eustachian tube and the muscular apparatus. She continued to improve, and finally the noises left her. I met her several times, and the cure remained permanent.

I have treated a number of these cases, and they may be arranged under two classes,—one in which the spasm is involuntary, and not controlled by the will of the patient, and

another class, of a true nervous or hysterical order, in which the patient is able to produce them at will, and can prevent them. The simple enlargement of the tonsils is not sufficient of itself to cause it, nor mucus in the Eustachian tube, else the cases would be more numerous. The reflex irritation is extended so as to cause spasm of the tensor tympani or stapedius; but the larger number of observers, of which I am one, believe that it also involves the palatine muscles, in which the anterior wall of the mouth of the Eustachian tube is suddenly drawn away from the posterior.

#### RHEUMATIC OTITIS MEDIA, WITH TINNITUS AURIUM.

Mrs. H. G., aged 55 years, February 19, 1883, applied to me for treatment. Both ears affected, caused by a fall two years before; hearing-distance normal; tuning-fork heard in air; no discharge; occasional pain in the left ear; a roaring sound in the right and a singing in the left; both membrana tympani slightly opaque, the left more than the right; Eustachian tubes open; vertigo on stooping down and rising; throat and tonsils irritable; no hereditation, and health and constitution good, but suffers from constipation. She was directed pilulæ hydr., gr. iii; ext. hyoscyami and colócynth. comp., aa gr. i.  $\mathfrak{r}$ . Ft. massa pilulæ No. 1. S. One pill at bedtime every night.

February 27. No improvement; most pain at night, and fulness over the liver and pain in the back of the head and in the chest; ordered sodii iodidi and bromidi, aa gr. i. Pulv. Sacch. alb., gr. i.  $\mathfrak{r}$ . Ft. pulv. in capsules. S. One three times a day. This treatment she continued for some months with entire relief from the noises.

This patient presented herself again February 20, 1885, with a relapse of almost all the symptoms. She had, besides, an ulcer in the meatus. This was treated by local applications and general treatment, as before. It was remarkable that she should have a return of the symptoms at the same time of the year two years after, showing that it was partly atmospheric.

March 3. Reports that she is very much better; the ulcer in the meatus almost well; continued the ointment of boro-glyceride, with powder of hydrochlorate of cocaine and gum arabic to the mouth of the Eustachian tube and relaxed naso-pharyngeal mucous membrane.

March 12. Still improving; has passed, by

the use of the pills, some ascarides lumbricoides, and, fearing that they may have given rise to irritation, she was directed  $\frac{1}{2}$ -grain doses of santonine in lozenges three times a day before meals, to be followed, after the use of twelve, by a dose of castor oil and 20 drops of oil of turpentine.

March 24, 1884. Slight return of the noises, with pain in the nape of the neck. The ulcer in the meatus more irritated; made application to it, and sprayed the pharynx, and continued the pills and powder, which she had omitted.

May 23, 1885. Discharged well, and free from all noises.

January, 1886, and again February, the patient had had a slight return of the noises, owing to having undergone great fatigue, exposure, loss of rest, and mental depression in nursing her dying husband. The same treatment was instituted, and a more gradual improvement has taken place.

1502 WALNUT STREET, PHILADELPHIA,  
February, 1886.

#### LAWS RELATING TO CEMETERIES AND BURIAL.

BY HENRY A. RILEY, ESQ., NEW YORK.

PLACES specially set apart for the sepulture of the dead have existed from the earliest times, and the tenure by which such property has been held to its original purpose is as strong and lasting as that by which any property is kept for a public use. The exact tenure under which cemeteries have an existence is regulated by certain general principles of the common law and by the special enactments of the various States. It will be the purpose in a series of articles to state these general principles, and also the laws of the different States where they are noteworthy.

The fact that cremation is coming into favor in this and other civilized countries will necessarily have some effect upon the application of existing laws, but it is not anticipated that much new legislation will be required. Some suggestions, however, in regard to the legal aspects of cremation will be presented later. The vast body of people in civilized countries are as yet firm believers in sepulture as contrasted with incineration or mummification, and the practice of the first mode of disposal of the dead is not likely to be seriously affected for many years to come by the influence of the advocates of cremation. It

will be convenient to treat of the general subject under the following divisions:

I. Origin and organization of cemeteries, public and private.

II. General principles of tenure of cemetery property. Ownership of the grounds, of individual loss, and restraints upon alienation.

III. Removal of the dead. Rights of cemetery authorities, relatives, and the public.

IV. Regulations and rights of access and ornamentation. Penalties for desecration.

V. Special laws of the various States relating to cemeteries and interments.

*I. Origin and Organization of Cemeteries.*—Burial-grounds, in the modern sense, had their origin soon after the recognition of the Christian religion by Constantine, when the then prevalent custom of incineration gave way to sepulture. The catacombs were used by the early Christians both as places of refuge from persecution and for sepulture, and when it became safe to inter the body in graves on the surface of the earth, instead of in subterranean excavations, the latter method gradually was discontinued.

It was not possible, however, for the places of burial to long continue without public recognition, and it seems certain that in many parts of Europe places for sepulture were set aside with solemn forms, either religious or legal. There is no evidence, however, during the first few centuries of the Christian era, that the grounds surrounding churches were used for interments. Still, this custom had become fixed in England prior to the year A.D. 750, for at that period Lord Stowell states that spaces of ground adjoining the churches were carefully enclosed, and solemnly consecrated and appropriated to the burial of those who had been entitled to attend divine service in those churches, and who now became entitled to render back unto those places their remnants to earth, the common mother of mankind, without payment for the ground which they were to occupy, or for the pious offices which solemnized the act of interment.

It appears, therefore, that in England burial-grounds were early established in connection with the parish churches, and this fact has controlled largely the decisions of the courts concerning them.

The whole matter of burial, what was termed the "right of Christian burial," the time and the place, were all under the control of the ecclesiastical courts.

A burial-ground unconnected with a church was an anomaly, and one not under control of the ecclesiastical courts was an impossibility.

This state of affairs existed until a comparatively recent time, and probably not a public corporation existed before this century for the purpose of affording a place for interment.

In this country we have followed the example of England as regards burial-places, the rites of interment being universally religious in the colonial times, and the ownership of the grounds being in the parish, town, or city.

The formation of large cemeteries unconnected with separate churches is a matter of very recent date, and is due largely to the increase of population and the absolute necessity of securing burial-places away from the centres of population.

The term cemetery now seems to be very largely applied to these independent organizations, which are either public or private.

If public, they may be owned by a church, by the town, or some corresponding political community, or by a corporation specially formed for the purpose. Private cemeteries are comparatively few. They are small, and are used only for the interment of persons belonging to a family, or a small number of families, or to an organization like a society. The great majority of cemeteries at this time are connected with churches, but the tendency now is in the opposite direction of corporate ownership, and in the large cities there is practically no opportunity for interment, except as afforded by these corporations.

In London the danger to the health of the teeming population led to a great deal of agitation on the subject long before the Burial Act of 1855 closed the church-yard cemeteries within the limits of the city to interments. Between the years 1840 and 1855 there had been frequent parliamentary inquiries, and a great mass of data accumulated, showing the harmful effect these interments had had upon the general health. A writer in the "Encyclopædia Britannica" says of the church, that "the vaults under the pavements and the small spaces of open ground around them were literally crammed with coffins. In many of the buildings the air was so tainted with the products of corruption as to be a direct and palpable source of disease and death to those who frequent them. In the church-yards, coffins were placed tier above tier in the ground, until they were within a few feet (or sometimes even a few inches) of the surface, and the level of the ground was often raised to that of the lower windows of the church. To make

room for fresh interments the sextons had recourse to the surreptitious removal of bones and partly-decayed remains, and in some cases the contents of the graves were systematically transferred to pits adjacent to the site, the grave-diggers appropriating the coffin-plates, handles, and nails, to be sold as waste metal. The daily papers of thirty years ago contain numerous records of scandals of this kind; while from the official reports it appears that the neighborhood of the churchyards was always unhealthy, the air being vitiated by the gaseous emanations from the graves, and the water, whenever it was obtained from wells, contained organic matter, the source of which could not be mistaken."

As a result of the Burial Act of 1855 interments are now forbidden within most of the cities and towns of Great Britain, and the organization of cemeteries for the burial of large numbers of people has become a necessity.

Prior to 1855 there had been cemeteries organized, but Kensal Green Cemetery, one of the best known of the London cemeteries, and the earliest of them all, was only established as late as 1832. There are now many cemeteries around London, and among them are the following: the Highgate, which commands a fine view of London; Abney Park, formerly the residence of Dr. Watts; the Norwood and Nunhead cemeteries, to the south of London; the West London at Brompton; and the great cemetery at Woking in Surrey, which is only accessible by railway.

Père la Chaise, the great cemetery near Paris, named from the well-known confessor of Louis XIV., who once owned the ground, was laid out as a cemetery in 1804.

In France, outside of Paris, there is a general law requiring every city and town to provide a burial-place beyond its limits, and directing that it shall be properly laid out, and planted and located if possible on rising ground. Interments are to be in separate graves. In Paris there is less regard for individual rights, and the poor are buried in large pits, forty and fifty at a time. They remain undisturbed for five years, and then the ground is smoothed over, a new layer of soil four or five feet thick is made, and the interments begin again.

The history of cemeteries in this country is very similar to that of England. They are very frequently connected with the churches, and this was at the outset the invariable rule.

They are now occasionally owned by the

town or village, and in that case are for the benefit of the whole population.

In other cases they are owned by private corporations, organized under general laws or by special charter.

Private cemeteries are occasionally found in the country for a single or for a few neighboring families, and the laws of some of the States make special reference to these small grounds devoted to a restricted use.

The oldest cemetery in the United States of any note is Mount Auburn, near Boston. It was established in 1831, the year before the formation of Kensal Green, the oldest English public cemetery.

Mount Auburn contains one hundred and twenty-five acres of land, and holds about twenty-five thousand bodies. Forest Hills is the largest cemetery in the neighborhood of Boston. It contains two hundred acres of land, and was established in 1848. Greenwood Cemetery, on the outskirts of the city of Brooklyn, is the largest New York cemetery, and contains four hundred and fifty acres. It was incorporated in 1838, but no interments were made until 1842. There have been within its limits about two hundred and twenty thousand interments. Woodlawn, on the Harlem Railroad, a few miles from New York City, has about four hundred acres of land, and dates from 1863. Some twenty thousand bodies have been interred there. Laurel Hill Cemetery is the best known of the Philadelphia cemeteries, and was laid out in 1836. It contains eighty acres of land on the banks of the Schuylkill River. In 1869 the corporation controlling this cemetery established the West Laurel Hill Cemetery, with two hundred acres of land. Alleghany Cemetery, situated near Pittsburg, is the largest cemetery in Pennsylvania. It dates from 1845, and contains three hundred and sixty acres of land, from many points of which beautiful views can be obtained of the Alleghany and Monongahela Rivers. Green Mount Cemetery is the principal Baltimore cemetery, and was dedicated in 1839. Oak Hill Cemetery is situated two miles from Washington, at Georgetown, D. C., and contains thirty-five acres. It is the best kept of the cemeteries near the national capital. It was established in 1849. Spring Grove Cemetery, near Cincinnati, is the largest cemetery in America. It was opened in 1845, and contains six hundred acres of land. It was laid out by John Notman, the designer of the Laurel Hill Cemetery at Philadelphia, and is very beautiful both from natural attractions and the adornments of art.

Among the other prominent cemeteries are Hollywood near Richmond; Magnolia at Charleston; Bonaventure at Savannah; Elmwood at Memphis; Cave Hill near Louisville; Belle Fontaine at St. Louis; Rose Hill and Oakwood at Chicago; Forest Home near Milwaukee; Lone Mountain at San Francisco. Mount Royal at Montreal, Mount Hermon at Quebec, are the principal Canadian cemeteries.

All of these cemeteries are dwarfed in comparison with the great national cemeteries for the dead soldiers of the civil war. These have been established by Congress, and number in all eighty-two. The following are the largest, and contain the most numerous interments: Andersonville, Ga., holding 13,714 bodies; Arlington, Va., 16,264; Chattanooga, Tenn., 12,962; Chalmette, La., 12,511; Fredericksburg, Va., 15,257; Memphis, Tenn., 13,977; Nashville, Tenn., 16,526; Salisbury, N. C., 12,126; Vicksburg, Miss., 16,600. The total number of interments in all these cemeteries is 321,369, including 173,088 known and 148,281 unknown persons.

The second article will treat of the tenure of cemetery grounds.

#### THE CURE OF FISTULÆ BY INJECTIONS OF OIL OF TURPENTINE.

Cases of anal fistula in connection with carious bone, fistula in connection with the teeth, fistula of the duct of Steno, and atonic fistulæ of various varieties have all been treated with good results by DR. S. CECCHINI by the injection of oil of turpentine (*Wiener Med. Blätter*, January 14, 1886). The reason for the employment of this drug is attributed by the author to the fact that oil of turpentine, on the one side, is a powerful stimulant to the formation of granulations, and, on the other hand, is an antiseptic; while when employed with ordinary care it can produce no unfavorable results. His results are based on a large number of cases, which are reported with very great care and accuracy, and in every appearance seem to warrant reliance on the author's statement. A permanent cure was stated to have been procured in a large number of cases. First, as regards anal fistula, he details seven cases of fistula in four individuals in whom the injection was repeated several times at intervals of three days. The author recommends the employment of syringes with blunt nozzles, then the closing of the opening of the fistula with the finger after the injection has been made, so as to insure

thorough contact. The pain produced is slight, and is quite bearable, although, if necessary, the oil of turpentine may be diluted with olive oil. In five cases the fistulæ were completely cured. In one the patient stopped the treatment before a perfect cure resulted, as he was satisfied with the improvement that followed. In another case of a complete sinuous fistula in a decrepid man considerable improvement was produced, and, after finally being operated upon, the fistula was cured. In cases of fistula in connection with carious bone, four cases are reported in which cure was completely produced in from two to three months. It is hardly necessary to analyze his other cases, except to add that in all a favorable result appears to have been obtained.

#### AN OVERDOSE OF VERATRUM VIRIDE.

DR. F. GREENWELL reports in the *Cincinnati Lancet and Clinic*, December 19, 1885, that he was called recently to see a woman who had taken a teaspoonful of a mixture consisting of oil of tar, tincture of veratrum viride, and simple syrup, each 2 drachms, which she had taken for asthma. Her breathing was greatly disturbed, she was gasping for breath, and complained of loss of vision, while the pulse was only 36 per minute. Thirty drops each of aromatic spirits of ammonia and Hoffmann's anodyne were given with 1 ounce of brandy, and this brought the pulse up somewhat, though in a few moments she began to complain of cramp and pains in the arm. One grain of opium was then given, followed by the brandy. The next day she had entirely recovered.

#### A NEW ANTI-SEPTIC.

CKIANDI BEY has published a number of communications on the bisulphide of carbon, which, contrary to the statements of chemists, he states to be soluble in water in the proportion of 1 part to 2000 of water. This weak solution, according to his observation, entirely prevents every fermentation, and therefore suggested itself to him as a good antiseptic. The author, in the *Centralbl. für Chirurgie*, December 12, 1885, highly recommends this solution in nearly all cases where a disinfectant is required. He has employed it in the treatment of diseases of the mouth and in suppuration with chronic inflammation of the mucous membrane. We have already referred to its use in typhoid fever in arresting the diarrhoea and disinfecting the stools.

### THE SUCCESS OF THE NEW TREATMENT OF DIPHTHERIA BY THE GALVANO-CAUTERY.

IN our last issue we directed the attention of our readers to the singular and noteworthy coincidence that simultaneously from two different quarters, but manifestly independently of each other, a method of treatment was proposed for diphtheria which was claimed to produce most satisfactory results, viz., the application of the galvano-cautery. We have repeatedly and forcibly emphasized our proneness towards pessimism regarding the countless panegyrics in the therapeutic field that have come to us lately from abroad; yet the claims of the above method of treatment seem to be based on some solid facts.

Medical literature informs us that the idea of employing the glowing iron as a radical cure for septic processes of mucous membranes is not a new one. An American ophthalmologist, Dr. Martinache, of San Francisco, appears to have been the first to practise this cauterization of mucous membranes. Later, Dr. Gayet, of Lyons, also an ophthalmologist, likewise adopted this treatment; and as early as 1857 the *Union Médicale* published favor-

able reports of the cauterization treatment in diphtheria. But the deficient understanding of the actual nature of the diphtheritic and other septic processes and primitive means of executing the cauterization naturally rendered all such attempts in those days little available. The merit of having revived the ancient practice, and of exhibiting the thermo-cauterization of the diphtheritic membrane in its most perfect imaginable form, viz., by the galvano-caustic loop, belongs to Dr. Bloebaum, of Koblenz (Rhenish Prussia). From various German journals, especially the *Deutsche Medizinische Zeitung* of January 18, 1886, we have gathered some reliable information regarding this vitally important topic, which we desire to present to our readers.

Bloebaum was for a year or two previous to the announcement of his cautery treatment of diphtheria engaged in experiments intended to elucidate the effect of the galvano-cautery in various septic, and especially diphtheritic, processes which were artificially produced for the purpose. He noted that on the cornea the galvanic cauterization behaved in no respect as an inflammatory irritant, but, on the contrary, proved a powerful stimulant to tissue-regeneration, and, last but not least, evinced perfect *antiseptic virtues*.

It was wonderful, says Bloebaum, to note how young diphtheritic pigeons, which were already cyanotic and unable to feed, after a single cauterization could on the following morning fly about and eat freely. In these young animals, in which the pharyngeal mucous and submucous tissues are of course much more delicate than in man, no inflammatory swelling of the cauterized parts and its surroundings could be detected; on the contrary, they looked healthier than before, and in a few days healed altogether. After sufficient and satisfactory observation on animals, Bloebaum proceeded to employ the galvano-cauterization in the treatment of diphtheria in man. From a number of successfully treated cases of diphtheria, Bloebaum details two in the quoted number of the *Deutsche Medizinische Zeitung*, which testify to the incredibly prompt effect of the cauterization. Besides gargles of ice-water, no other medicinal interference of any kind was admitted. Let us briefly review the first case, which our author reports with full names and dates.

On the 17th of the month the patient was driven to his house and presented for treatment. Profoundly ataxic form of diphtheria; patient unable to get in or out of the carriage unassisted; fever high; cervical glands swollen.

The patient was cauterized and seen by the doctor on the following morning, the 18th. The fever was found to have disappeared, the cervical glands to have almost wholly resumed their normal size, and the diphtheritic deposit to have almost entirely vanished. Only a few suspicious spots still were present, which were cauterized anew. On the 19th the patient failed to report at the physician's house, although ordered previously to do so. Called to the house, Bloebaum found his patient absolutely well, but was charged to treat other members of the same family, who had likewise contracted diphtheria. The same treatment proved the same prompt success in these and other instances as in the case detailed above. Bloebaum asserts that the procedure appears wholly painless, as no expression of pain was ever uttered during the cauterization, although the intense burn-odor suggested the thoroughness of the act. Healthy granulations were in every instance noted to have sprung up from the cauterized part.

Reviewing these apparently reliable statements of Dr. Bloebaum, we can readily single out the rare advantages of the cauterization treatment of diphtheria, and formulate our conclusions as follows:

1. The galvano-cauterization of the diphtheritic membrane produces no pain, or only a minimal one.
2. The thoroughly cauterized part is rendered absolutely sterile, and forbids the development of microbic life.
3. Fever disappears soon after the cauterization.
4. No inflammatory secondary effects set in.
5. Every physician is able to execute the cauterization, even without an assistant.\*
6. No constitutional medicinal treatment is needed in addition to the cauterization.
7. Though the statistics of diphtheria cases thus treated are of course yet very limited, the thousands of ulcers of the cornea treated and cured in the same manner allow of very favorable prospects regarding the treatment of diphtheria with the galvanic cautery.

Concerning the latter proposition, a few additional thoughts suggest themselves, as the deductions from this analogy might not appear evident at first sight. But nobody will object to our assertion that all microbes, no matter whether they belong to the cholera, tubercle, or syphilis bacilli, or the pathogenetic

agents of diphtheria, are killed by fire, and that a soil treated by fire can give no nourishment whatever to such microbes as perhaps have escaped death by fire. Of course, we need not wonder at the imperfect results obtained with the intended cauterization of septic or diphtheritic membranes by the old physicians, as intimated above.

But a cauterization in its present perfect form insures an ideal *antiseptic* effect, and in our estimation is destined to supersede in the treatment of diphtheria every other therapeutic procedure; *provided, what is affirmed about the method shall be substantiated upon wider experience.*

In the rapid and certain destruction of the septic agents and products, in its local and distinctly circumscribed effect, in the ease and harmlessness of its application,—viewed from all sides,—the galvano-caustic treatment of diphtheria recommends itself warmly to every practitioner who has hitherto felt his helplessness against one of the most ravaging of all known diseases. It must be, therefore, henceforth our aim in the treatment of diphtheria to change the infectious character of the affection into a traumatic one, and to thus obtain not only the most favorable conditions for tissue-regeneration, but also to prevent by the destruction of the pathogenetic parasites their entrance into the circulation, the subsequent constitutional intoxication, and, lastly, the sequelæ of the affection.

#### HYPNOTICS AND HYPNONE.

IN no branch of therapeutics is the search being prosecuted with more eagerness than among hypnotics. But we cannot say that at present there are more than three substances which can be relied upon as having distinctly established themselves in the favor of the profession. One is the old stand-by opium, the second is chloral, and the third is hyoscine. To this perhaps should be added a fourth remedy,—paraldehyde. The general action of opium as a hypnotic is so well known by every one that it is a waste of words to say much about it, but perhaps we may be pardoned for calling attention to the fact that when the insomnia is produced by pain this drug remains still *facile princeps*. When, however, the case is one of pure insomnia, opium is, in our experience, distinctly inferior to chloral. Chloral does not relieve pain, although it may force sleep. Experiments show that the rabbit under its influence, if the dose has not been too large, is absolutely hyperæ-

\* Dr. Bloebaum has constructed an especial pharyngeal mirror for the purpose, which, with a transportable apparatus, is sold by Eschbaum in Bonn (Prussia).

thetic, though when left alone it sleeps quietly. We have often heard neuralgic patients violently affirm that they would never again take chloral, because the sleep was accompanied by frightful dreams of agonized suffering,—a sleep built upon an under-foundation of pain. In very many cases the combination of chloral and morphine acts much better than does either remedy, producing sleep more certainly and with less disturbance of the digestion, and less after-depression. Fifteen grains of chloral, with a quarter of a grain of morphine, will almost always triumph, and in mild cases ten grains and an eighth are sufficient.

A very important fact to be borne in mind in regard to persons in whom the after-depression from opium is excessive is, that this after-effect can be largely prevented by using the deodorized tincture of opium, and administering with it a full dose of the bromide of potassium. How the bromide acts under these circumstances we do not know, but that it does act is certain. Perhaps in three-fourths of the cases it renders the opiate tolerable to the system of the person who otherwise could not endure it.

Hyoscine was practically introduced to the profession through our columns, and we have therefore watched it make its way with considerable interest. It seems to be clearly proven that it is a most invaluable remedy, finding especial application to those cases of insomnia in which the sleeplessness is the result of excited brain action. Whether this excitation passes beyond the lines of sanity, or simply reaches the condition in which a perpetual tumult of thoughts and ideas crowd away sleep, hyoscine is of equal service. In very many of these cases opium in less than immoderate dose produces absolute wakefulness. There is one possible application of hyoscine which has not yet, as far as we know, been made, and in which we are very anxious to see the alkaloid tested; namely, the delirium of low fevers. As we have before stated, when there is any difficulty about the throat and larynx, the drug should not be used; but in the low delirium of typhoid and other allied fevers, hyoscine ought to produce quiet sleep without injury.

With paraldehyde we have had a very small amount of experience, but as a simple soporific it does seem to have some power, and is probably similar in its action on the cerebrum to chloral, but much inferior to that drug.

The latest candidate for popular favor is the so-called hypnone. This substance is soluble in water, has a horrible taste, recall-

ing that of creasote, and can only be properly administered in gelatin capsules or pearls. It is also violently irritant, and, being soluble in oil, it may be given in it. The most recent researches with this substance, however, throw very grave doubt upon its practical value. It undoubtedly will produce in the lower animals and in man, given in sufficient doses, profound sleep. In toxic amounts it causes insensibility and asphyxia, preceded often by hæmaturia.

In the report recently presented to the Academy of Sciences by Messrs. Mairat and Combemale (*Comptes Rend.*, ci. 1506; cii. 178) it is stated that in experimenting with four different samples presenting the characters attributed to acetophenone, or hypnone, obtained from different houses of good repute, they found that its immediate effects upon animals had nothing in common with sleep. Administered in therapeutic doses to a healthy man and to twenty-one patients suffering from mental affections, in only one case was sleep produced; in none of the others did it exercise any hypnotic action. So negative were these results that the reporters suspected whether they had been using true hypnone. Therefore, following Friedel's process for the preparation of 'acetophenone, a mixture of acetate and benzoate of lime was submitted to dry distillation. Upon heating the mixture over a bare fire, a brownish liquid distilled over, having the odor of bitter almonds, and not crystallizing at 0° C. like acetophenone. Intravenous and hypodermic injections of this liquid produced in animals results similar to those obtained with acetophenone, but of greater intensity. In one case an intravenous injection produced syncope, and afterwards vomitings, alternating with profound sleep for upwards of six hours, the animal dying two days afterwards. When the mixture was heated gradually, a heavy yellow oily liquid passed over, having an odor recalling that of acetophenone, but not crystallizing at 0° C. This liquid also produced symptoms similar to those produced by acetophenone, but in much smaller doses.

Hopeine is the narcotic alkaloid of American hops isolated from all extractive matters, and has hitherto been but little used, though it is said to be a powerful and pure hypnotic. In England, Williamson, Smith, and Roberts have examined the physiological action and gauged the therapeutic efficacy of the drug. All three observers unite in regarding the new hypnotic favorably. In the *Wiener Mediz. Presse* of January 31, we also note that Dr. Lang, of Vienna, has tried a

limited sample of hopeïne, which was forwarded to him from London. It is, according to Lang's sample, a white powder of an exceedingly bitter taste, and insoluble in water. Lang reports the results of his trials with the drug in a few cases of phthisis pulmonalis and idiopathic insomnia. In a phthisical woman, who for an entire week had taken every night fifteen grains of urethan without effect, a dose of  $\frac{3}{10}$  gr. of hopeïne sufficed to produce a sleep lasting for five hours, and being but once interrupted by coughing. The same small dose produced also in other phthisical patients a sleep of four, five, and six hours' duration without any considerable interruption through coughing.

It is asserted that hopeïne-salicylate is a very eligible preparation; it comes, dissolved in "condensed beer," in small vials, containing each 12 c.c. (1 c.c. (16 gtt.) of the solution corresponding to  $\frac{1}{100}$  gr. of hopeïne), and is given in a dose of 20 to 40 drops. It is likewise a very active hypnotic. In children having measles or chicken-pox Lang succeeded repeatedly in producing an otherwise unattainable sleep of four to eight hours' duration by 4 to 8 drops of this medicine. Subcutaneously the muriate of hopeïne can be employed in a watery solution, and in Lang's hands has never failed to act promptly, and to be exempt from all secondary untoward effects. Lang does not hesitate to rank hopeïne among the best of our hypnotics in view of its promptness and innocuousness. In connection with this subject it should, however, be stated that, according to Bardet, Pettit, and Dujardin-Beaumetz, hopeïne is identical with morphine, and this statement is so made as to leave the inference that hopeïne is simply morphine under another name. In our next issue we may possibly have some further information on this subject to lay before our readers.

The same pharmacologist reports in the *Wiener Medizinische Presse* of February 7, 1886, on another supposed hypnotic, viz., the glucoside of boldo. There appears to be but little known about this drug. In the *THERAPEUTIC GAZETTE* of May, 1885 (p. 500), we find it mentioned as a substitute for cocaine, and the statement that as such it had been used successfully on the cornea by Laborde. According to Lang, it is a yellowish-white powder, which produces, when placed on the tongue, a pricking and slightly burning sensation. It is affirmed to be a hypnotic, and to cure liver-affections and catarrhs of the bladder. Lang tried boldo in a vesicular catarrh resulting from a gonorrhœa, and with

a perfect failure; neither pain nor dysuria were relieved in the slightest by the drug. Lang leaves the merit of disproving the hypnotic virtues of boldo to another ambitious experimenter.

#### IDIOSYNCRASIES.

THERE are probably very few physicians who have not from time to time been seriously annoyed by the idiosyncrasies of people in regard to drugs. These idiosyncrasies are without reason that can be discovered, and cannot be allowed for by any *a priori* judgment. Perhaps one of the most serious is the case of susceptibility to the action of mercurials which some people possess. We have seen a fraction of a grain of calomel cause a most frightful and really serious salivation. A very curious circumstance which we have noticed in one or two such cases is that blue mass was tolerated when the systems exhibited the most violent reaction against calomel.

There is a very well-known practitioner in Philadelphia who is most violently affected by the odor of hyacinths. We have known a single sprig of hyacinth, put in his room without his knowledge, to cause in a few moments sick stomach, followed by violent, repeated retching, and great general depression, amounting almost to syncope. It would appear as though, if he were shut up in the room with a single hyacinth bulb in full bloom, it would cause his death. A curious feature of this case is, that the emanations will produce so much disturbance of his system without his perceiving the odor.

Another very curious idiosyncrasy that has come under our notice is in a lady who is thrown into fainting fits by eating the smallest piece of butter. We have known her tried by those who thought her condition was purely imaginative by placing a small piece of butter in a dish of mashed potatoes and giving her a tablespoonful, after telling her that there was no butter in it. In a very few minutes she fell off her chair in a condition of swooning.

Some years ago one of the residents of the Pennsylvania Hospital was forced to resign because the moment he went to work in the surgical wards he became afflicted with a crop of boils which would have disrupted the heart of Job with envy. It was only years afterwards that the unfortunate doctor discovered that the boils were produced by the emanations of turpentine, which was, at that time, used in the wards for cleaning off the skin of

patients to which the adhesive plaster had remained.

Not long since there came into our office a gentleman to whom morphine was given for the purpose of relieving pain. Contrary to all expectations, a violent diarrhoea was produced by the alkaloid; indeed, so excessive was the flux that it was stopped with difficulty. In this case the idiosyncrasy appears to have been inherited, as the father of the patient was accustomed to use habitually paregoric as a laxative; a teaspoonful of this fluid taken at night would always produce soft evacuations in the morning.

As already stated, there is no way of foreseeing these peculiarities. It ought, therefore, to be the habitual practice on the part of the physician, when prescribing for a patient with whom he has not before been acquainted, to ask as to the existence of any such peculiarities, and to pay attention to the answers received.

#### THE PROPHYLACTIC TREATMENT OF PUERPERAL ECLAMPSIA BY HOT- WATER BATHS.

**T**HERAPEUTICS owes much to the Medical School of Vienna. Oppolzer, Skoda, and their successors have made many valuable contributions to the world's stock of knowledge of the means of modifying morbid processes. If there is one characteristic of these additions to therapeutical lore more marked than another, it is their thorough reliability. Methods for the modification of diseased action are usually tested on a large number of cases through a considerable period of time by competent observers. The *rationale* of the physiological action of a sanatory procedure is determined as far as possible, and its limitations approximately settled. Only then does the ambitious therapist announce his results to the professional public.

An example of the truth of this statement is presented in the prophylactic treatment of eclampsia in the pregnant, parturient, and puerperal woman by hot-water baths. It may not be amiss to say, right here, that in Vienna eclampsia, occurring during pregnancy, parturition, or the puerperium, is invariably regarded as a symptom of acute renal insufficiency.

The preventive treatment of the convulsive disorders of Bright's disease by hot-water baths—a very ancient method—is fully recognized in the *Allgemeines Krankenhaus*, but its greatest technical perfection, particularly as applied

to women during the period of reproduction, is observed in the obstetrical clinics of Professors Carl and Gustav Braun. Breus, formerly assistant to Gustav Braun (*"Zur Therapie der puerperalen Eclampsie," Arch. f. Gynak., xix. p. 219*), has clearly described the plan pursued in the wards already mentioned. The patient, perfectly naked, is immersed up to the neck in a portable bath of a temperature of about 102° F. The tub is covered with heavy woollen blankets, which permit the head to protrude. The temperature of the water is then gradually elevated to 110° or 112° F. An ice-bag or a linen cloth, wrung out of cold water, applied to the head relieves the distressing cephalic symptoms which are occasionally observed at this time. Thirst is satisfied and diuresis promoted by the copious imbibition of water. The patient is allowed to remain in the hot-water bath about thirty minutes. She is then removed, wrapped in hot sheets, and put to bed between two layers of heavy woollen blankets, and covered in so that only the face is visible. Profuse perspiration soon begins, and is kept up for two or three hours. After this vigorous sweating the patient frequently falls into a refreshing slumber. If she feels faint in the bath or bed, a glassful of one of the light native wines usually restores the circulatory equilibrium. Great care is taken in the gradual cooling off of the surfaces when the woman rises from the bed. According to the indications in the concrete case, the baths are repeated from once to twice daily for an indefinite period of time. Under this simple mode of treatment wonderful results are frequently noted. The troublesome headache is relieved, dropsical effusions abate, and the amount of albumen in the urine is diminished.

The query as to the effect of hot-water baths on uterine contraction naturally arises. Hot-water sitz-baths have been employed for years in all the Vienna obstetrical clinics as a simple and innocent means of stimulating uterine contractions in tardy labors. On *a priori* grounds, it would seem in a high degree probable that the calling of *all* the skin reflexes into functional activity should result in the invocation of uterine contractions. Breus has not been able to observe any such effect; but then, as remarked by Sippel, chloral was exhibited *per rectum* in the cases observed before the bath was taken.

A. Sippel (*"Die wehenerregende Wirkung heisser Vollbäder," Centralblatt f. Gynäkologie, No. 44, October 31, 1885*) has recently

called attention to this important subject. In two cases of severe Bright's disease in pregnancy, with threatening eclampsia, premature labor followed the hot-water bath and diaphoresis within fourteen and one and one-half hours respectively. The first case, primipara, 24 years old, was in the thirty-second week of pregnancy; the second case, multipara, 27 years old, was in the thirty-fifth week.

To determine the effect of hot-water baths on the normal pregnant woman, Sippel selected a woman pregnant in the thirty-fourth week. She had a generally-contracted pelvis, and the induction of premature labor was indicated. After baths on two successive days (without the subsequent packing in bed), sensible uterine contractions occurred, but gradually passed away. On the third morning the same patient was placed in the hot-water bath; pains were complained of while she was in the water, and labor terminated normally some twenty-four hours later. The writer has recently observed the induction of premature labor to follow the hot-water bath in two cases of Bright's disease in pregnancy, with threatened eclampsia.

The possibility of the induction of premature labor under these conditions, however, is seldom a contraindication to the employment of the hot-water bath. The evacuation of the uterine contents, in the very large majority of cases, is an event for which the clinician most devoutly prays. To obstetricians who accept Robert Barnes's very advanced views, this possibility constitutes absolutely no contraindication. That distinguished obstetrician, at a recent meeting of the British Gynæcological Society, uttered words to the effect that "the necessity for inducing labor" was imperative "as soon as albuminuria was fairly established." (*The British Gynæcological Journal*, Part III., November, 1885, page 313.)

As a method of induction of premature labor, the hot-water bath is entirely devoid of danger from sepsis. Further trial, however, is necessary to determine its efficiency.

#### A FRENCH MENU.

THERE is an old saying that he who makes two blades of grass grow where only one grew before is the greatest of human benefactors; and we suppose that he who makes two pounds of flesh where there had been but one is even superior to the man of grass. On this principle M. E. Decroix, one of the superior veterinary officers of the French army, is

worthy of all commendation. During the bitter scenes of Crimean and Algerian warfare, and especially in the frightful expedition of Maroc in 1859, Decroix was much impressed by the fact that whilst the soldiers were starving for want of food, horses killed in battle were rotting by hundreds on the plain and in the mountain. Remembering, also, that in 1850 Geoffrey Saint-Hilaire had shown that the French production of cattle was only sufficient to supply one-third of the population fully with animal food, Decroix came to the conclusion to experimentally determine whether the horse was or was not a good human food. As the result of his labors, and of the venturesome toil of others whom he had imbued with his own spirit, horse-meat was proven to be wholesome and good for food, so that when the siege of Paris brought hunger and famine into every faubourg, the eating of horses became a fashion. The result is that in 1884, in Paris and its environs, 14,548 horses, 346 donkeys, and 32 mules were converted into the æsthetic flesh of Frenchmen. Pushing his researches, Decroix has shown that the flesh of a horse dead of acute diseases is, when properly prepared, thoroughly wholesome. He has fed upon the flesh of beasts dead of pneumonia, of strangulated hernia, of hydrothorax, cerebral concussion, colic, purulent pyæmia from chronic inflammation of the joints, typhoid pleuro-pneumonia, and even of glanders acute and chronic. Surely the courage and the devotion which would lead a man to such lengths is worthy of the Iron Cross.

The naïveté which this Frenchman still retains in his old age is remarkable, and we read with much enjoyment how the "*bistek*" prepared from a horse dead from acute glanders had a taste *sui generis*, which was attributed to the free administration of alcohol to the unfortunate beast. If any of our readers want to study how to prepare soup from glandered horses, and the peculiarities which it possesses, we refer them to the recent memoir which Decroix has presented to the Academy of Medicine.

The results obtained by M. Decroix led him to the conclusion that the meat which is condemned by the Paris slaughter-houses and by the government inspectors might very well be employed for feeding the poor; therefore is it that he has fed upon animals dead of cancer, of phthisis, of fever, of unknown diseases, of pyæmia, and even with great labor he squeezed out, from the reluctant dugs of a cow in the death agonies from contagious typhoid, a

little milk, which he drank without suffering. Chickens dead of cholera, pigs dead of the various diseases to which hog flesh is heir, came not amiss to our experimenter; but at last he reached even his limit, and when, on the 25th of November, 1863, he ate the raw flesh of a dog dead of hydrophobia, he confesses that it was "*malgré une grande répugnance*," and that the taste did not altogether please him.

#### ON MILK-WINE (KEFIR).

IN two previous issues of the GAZETTE (March and April) we have referred to the high dietetic and even therapeutic value of the various fermentation products of milk, and expressed the hope that these preparations would become as popular in our sick-rooms as they are abroad. The necessity of importing the kefir ferment from Russia, however, has no doubt impeded hitherto the introduction of this variety of koumiss to a large extent; and if we at present suggest an easy and ever-ready way of procuring an identical ferment in every household, we hope to have enhanced the chances of recovery for a class of affections in which the power of drugs is, unfortunately, restricted.

In the liquid which is obtained during and after the preparation of butter,—the so-called buttermilk (also in cream which has become distinctly sour),—we have a ferment which for all practical purposes is stated to be identical with the kefir ferment, and can be utilized for the preparation of beverages containing all the nutritive and stimulant virtues of koumiss. According to a recently published instruction of Dr. Rogelmann, of Graz (Austria), in the *Deutsche Medicinal Zeitung* of January 14, 1886, one volume of buttermilk is to be mixed with one to two volumes of sweet milk, poured in a bottle, and allowed to stand. In three hours active fermentation will set in, which in about three days will be at an end. The product is a fluid smelling like wine, and containing alcohol, carbonic acid, lactic acid, and caseine. The following precautions are to be observed in this in every way simple and inexpensive procedure. The sweet milk used ought not to be wholly freed from the cream, and the bottles ought to be of a size that the milk fills only two-thirds of them. The fermenting milk is to be shaken daily vigorously (about three or four times), during which manipulation a cork is placed firmly in the bottle, but removed after the shaking in order to allow the carbonic acid to escape.

The opened bottle is to be placed in a horizontal position at least twice daily for a period of ten minutes, in order to let fresh air take the place of carbonic acid, and to thus prevent the stoppage of fermentation. If a very effervescent liquid be desired, the bottles are toward the close of the fermentation process allowed to stand continuously in a perpendicular position. In order to obtain new quantities of this "milk-wine," we add to a certain quantity of sweet milk one-fifth its volume of milk thus fermented, and are so able to continue this production *ad libitum*. The most favorable temperature for the preparation of this milk-wine is 15° (C.).

#### ON THE CONTAGIOUSNESS OF PAROTITIS.

THE number of constitutional affections in which hitherto no microbes of a supposed pathogenetic nature have been found is rapidly decreasing, and we have to announce parotitis as the latest addition to the list, as appears from a paper of Dr. Olivier, published in the *Revue Mensuelle des Maladies de l'Enfance* (*Deutsche Med. Zeit.*, January 23, 1886).

Our author found in the blood, saliva, and urine of parotitic patients cocci partly isolated partly as duplicocci, or united in chains and heaps; he also noted small bacilli, which he believed to be identical with those described by Capitan and Charrin. These bacilli showed mostly a spontaneous motility, and could be colored in gentian-violet, while the cocci remained uncolored by this fluid. The pathogenetic nature of these microbes is best illustrated by the fact of their disappearance from the economy during convalescence. In the saliva of healthy children are likewise to be found micrococci, but they differ from those found during parotitis by being easily colored in gentian-violet. Olivier explains the metastatic phenomena in mammæ and testes often observed during parotitis by the immigration of the specific microbes into these glands. In children in whom the poorly-developed genital organs possess but little blood, these metastatic processes occur almost never.

#### VIVISECTION VERSUS FEMININE VANITY.

AT the recent meeting of the Society for the Restriction of Vivisection in Philadelphia it was stated that the doctors were in disagreement about this matter. In conse-

quence of this, the subject was made a special order of business at a late meeting of the College of Physicians, and was fully announced. The result was that, after prolonged discussion, by vote of sixty to one, the resolutions were passed, and a county committee of five, with power to represent the college in opposing any attempts to procure new laws upon this subject, declaring that no further legislation on the subject of vivisection is desirable in Pennsylvania. This, of course, settles the question as to what is the opinion of the profession on the subject in Philadelphia, and the power of the profession is so great that we supposed it practically settles, at least for years to come, the question as to the enacting of any more laws.

Contrasting with the enormous amount of fuss which is made over this subject in proportion to the extremely small amount of pain that is inflicted is the destruction of our native birds, as set forth in a late number of that very valuable and interesting journal, *Science*. There are about four or five places in Pennsylvania where vivisection is performed to a very limited extent, and only for a portion of the year. To regulate this, in the last few years many thousand dollars have been spent and many hours of time wasted on the part of the enthusiasts who have devoted themselves to the subject. Whilst this has been going on, our sea-coasts, forests, mountains, and dales are being rapidly depopulated in the most cruel manner in order that the bonnets of women may be properly ornamented. It is estimated that there are in the United States about ten million persons wearing birds as personal ornaments. If it be considered that the life of a bird-skin in a bonnet is two years, and that the average for each wearer is one bird, to meet this demand five million birds must be annually killed. One bird to each hat is not an over-average, as frequently eight, ten, and twelve birds' heads can be found on one bonnet, and no allowance is made in the estimate for the amount of feathers and bird-skins used in ornamenting dresses and houses. Of course, a large proportion of this five million of birds comes from abroad. But, on the other hand, enormous amounts of bird-skins are exported. It seems that in the neighborhood of Cobb's Island, on the coast of Virginia, last year one enterprising woman secured forty thousand bird-skins, which she shipped to Paris. The result is that upon Cobb's Island the air is untroubled longer with terns and sea-gulls. Cape Cod has been made a similar desert.

Forty thousand terns were killed there in a single season, under the auspices of one person, for the hatting trade. The heronry of Florida have been decimated, and the whole Gulf coast almost stripped of its avian inhabitants. It is not merely the sea-gulls and similar birds against whom this war has been waged, but even the smallest winged inhabitants of the interior must suffer. The slaughter, of course, is greatest in the neighborhood of the large cities, and seventy thousand birds, it is said, were supplied to the New York dealers on Long Island in the year 1884. A New York taxidermist said recently that he had in his store thirty thousand crows, red-winged blackbirds, and snow-birds from the State of New Jersey. In a single auction-store in London during the months ending with April, 1885, about eight hundred thousand bird-skins were sold under the hammer.

Without occupying further space, we think we have said enough to show the enormous scale upon which this slaughter is going on. For every bird obtained in condition suitable for taxidermists, at least one other bird is too much mutilated for use, or escapes in a wounded condition to die. When it is remembered that these birds are all killed by shooting, and that only a small proportion of them are destroyed outright; that they are torn, disembowelled, and wounded in every possible way; that many of them live on, some for minutes, others for hours and even for days, it can be seen that the sum total slain thus produced is something really gigantic, and perhaps no sight was ever witnessed showing more completely the utter and unreasonable folly of ordinary human nature than the dancing plumes of the women at the meeting of the Antivivisection Society as the souls of the wearers were harrowed over the few dozen cats, rabbits, and dogs that had during the past year suffered for the benefit of medical science.

## Reports on Therapeutic Progress.

---

### *PERMANGANATE OF POTASSIUM IN THE TREATMENT OF AMENORRHOEA.*

DR. FORDYCE BARKER, writing in the *New York Med. Journ.*, February 27, 1886, states that he had long been incredulous as to whether any article known to the materia medica could be regarded as possessing the property of a direct emmenagogue. Of course,

he had, in common with other physicians, had his full share of experience in the use, for this purpose of iron, aloes, myrrh, savine, rue, and other agents, and had often seen menstruation return apparently as a consequence; but he had never been convinced that this result was due to the direct influence of the drug on the uterus or its functions. Latterly he had obtained special success in the use of capsules of apiol two or three times a day, commencing three days before the menstrual period. For the past four years, however, he has used the permanganate of potassium exclusively when an emmenagogue was indicated, except in a limited class of cases of sudden suppression. Dr. Barker divides the cases which he treated with this remedy into three groups, mentioning them in the order of their frequency:

*First.*—Young ladies between the ages of fourteen and nineteen, who come from the country "to finish their education." Home-sickness, entire change of their habits of life and associations, over-tax of their brain-power from their own or their teachers' ambition to accomplish more in a given time than they ought to attempt, not infrequently lead to an arrest of menstruation.

*Second.*—Ladies, both young and married, who suffer severely from sea-sickness, that have left some European port within a few days of the menstrual period. With such, amenorrhœa of longer or shorter duration is almost sure to follow.

*Third.*—Ladies between thirty and forty, generally married, some of whom have borne children, who rapidly begin to gain flesh, grow stout, while at the same time menstruation decreases in both duration and quantity, until at last it is only a mere pretence. This is generally attended with annoying nerve-disturbances, pelvic weight, sometimes hemorrhoids, and often mental depression from the apprehension of growing old prematurely.

Dr. Barker affirms that when in either of these classes of cases he has prescribed the permanganate of potassium he has never known it to fail, but he adds that the use of the medicine should, if necessary, be continued for at least three months. Of course, Dr. Barker does not prescribe this agent in cases where the amenorrhœa is due to some grave constitutional disease, nor does he rely on it for the relief of sudden suppression due to cold, moral shock, and in acute disease. In such cases he thinks the pulsatilla, opiates, and local agents, such as fomentations and hot rectal enemas, are generally successful.

The above paper of Dr. Barker was called

forth by an address on the same subject read by DR. BILLINGTON before the meeting of the New York Academy of Medicine, held February 17, 1886. Dr. Billington first showed the importance of the subject by a reference to the sixty-nine cases reported by Ringer and Murrell, and quoted their conclusions regarding the class of cases in which the drug was useful. Since Ringer and Murrell's article appeared the remedy had been employed by many other physicians, both abroad and in America, and the results had been tolerably uniform. The author's experience had been limited to four cases; but these, taken in connection with those reported by Ringer and other authors, possessed some significance. In the first case the patient was eighteen years old, chlorotic, and suffering from malarial poisoning. For the nine months that she was under observation she menstruated only once, and then just after the administration of permanganate of potassium. She positively refused, however, to continue the medicine because of the gastric disturbance which it caused. The second case was that of a girl of seventeen, who had menstruated regularly until a certain exposure to the rain, when the flow became scanty and almost colorless; her health then declined, and she suffered from headache, coldness of the extremities, pallor, etc. Besides other remedies, she was given permanganate of potassium in 2-grain capsules three times a day, but they were discontinued for a time on account of gastric irritability. Before the next period, the condition of the stomach having been improved, she was able to resume the capsules, when she menstruated normally, and rapidly regained perfect health. The third case was that of a girl of about eighteen, who had menstruated regularly, but, without known cause, had ceased to menstruate, and become chlorotic and feeble. Other remedies having failed to restore the menses, permanganate of potassium succeeded. On one or two occasions, however, while the remedy was being continued, a period passed without any flow, probably because such large doses were not given as were said to be necessary in some cases. In the fourth case the patient, who was sixteen years old, had begun to menstruate a year before. The flow had appeared only four or five times, and she had palpitation and shortness of breath. She began with 2-grain capsules of permanganate of potassium three times a day; and during the night of the first day, when she had taken three capsules, the flow came on. This patient also

complained after taking the medicine of an unnatural sensation under the upper part of the sternum.

With regard to the manner in which the remedy acted, different views were held. The author agreed with those who did not believe the beneficial effect was due to its improving the blood and anæmic state; some patients so benefited were not anæmic, but, on the contrary, were plethoric. There were also conflicting views as to whether permanganate of potassium or other forms of manganese acted as general blood-restoratives. Ringer denied it; others held an affirmative view. Regarding the question whether binoxide of manganese was equally efficient as an emmenagogue as permanganate of potassium, the published testimony was not abundant; but Ringer and Murrell thought it was, while Dr. T. Gaillard Thomas considered it equally efficient and much better tolerated by the stomach.

Regarding the method of administration, it had been seen that permanganate of potassium often produced severe gastric disturbance, and some preparations were more likely to produce this result than others. The author preferred to give it in capsules. Its use should be begun a week before the expected menstruation, and, if it acted favorably, might be continued during the interval, or be suspended and resumed at a corresponding period the next month.

DR. THOMAS wrote that he had used both permanganate of potassium and binoxide of manganese frequently in disordered menstrual function. He preferred the binoxide. He had also employed it in chlorosis and anæmia, and had obtained better results than he had heretofore obtained with iron. While he recognized the fact that all medicines which were intended to regulate the menstrual function were uncertain, still he looked upon the preparations of manganese for use in such cases as valuable additions to the Pharmacopœia.

DR. C. C. LEE had used permanganate of potassium with two classes of patients designated by Dr. Barker, namely, young girls who, from habits of indolence or want of hygienic care, had ceased to menstruate, and women who had ceased to menstruate after a sea-voyage. He had given it in different forms, and had found trouble in getting patients to take it on account of gastric disturbance. Latterly he had employed mucilage as a vehicle, and in this form the drug had not produced gastric irritation. He did not think it was of much practical use as an emmena-

agogue outside of a certain range. In cases of chlorosis in which the menses seemed to be suppressed for want of vitality, permanganate of potassium was of temporary benefit. But even in this class of cases, if it was necessary to keep up its administration for four or five months, it would then be found, on suspending its use, that the result was not permanent. He had, therefore, come to rely upon it with less confidence than he inferred Dr. Billington did, and he now combined its use with that of other measures, such as massage, hygienic care, and the use of chlorate of potassium. His experience with the drug, however, had been limited to ten or twelve cases. He had never used it for metrorrhagia or menorrhagia, nor could he comprehend how a remedy which could be understood to be only a stimulant to the general nervous system through the oxygen which it imparted to the blood should be of benefit in these conditions.

DR. W. H. THOMSON said that about fifteen years ago permanganate of potassium was recommended in an article in the *Boston Medical and Surgical Journal* for cases of nervous exhaustion, to be administered in about  $\frac{1}{4}$ -grain doses, larger doses, it was stated, causing gastritis and symptoms of poisoning. He employed it in such cases with negative results. He had previously, and again subsequently, employed syrup of iodide of iron and manganese in chlorosis, but the taste of that preparation was extremely disagreeable, and it was with great difficulty that patients could be induced to take it. Since reading Ringer's article, and a subsequent article by Bartholow, he had given permanganate of potassium in three different affections, administering it in 2-grain doses; but in all the gastric distress had been so great that a fair trial could not be made, and he therefore had no favorable results to report. His own belief was that the action of the drug was specific or special; that it did not act as a general restorative, although manganese existed in minute quantity in the human body. How manganese operated was to him a chemical mystery. He could not understand how Dr. Lee could get its action if he administered it in mucilage, for its reduction in the presence of liquids containing organic matter was almost immediate.

#### HYOSCINE HYDROBROMATE AS A HYPNOTIC.

DR. E. M. SCHAEFFER published in the *Maryland Med. Journal*, February 13, 1886, a report of his experience with hyosine hy-

drobromate as a hypnotic in the Maryland Hospital for the Insane. In the main his results accord with those already published in the *GAZETTE* by Dr. Wetherill and Dr. Wood. Dr. Schaeffer, however, takes exception to the statement of Dr. Wetherill as to the production of sweating as one example of the physiological actions of this drug. Dr. Schaeffer has employed hyoscine in doses of from  $\frac{1}{16}$  to  $\frac{1}{8}$  of a grain over one hundred times, and has never observed this effect. The cases which were treated by Dr. Schaeffer included acute and chronic mania, mania with hystero-epilepsy, chorea with insanity, and melancholia. As a hypnotic, doses of  $\frac{1}{16}$  to  $\frac{1}{8}$  of a grain, given at night, have acted well, and this drug has therefore the merit of smallness of dose added to tastelessness. For ordinary insomnia he thinks that it will give very satisfactory results in doses of  $\frac{1}{16}$  of a grain. As a cerebro-spinal sedative it has proved of decided value, quieting the insane in their talkative, noisy, and demonstrative phases. There is no enlargement of the pupil noticed, or dryness of the throat complained of. The excitement may occasionally seem to be increased when the dose is rather large. The unpleasant effects, such as nausea, headache, and loss of appetite, have been noticed in one case. Taking  $\frac{1}{16}$  grains three times daily developed a profuse diarrhoea.

#### THE ACTION OF ADONODIN.

At a recent meeting of the Société de Thérapeutique (*Les Nouv. Remèdes*, January 15, 1886) M. Houchard read a note on the therapeutic action of adonodin, and exhibited a number of cardiographic and sphygmographic traces which he had obtained from patients under this mode of treatment.

Adonodin is a glucoside of the adonis vernalis, a plant of the family of Ranunculaceæ. The fresh plant possesses a caustic vesicating property, which is lost on desiccation. This action is utilized in certain countries, such as Africa and Siberia, where a closely allied variety of adonis has received the name of vesicatoria. Vesication is produced by crushing the fresh plant into a pulp between two stones, and applying the pulp to the part. Adonodin was extracted from the plant by Cervello, and prepared under the form of an amorphous, yellowish, bitter powder, and has since then been subjected to experiment by several observers, whose conclusions have already been laid before the readers of the *GAZETTE*. All observers unite in the statement that adonodin

diminishes the frequency of the pulse, at the same time increasing the vigor of the heart's contractions, until finally the heart is arrested in systole. M. Houchard has experimented on guinea-pigs, and has found that after hypodermic injections of  $\frac{1}{16}$  to  $\frac{1}{8}$  of a grain of adonodin the number of respiratory movements and cardiac pulsations are reduced, paralytic phenomena appear, the temperature is reduced, and death results in from fifteen to twenty minutes. In man adonodin may be given in doses of  $\frac{1}{8}$  of a grain in pill form four or five times daily, and Houchard reports a number of observations as to the clinical uses of adonodin. In one case of interstitial nephritis with heart-murmur, anasarca, and commencing asystole, the administration of five or six of these pills of adonodin produced an abundant diuresis, even although sparteine had remained without effect. Adonodin had, however, to be given up temporarily on account of the nausea, vomiting, and diarrhoea which it produced. When its use was again recommenced, the secretion of urine, which in the interval had been decreased, was again rapidly increased from two to six quarts, at the same time the arterial tension became stronger, the pulse more ample and more regular, while the oedema disappeared completely. Again, in a case of typhoid fever, adonodin was found to greatly increase the arterial pressure.

#### THE USE OF NITRO-GLYCERIN IN DIFFERENT FORMS OF NEPHRITIS.

DR. F. P. KINNICUTT has continued his studies on the use of nitro-glycerin, and formulates his conclusions from them as follows, in a paper read before the New York Academy of Medicine at the meeting held on February 16 (*New York Med. Jour.*, February 20, 1886): 1. That in nitro-glycerin, given in small doses frequently repeated, we possessed a powerful agent for lowering increased blood-pressure, which was very commonly associated with uræmic symptoms. 2. That its power to control or relieve many of the paroxysmal disturbances of the nervous system included under the general term uræmia, headache, and asthma especially, was more marked than that of either opium or chloral. 3. That its action in parenchymatous and interstitial nephritis was to increase the amount of urine excreted, and to diminish the quantity of albumen. 4. That in nitro-glycerin we had the means of maintaining

more or less continuously lowered blood-pressure, thus averting or relieving symptoms and prolonging life. Regarding the administration of nitro-glycerin in chronic nephritis, the strength of a single dose should be just within the limits of producing subjective symptoms, and this could be determined only by careful trial in individual cases. It was well from time to time to increase a single dose to the production of subjective symptoms to learn whether the system had not become tolerant from its long use, and, if found necessary, to increase the dose.

DR. W. H. DRAPER, not being able to be present, but knowing the contents of Dr. Kinnicutt's paper, sent some notes, which were read by Dr. W. M. Carpenter. The writer had had many opportunities for observing the efficiency of nitro-glycerin in relieving uræmic headache and asthma. There could be no question, judging from his experience, of the very prompt and decided relief which nitro-glycerin gave from these distressing symptoms, and, though it sometimes failed where opium succeeded, it was certainly to be preferred to opium where it would give relief. In his experience, it had failed in cases of advanced disease, the function of the kidney being wellnigh exhausted and the heart greatly enfeebled. Concerning the ability of nitro-glycerin to control the progress of interstitial nephritis, he had no experience to offer. As to its power to diminish the amount of albumen, he thought a larger number of observations were necessary to establish this result. He was not prepared to say that nitro-glycerin as a cardiac stimulant possessed the advantages over alcohol, opium, and digitalis alleged for it by Dr. Burroughs.

DR. C. L. DANA'S experience with nitro-glycerin had been chiefly in the treatment of nervous disorders, but recently he had had occasion to employ it in six cases of renal disease. He had also administered it to five persons in health, to determine its diuretic effect, and in all it had rapidly and decidedly increased the excretion of urine, but it had to be given in considerable amount. In two of the cases of kidney-disease with acute symptoms, probably ingrafted upon a chronic condition, nitro-glycerin did not cause a diuretic effect. When given in large doses, the drug caused an increased amount of urine, which continued to increase for two or three days after stopping its use, and then began gradually to diminish. This was evident, he thought, from the charts presented by Dr. Kinnicutt as well as from his own cases.

Dr. Kinnicutt called attention to the unreliability of some specimens of nitro-glycerin, and said it should always be tested by producing subjective symptoms.

#### THE DIAGNOSIS OF SEX BEFORE BIRTH.

DR. JUAN BIDART (*Deutsche Med. Zeitung*, January 21, 1886) has endeavored to settle the question as to whether the sex of the fœtus might be determined before birth by the frequency of the fœtal pulse, and with that end in view publishes a note of one hundred cases in which he counted the fœtal pulse-beat at the end of pregnancy. He concludes that when the pulse of the fœtus is under 135 in the minute, in all probability it is of the male sex; while when between 135 and 145 it is a female. He claims that he has been able to foretell the sex of the child ninety-two times out of one hundred.

It is evident that, if these results are reliable, they must be of the greatest importance in deciding a number of questions, such as to whether premature labor should be induced.

#### THE SIGNS OF EARLY PREGNANCY.

In the practice of the gynæcologist, in particular, it is frequently necessary to be positively assured of the non-existence of pregnancy before instituting such local treatment as the exigencies of the case seem to require. In the absence of such assurance, the sole course open to him is to defer treatment for a variable period of time, until the rational history or repeated vaginal and conjoined examination lead him to think that the case is one where treatment, as far as the interior of the uterus is concerned, is contra-indicated, until the ovum, which he finally concludes is probably contained within this organ, has reached maturity and been expelled. Is there any diagnostic sign by means of which, at the first local examination, the existence of pregnancy may be determined with almost positive certainty as early, even, as the fifth week of utero-gestation? Such a sign is offered to us by Hégear, and DR. E. H. GRANDIN (*Med. Record*, February 27, 1886) during the last eighteen months has had frequent opportunity of putting the value of this sign to the test, and has by means of it been able to assert as early as the fourth to the sixth week that gestation existed.

During the first six to eight weeks of pregnancy the changes in the uterus are practi-

cally limited to the body of the organ. The uterine body enlarges, especially in its transverse diameter (antero-posteriorly); the muscular substance becomes less dense. These changes are simply the result of the hyperæmic condition into which the corpus is thrown and kept by the engrafting of the impregnated ovum. As the result of such changes, the uterine body loses its nulliparous pear shape; its contour no longer gradually diminishes as it approaches the uterine neck; the body, on the contrary, bellies out over the cervix in all the transverse diameters, in particular, antero-posteriorly, and the organ, instead of being pear-shaped, resembles very much an old-fashioned, fat-bellied jug.

The above changes in the consistency and shape of the body of the uterus constitute Hégar's sign, and so far, at least in a dozen cases, it has never, according to Dr. Grandin, failed in early diagnosis. The obtaining of this sign requires, of course, a certain expertness in the bimanual palpation, and familiarity with the sensation communicated to the finger by the nulliparous uterus, and the uterus altered pathologically in one or another way. Dr. Grandin has found, however, in his clinical teaching but little difficulty in making even inexpert fingers conscious of the change. In the vast majority of cases, owing to the normally slight anterior curvature of the uterus, the internal examining finger will note this sign to the best advantage in the anterior cul-de-sac. Here the finger, instead of following the line of the cervix in a gentle curve up on to the body, is at once conscious of the body swelling out to a greater or lesser degree, according to the date of impregnation, over the cervix, and at the same time, bimanually, the body is faintly boggy, resilient, compressible. If such be the condition of affairs detected by the local examination, in the absence of rational history, in the absence of slight softening at the tip of the cervix (which may, if present, mean erosion), and of mammary signs and blue discoloration of the vagina (both of which, if present, may mean ovarian disease), Dr. Grandin now unhesitatingly pronounces the patient pregnant. The question arises, Are there other conditions which may simulate the above sign? There are two which might, —distended bladder, and uterus distended by menstrual blood. Neither of these conditions ought, however, to give rise to error, for a necessary prelude to a careful bimanual is evacuation of the bladder by means of the catheter; and retained menstrual blood in the

uterus, if not accomplished physically by imperforate hymen or vagina, would necessarily be suggested by the history (no ground for falsifying here) before sufficient had collected to give rise to even faint fluctuation. Hyperplasia of the corpus uteri cannot simulate this sign, because in this condition the conjoined touch reveals density; sub-involution cannot, because here the uterus is increased in its longitudinal as well as in its transverse diameter, and conjoined touch, while revealing heaviness and softness, does not reveal resiliency and compressibility. The markedly anteflexed corpus uteri, hyperæmic from obstructed circulation, is most likely to simulate Hégar's sign, but in case of such distortion the feeling of resiliency and compressibility is also lacking. In marked retroversion this sign is likely to fail on account of the difficulty of palpating with ease the uterine body.

---

*THE INTRA-PARENCHYMATOUS INJECTIONS OF CORROSIVE SUBLIMATE IN TUBERCULAR PHTHISIS.*

Whether regarded or not as an outcome of the prevalent theory of the microbic origin of phthisis and pneumonia, the fact that these two affections are successfully treated abroad by mercury deserves the attention of the clinician and practitioner. Of the treatment of pneumonia with mercurial ointment, as at present in vogue in the Women's Hospital of St. Petersburg, we shall speak in a subsequent article.

In a recent meeting of the Société des Hôpitaux, as reported in the *Gazette Hebdomadaire de Médecine* of January 15, 1886, Dr. GOUGUENHEIM delivered an address in favor of an active therapeutic treatment of tubercular phthisis, and recommended intra-parenchymatous injections of corrosive sublimate for the purpose. Iodoform was formerly used in this manner with satisfactory results, by Beverley Robinson and Shingleton Smith, while Lépine and Truc had successes with sublimate injections in pneumonia. In the Bichat Hospital watery solutions were used of a dose of  $\frac{1}{100}$  to  $\frac{1}{50}$  of a gramme. The latter rather large dose is only admissible in a case marked by large cavities. It is to be remembered that the solutions ought to be of the temperature of the body. The injections are best made into the first or second intercostal space in a certain distance from the sternum, in order to avoid lesions of the heart and pericardium or of nerves and vessels. Intolerance and pain were noted to be either wholly

absent or at least only minimally present. Occasionally, however, a paroxysmal cough intervened; hæmoptysis was likewise in an exceptional case noted, and of course necessitated the giving up of this treatment. In the largest majority of cases, even if the general constitutional conditions of the patient did not improve, Gougenheim observed a more favorable state of the local conditions after the mercurial treatment. In some instances this latter improvement was strikingly rapid. Râles and tinkling sounds and even expectoration could, if not wholly removed, as happened in exceptional cases, be notably reduced in well-nigh every instance, a result hitherto unattainable by other medication. Of thirty-three cases treated with the mercurial injections, twenty-one must be said to have taken a very favorable termination, two had a doubtful issue in consequence of the change of treatment (hæmoptysis in one case), two left the hospital before completion of the cure, while ten patients died. Among these there were seven cases positively refractory to the mercury; in three others the post-mortem examination revealed an improvement of the local troubles, death having taken place either in consequence of complications or as the result of the general vital depression.

In bronchial catarrh and suspected pleuritis these infra-parenchymatous injections of corrosive sublimate were likewise practised, and attended by at least satisfactory results.

As long as a phthisical patient is regarded as doomed, and these injections occasion no pain, it will be worth while to try them, even if only with the view to improve the local lesions.

#### ABORTIVE TREATMENT OF BUBO.

Nearly four years ago Dr. Morse K. Taylor recommended a treatment of bubo by injection of carbolic acid, which he said in nearly all cases ended in speedy and complete recovery. In the *Med. News*, January 23, 1886, Dr. PHILIP F. HARVEY reports ten cases which he treated by this method, in all of which a prompt cure resulted. The method employed is as follows:

The skin covering the bubo is first chilled with a spray of ether; the enlargement is then grasped between the thumb and finger of the left hand, held firmly, and the point of a hypodermic syringe thrust obliquely into the centre of the gland, to a depth equalling about two-thirds of the narrowest diameter of the tumor. The syringe being charged with an

8-grain solution of carbolic acid to the ounce of distilled water, 20 to 30 minims are slowly injected. A bag of shot or sand, weighing about three pounds, is then placed on the bubo and held in place by tapes; although in favorable cases this may not be necessary. The stage of the disease at which the injection yields the best results is when the gland has attained a sufficient size to admit of the free infiltration of the injected fluid throughout its structure. At such time, one thorough injection is usually sufficient to effect a cure, and this without the patient foregoing his usual avocation. When the gland is smaller and harder, it may be necessary to repeat the injection once or oftener.

To insure a full measure of success, the following details should be borne in mind and carried out:

1. The time of election is just prior to suppuration.

2. Rest, a laxative, and reduced diet assist in the dispersion of the swelling, rest being the most important adjunct.

3. The exact point at which the injected fluid should be delivered in the bubo is a matter of importance; as also its manner of delivery. These conditions can be satisfied, however, by the exercise of ordinary intelligence and care.

#### EPILEPSY CONSEQUENT ON OCULAR INJURY CURED BY ENUCLEATING THE INJURED EYE.

According to the Paris correspondent of the *British Med. Journ.*, January 16, 1886, at a recent meeting of the Academy of Medicine, M. GALEZOWSKI read notes on a case in which epilepsy resulted from the loss of an eye, consequent on an accident during hunting; the eye was reduced to a stump. Six years later epilepsy declared itself, and the left eye, hitherto perfectly healthy, exhibited hemorrhagic neuroretinitis. MM. Vulpian, Hardy, Gueneau de Mussy, and Legrand du Saulle were consulted. It was decided in consultation to enucleate the damaged eye. The epileptic attacks, which had been of daily occurrence, disappeared. The patient's general health and the sight of the left eye improved, although it remained imperfect. M. Galezowski attributed the cerebral disturbance that existed to sympathetic reflex action; he believed that inflammation was transmitted by the vessels and vaso-motor nerves. In another instance, observed and reported by the same oculist, there were also sympathetic phenom-

ena exhibited under the form of neuroretinitis, accompanied by obliteration of the vessels of the retina. The patient was 47 years of age; he had lost the eye when 8 years old; nearly forty years subsequently the seat of the eye became tender, and touching it produced pain; also sympathetic symptoms were manifested in the healthy eye. In the eye which was enucleated six years after the hunting accident, both the choroid and the vitreous body exhibited osseous degeneration. There was also lymphoid infiltration in the tissues of the optic nerve, and its fibres were reduced to fine filaments. The walls of the vessels were atheromatous and thickened, so much so in some places that they were quite obliterated.

#### TREATMENT OF PNEUMONIA WITH INUNCTIONS OF MERCURIAL OINTMENT.

The treatment of pneumonia with mercurial ointment, proposed by BARTHEL and MORITZ, of St. Petersburg, in the *St. Pet. Med. Woch.* of January 16, 1886, is, as a typically antiphlogistic measure, of a pretty old date; for as early as 1850 the mercurial treatment was recommended by Wittich as a check and in opposition to the practice of French physicians to the employment of abstraction of blood. Of course the calomel which Wittich and his contemporaries prescribed was not exhibited in the antiseptic sense as the mercury ordered at present by the above named Russian physicians. But no matter whether the metal is supposed to reduce the excess of fibrin, diminish congestion of the lungs, and favor resorption of the inflammatory exsudate, or whether we mean to kill by its action the specific etiological factors of the disease, —Friedländer's pathogenetic microbes,—the mercurial treatment of pneumonia is usually attended by good results.

The success of iodoform and similar inunctions in a large number of peritonitic and meningitic affections induced Barthel and Moritz, chiefs of the Obuchow Female Hospital of St. Petersburg, to try the inunction of mercurial ointment in croupous pneumonia.

That mercury, if applied in the form of an ointment to the skin, was absorbed, of course is a well-established fact, and has been known ever since Voit's memorable publication, "The Absorption of Mercury and its Combinations in the Body." Augsburg, 1857.

For the last two years this has been the only medication used in croupous pneumonia,

and shows a favorable mortality-rate as compared with the records of former years. The mortality-rate of 31.4 was lowered by the mercurial treatment to 6.2 per cent., certainly a remarkable difference.

The inunctions are to be begun with at once when the diagnosis is established. Morning and night a drachm is to be used; in very grave cases 3 instead of 2 drachms may be used daily. The inunction is to be made on the extremities, abdomen, and back; the thorax is to be left exempt, as the skin in this locality is wanted intact for the water-compress. (The German routine treatment of respiratory affections, *vide* Berlin letter of GAZETTE, January, 1886.)

There were used in one case 2 drachms of mercurial ointment; in three cases, 3 drachms; in seven cases, 4 drachms; in six cases, 5 drachms; in one case, 6 drachms; in one case, 7 drachms; in seven cases, 8 drachms; in three cases, 9 drachms; in one case, 10 drachms; in one case, 12 drachms; in one case, 13 drachms.

In spite of directly ordered gargles of chlorate of potassium, the authors observed in some instances slight gingivitis and moderate salivation, though never a serious stomatitis or colitis. Alongside of these inunctions the inevitable compress was applied on the thorax, as intimated above, and digitalis and quinine given, according to the indications of the case.

In view of the very favorable record produced by this mercurial treatment, we can only support the recommendation by our Russian colleagues of mercury in croupous pneumonia.

#### ON THE ADVANCED OPERATIVE TREATMENT FOR THE RADICAL CURE OF HERNIA.

At the meeting of the Medical Society of the County of New York, held January 25, 1886, DR. ROBERT ABBE (*New York Med. Journ.*, February 6, 1886) read a paper with this title, in which he first mentioned conditions which rendered a radical cure of hernia desirable, and then briefly referred to a number of operations which had been performed, which, although their safety might recommend them, had been condemned because of their failure to cure. This remark might almost be said to be applicable also to Heaton's method. This method seemed to have been used more commonly in this country than in Europe. The operation with which the paper had specially to deal, however, was the open one, which the author had adopted in twenty-one cases. The method

of procedure adopted by surgeons in this country and abroad was essentially the same. In Liverpool, especially, the silver-wire suture was employed instead of catgut for closure of the ring. In view of the importance of an operation for the radical cure of hernia, exact information regarding the histories of patients operated upon should be had, in order to judge of the real merits of the procedure. For this reason he gave the histories somewhat in detail of the twenty-one cases in which he had done the open operation. In sixteen of the cases there was not strangulation, and in a portion of the others the symptoms of strangulation were not very marked. The result of the treatment had led him to ask two questions,—first, was the open operation a safe one? and, second, did it effect a radical cure? If we judged by the statistics of Liverpool surgeons we must admit that it was safe, but such good results had not been obtained elsewhere. Other statistics showed a death-rate of one in eight. It was true, however, that this showed the result of treatment in the worst cases, for only such had usually been subjected to operation. There were dangers arising from adherent intestine, incarcerated omentum, fatty heart, feeble health, etc. Again, we had to face the fact of possible hemorrhage. Banks, of Liverpool, had referred to a case of hemorrhage in which the patient recovered after laparotomy and securing of the bleeding point. The accident had also occurred in the hands of experienced surgeons in New York. It took place in one of the cases reported by the author, in the manner in which he believed it usually occurred, namely, by shrinkage of the mass of omental tissue and loosening of the ligature. To avoid this accident he advised the use of carbolized silk, ligating the broad and thick mass of omental tissue three, four, or even five times, and in addition securing any bleeding vessels on the cut surface. Peritonitis, suppuration, and hemorrhage had been the three bugbears which had led surgeons to let the hernial sac alone. But the greatest danger from peritonitis was due to the development of erysipelas, and the occurrence of this accident was not very likely if antiseptic methods were strictly observed. Inasmuch as hemorrhage had occurred in the hands of the most careful and experienced surgeons, it might be a question whether it could be adequately guarded against in all cases. In one of the twenty-one cases death occurred from fatty heart and intestinal obstruction brought on by the relations of the returned omental stump. It was

not probable that, had laparotomy been performed, the constricting band could have been divided. In a third case the open operation was performed, and at the same sitting some varicose veins of the leg were operated on, which resulted in suppuration and death. The hernial wound was doing well. The author was decidedly of the opinion that suppuration and union by granulation in the canal and about the ring led to a much better final result than primary union did. This was also the estimation of the granulation process by English surgeons. Adhesive inflammation about the ring, excited by whatever method, was delusive. The induration following Heaton's method usually disappeared within a month. If we could bar the ring tight, and keep it barred, we might keep back pressure, but the catgut suture became absorbed within a week, and allowed the strain to come upon the soft tissues too soon. The patient should support the parts from without many weeks, and perhaps many months, after the operation. With regard to a return of the hernia, it was extremely probable that there would be a recurrence within a year or two. It was much less likely to follow an operation upon a femoral hernia than upon an inguinal hernia. But recurrence of the hernia was not a sign of failure of the operation, for the patient was almost always restored from complete invalidism to perfect health and ability to do his work. The sixteen unstrangulated herniæ which he had operated upon had all been unmanageable, and all of the patients expressed great satisfaction at the result of the operation.

DR. A. G. GERSTER had performed the radical operation in twenty-five or more cases. In the larger number kelotomy had had to be performed under urgent conditions, and this operation was supplemented by that for radical cure. In eight or nine of the cases there was no strangulation, but the symptoms were so distressing, principally on account of adhesion of the omentum or gut, that the patients were unable to wear a truss and attend to their business. He thought the results were rather better in those cases in which there was not a largely distended abdominal ring. Of all the cases, death had taken place in three, and in each of them kelotomy had had to be performed. One patient died of necrosis of the gut, which had been returned under the supposition that it was viable. In another case follicular diphtheritic inflammation developed, and in the third case death was thought to be due to septic peritonitis from

necrosis of the gut, but an autopsy was not permitted. In all the cases in which kelotomy was not indicated the patients recovered without disturbance. He therefore thought the operation, in the hands of one familiar with all the details of antiseptic methods, could be considered safe. As to relapses, he had not yet seen a case in which a relapse had not taken place, or would not have taken place had not an instrument prevented it. He thought, with the author of the paper, that when a cicatricial plug formed it was more solid than if simple adhesive inflammation took place. A truss should always be worn after the operation.

DR. R. F. WEIR had performed the operation for radical cure in a number of cases of strangulated hernia, but in such cases it was to be taken without the saying that we should seek to close the canal if possible. For herniæ not strangulated he had performed the operation eight times, and he thought we were justified in undertaking it in cases in which the hernia was large, perhaps irreducible, rendering a truss useless, and disabling the patient for work. But he had seen three deaths from hemorrhage after the open operation, occurring in the practice of surgeons of experience. In two or three of his own cases the amount of suppuration and constitutional disturbance after the operation had been very considerable, and he had been anxious lest peritonitis should develop. If, after the best of these operations, attended by even a moderate amount of risk, the patient was obliged to wear a light truss, he would ask why extend the operation to those cases of reducible herniæ which could already be kept up with a light truss? He had not yet lost faith in Heaton's injection method for cases of mild hernia. He thought it would result in cure in from one-third to one-half of such cases, and he should be unwilling to adopt the open operation.

DR. O. A. WHITE said that he had devised a modification of Wutzer's instrument for invaginating the hernial sac and exciting adhesive inflammation with the intent of plugging the canal. The modified instrument contained two needles instead of one, and was lighter than the original, weighing only half an ounce. He had operated in over forty cases, and he believed it had not been necessary to operate twice in more than five cases. The instrument was left in place about four days, a truss was put on, and the patient was kept in the recumbent posture until it was safe for him to get up.

DR. ABBE, in closing the discussion, said he was afraid to use such instruments as the one presented by Dr. White, through fear the needles might pierce the intestine and give rise to dangerous inflammation. History, it seemed, did not record such accidents, but he had seen three cases in which he thought the instrument, had it been used, must have pierced the intestine. By the open method one could see what he was doing. The cases in which the operation seemed to be specially applicable were those in which there was troublesome incarceration, and those in which a reducible hernia continued to grow larger and larger, and could not be controlled with a truss. Such cases of hernia, if femoral, were more dangerous than if inguinal, and the operation offered surer relief.

#### *THE INFLUENCE OF SEA-BATHS IN SCROFULOSIS.*

The prize essay of the Paris Academy of Medicine, entitled "*De l'Influence des Bains de Mer Sur la Scrophule des Enfants*, par DR. CAZIN" (Paris, 1885, Asselin & Houzeau), recommends itself as a highly valuable contribution to the literature of the therapeutics of scrofulosis. The author of the work, physician-in-chief of the famous French resort, Berck-sur-Mer, has an experience of an unusual extent, forty-one thousand seven hundred and eighty-three scrofulous children having come as patients under his observation. He prescribes, 1, sea-air; 2, external application of the sea-water; 3, internal use of it. The principal beneficial effect, however, emanates, in Cazin's estimation, from the sea-air, which, by virtue of its ozone, purity, and aseptic properties, materially favors the blood-making process and the general innervation.

The sea-water is ordered either in the form of the bath in the open sea or in the warmed basin; besides these are used compressors, soaked in sea-water, against swollen glands and joint-inflammations, irrigations against atonic ulcers and inflammations of the bony structures, and, finally, douches and atomization of warm sea-water. Cazin thinks but little of the beneficial effects of the warm sand-bath; at least he has never observed any therapeutic advantages from its use.

Sea-water taken internally in small doses increases, according to Cazin's observation, the appetite and corrects a faulty digestion. Bread and other victuals prepared with the aid of sea-water contribute likewise to the tonic and

resolvent effects of the sea-cure. The author details the treatment of the various forms of scrofulosis, such as gummata, cold abscesses, affections of the skin, infantile leucorrhœa, swelling of the glands, diseases of the eyes and eyelids, affections of the throat and nerves, and bone and joint defects. Even tuberculosis of the scrotum and scrofulosis of the intestines are discussed, all in an interesting and strictly scientific manner.

However agreeable and even salutary a short stay at the sea-shore is for a scrofulous child, permanent curative or reparative effects can only be anticipated from a stay of years, or, at the best, of several months, though there are notable exceptions to the latter observation. An interesting view of Cazin is the following: The tuberculosis of poor children can be cured more rapidly, thoroughly, and easily than that of rich children, the former being acquired, the latter inherited. Cazin also asserts that the phthisical process is checked and slowed by a protracted sojourn on the sea-shore.

In conclusion, we find an interesting review of the sea-shore resorts for scrofulous children existing in the various countries. The author, of course, only refers to places of a charitable nature. The oldest institution of this kind, and probably the most famous, is Margate, in England, founded in 1796; then comes Viareggio, in Switzerland, and next in age stands Cette, in France.

The numerical statistics of the principal countries are as follows: There are three resorts in England, fifteen in Italy, five in France, one in Austria, three in Holland, five in Germany, one in South America, three in North America. The latter resorts are: 1, Atlantic City, Children's Sea-Shore House; 2, Boston, Sea-Shore Home for Sick Children; 3, Barth, Summer Home for Children.

#### *TREATMENT OF PELVIC ABSCESS IN WOMEN BY INCISION AND DRAINAGE.*

DR. PAUL F. MUNDÉ draws the following conclusions from an elaborate paper with the above title published in the *American Journal of Obstetrics*, February, 1886:

1. Pelvic abscess in the female is not very common in proportion to the great frequency of pelvic exudations, and probably does not occur in more than ten per cent. of all cases, the majority of exudations terminating in spontaneous absorption.

2. Pelvic abscess may be either extra-

peritoneal, the result of cellulitis (by far the most common variety), or intra-peritoneal, the consequence of pelvic peritonitis. If intra-peritoneal, the adhesive inflammation between pelvic viscera and intestines may so seal the abscess-cavity as to render it *practically extra-peritoneal*.

Abscess of the ovary and pyosalpinx do not belong in the category of "pelvic abscess" proper, and do not fall under the same therapeutic rules, unless when, by agglutination to the abdominal wall or to Douglas's pouch, they become virtually extra-peritoneal.

3. Small deep-seated pelvic abscess, not exceeding a capacity of two ounces, and minute multiple abscesses in the cellular tissue can often be permanently cured by evacuating the pus thoroughly with the aspirator. The surrounding exudation is then rapidly absorbed.

4. About one-half of the abscesses open spontaneously into the vagina, rectum, bladder, or through the abdominal wall and ischiatic fossa. These cases may gradually recover without treatment, or the sinuses may persist until closed by surgical interference.

5. Abscesses containing more than two ounces of pus should be opened by free incision along an exploring needle or grooved director, cleared of *débris* by finger or blunt curette, and drained and irrigated, if necessary, through a drainage-tube.

6. This incision should be made at the spot where the pus points most distinctly, which is usually the vaginal vault.

7. In a certain number of cases the pus points through the abdominal wall, generally in the iliac fossa, and the incision should then be ample, and free drainage should be secured.

8. When the pus has burrowed deep into the pelvic cavity, and a probe can be passed from the abdominal incision down to the vaginal roof, mere abdomino-cutaneous drainage will not suffice, and a counter-opening must be made in the vagina and a drainage-tube carried through from the abdominal wound into the vagina. This drainage-tube may have to be worn for months. In making this incision care should be taken not to wound the bladder.

9. The opening of a pelvic abscess which points through the abdominal wall does not differ from and is no more dangerous than the same operation elsewhere on the cutaneous surface of the body. It is not an "abdominal section" or a "laparotomy" in the sense that these terms are now used to indicate the surgical opening of the peritoneal cavity.

10. Chronic pelvic abscesses, which have burst spontaneously and have discharged through the vagina, rectum, or elsewhere for months or years, are exceedingly difficult to cure. This is particularly the case when the opening is high up in the rectum. A counter-opening in the vagina, or enlarging the opening if there situated, the curette, stimulant irrigation, etc., may occasionally succeed, but usually fail.

11. A perityphlitic abscess may point through the abdominal wall and simulate a pelvic abscess proper. Aspiration will settle the diagnosis; the treatment is the same.

12. The majority of cases of pelvic abscess recover; at least the mortality is small.

#### ON IODOL.

DR. GEORG BENNO SCHMIDT reports in the *Berliner Klinische Wochenschrift* on the advantages of iodol, as ascertained from the use of this antiseptic at the surgical clinics of Heidelberg. Iodol, or tetraiodopyrol, has a light-brown color, and is almost odorless, in which respect it offers a decided advantage over iodoform. Unfortunately, it is not very soluble in water, only in a proportion of 1 to 5000. In alcohol it dissolves in three times its weight. The drug is employed in the following manner:

1. As a powder, in the same manner as iodoform. Being a finer powder, it enters and covers the part more completely than the former. It forms no scurf (in opposition with iodoform) on the wound, renders the secretions odorless, favors the formation of healthy granulations, and has a general salutary influence on the nutrition of the affected part.

2. As solution, in sixteen parts of alcohol and thirty-four parts of glycerin, for the saturation of uterine or rectal tampons. It is also injected in this form into emptied or scraped-out abscesses.

3. As gauze.

4. In combination with vaseline and colloidum.

In no instances, in spite of its extensive use, were any symptoms of intoxication observed, nor was ever any iodine after its use discoverable in the urine. It is probable that its action depends upon the generation of free iodine, though we have no definite data yet regarding this point. At all events, its action is prompt and harmless, and offers no small advantage over the iodoform in the absence of any odor, though its poor solubility and its

(at present) high price are equally great objections.

#### ARTERIAL LIGATION AS A PROPHYLACTIC MEASURE AFTER SUDDEN, COMPLETE, AND PERMANENT OCCLUSION OF THE CHIEF VEIN AT THE ROOT OF AN EXTREMITY.

This subject depends for its interest and importance on these two questions:

1. When the chief vein of an extremity has been suddenly, completely, and permanently occluded at its root, are the collateral venous blood-paths always sufficiently ample to admit such a flow of blood through them that permanent circulatory and nutritive disturbances will not supervene?

2. If, in any appreciable proportion of cases, permanent circulatory and nutritive disturbances are likely to supervene upon such venous occlusion, what prophylactic effect, if any, would be exerted by the diminution of the force and volume of the arterial blood-supply of the limb?

These two questions form the basis of an elaborate paper published by DR. LEWIS S. PILCHER in the *Annals of Surgery*, February, 1886, from which he draws the following conclusions:

1. Serious circulatory and nutritive disturbances are to be apprehended: *a*, in the upper extremity, when, in addition to the occlusion of the main vein at its root, simultaneous occlusion of any considerable number of the lesser and collateral branches has also taken place; *b*, in the lower extremity, when the occlusion of the main vein at its root is sudden and complete, and has not been preceded by any conditions which might have occasioned a previous dilatation of collateral channels or the development of new ones.

2. The accidents of excessive oedema and of gangrene, when they occur, are due to the intense and active congestion of the limb, through the arteries, with blood for which there is no adequate outlet.

3. The development of collateral paths is not by the breaking down of valve-barriers at the entrance of large collateral trunks, but by the dilatation of a multitude of minute branchlets. To effect this an increased arterial *vis a tergo* is not required. Any increase in the normal blood-pressure is attended with danger of overwhelming and fatally choking up the somewhat slowly enlarging collateral radicles.

4. The diminution of the amount of arterial blood which enters a limb whose chief venous

outlets have become occluded down to an amount not greatly in excess of that which can readily find an outlet from it through paths still remaining, is the first great indication to be fulfilled in the treatment.

5. Whatever method is adopted to restrain the flooding of a limb with arterial blood, it must still permit the entrance of a supply sufficient for the nutrition of the limb. For this reason, in the lower limb, ligation of the common femoral is to be avoided, especially in the light of the disastrous results of such ligations already recorded.

6. Ligation of the axillary artery in the upper extremity, and of the superficial femoral in the lower, are safe expedients, and to be adopted as prophylactic measures whenever occlusion of the venous outlets of a limb is so great as to hazard the integrity of the limb by reason of the circulatory stasis produced.

#### PROFESSOR WINTERNITZ ON THE OBESITY CURES.

In the issue of the 7th of February, 1886, of the *Wien. Med. Presse* we find the conclusion of a series of articles written by PROF. WINTERNITZ, which are of a rather polemic tone, against the numerous obesity cures which have of late attracted so much attention. We shall probably find an opportunity in another number of the GAZETTE to refer to these interesting papers, which conclude as follows: Methodic excitation of sweat, influence of cold, appropriate and systematical work increases the physiological fat-combustion so powerfully that these factors not only deserve more attention than has been hitherto bestowed upon them, but also render useless the strict and one-sided cures as employed at present.

#### THE USES OF PYROGALLIC ACID IN DERMATOLOGY, AND SOME OF THE DANGERS ATTENDING ITS APPLICATION.

About seven years ago pyrogalllic acid was introduced as a substitute for chrysophanic acid in the treatment of psoriasis, and has since been used in a variety of skin lesions with much success. At times, however, its application has been followed by poisonous effects, and the drug has consequently largely been given up.

Experience, however, has shown that it is by far the most satisfactory method we possess for the treatment of lupus. The mode

of application as recommended by Schwimmer is as follows:

Vaseline is first applied for several days, or as long as necessary to remove all secondary morbid products, scales, secretions, and dirt; a ten per cent. pyrogalllic ointment is then applied during from four to seven days, being renewed two or three times daily. Vaseline is now to be applied again for one day to remove all of the acid. The entire suppurating surface is now to be covered with the mercurial plaster, under which healing takes place in from ten days to two weeks. This process may be gone through with several times until no more tubercles appear. Prof. Schwimmer says the treatment of a case seldom exceeds three or four months. A speedier and much better resolution of the most advanced and wide-spreading lesions is found to take place under this combined plan of treatment than could be accomplished by the combined treatment of scarification and the thermo-cautery.

DR. CHARLES W. ALLEN (*Journ. Cutaneous and Venereal Diseases*, January, 1886) has employed this mode of treatment in five cases of lupus with quite favorable results. Pyrogalllic acid has also been used with success in the treatment of chancroids, psoriasis, and a variety of other skin-diseases, some of which are illustrated by other cases reported by Dr. Allen. The dangers, however, attending the uses of this agent are twofold. They may be either constitutional effects or local injuries to the healthy skin: of the former, cases have been reported in which the external use of pyrogalllic acid ointment produced chill, rigors, or shivering, preceded possibly by malaise and headache, and coming on rather suddenly, at a variable time from the beginning of the applications. There are usually diarrhoeal stools and vomiting of glairy mucus. The patient soon sinks into a state of collapse with sunken eyes, pallid or cyanosed appearance of the lips, a peculiar greenish hue of the skin, elevation of the pulse-beat and temperature, and acceleration of respiration with dyspnoea. The urine becomes dark brown or black, of high specific gravity, and usually contains hæmoglobin and albumen. The reflexes are diminished. In the early stages there is marked insomnia and restlessness. Towards the close there may be coma. The dyspnoea is due to pulmonary oedema and congestion of the lungs. There may be a condition of general anasarca.

The symptoms persist only so long as the poison is being eliminated, and when this has been accomplished, convalescence is good and

rapid, provided the patient's strength be maintained.\* In these four cases we find two deaths and two recoveries.

As to treatment, that adopted by Besnier, in the case in which the patient's life was saved after being despaired of, appears rational. He was led to make use of the oxygen inhalations by the brilliant results obtained from it in the intoxication from carbon dioxide, in true asphyxia, and in malignant syphilis. He looks upon the vomiting and diarrhoea as salutary, and does not advise their being checked.

These cases, of which only about half a dozen have been reported, show that it is unsafe to practise friction over an extended surface at one time, and that a mild ointment should be used,—not over five grains employed in the twenty-four hours. As regards the local action on healthy skin, Dr. Allen himself reports two cases in which the action of the acid overstepped the boundaries of the disease, and caused serious injuries to healthy parts.

Aside from the use of the powdered drug in full strength, and of the five and ten per cent. ointment, Dr. Allen has employed at times the various combinations of pyrogallic acid with gelatin, collodion, and gutta-percha, which of late years have been recommended, and which are now prepared and placed upon the market by a number of firms. In many cases they are greatly to be preferred to other applications, having the advantage over them of cleanliness, ease of application, a certain amount of pressure exercised, and support given to the tissues, etc. The application of the powdered pyrogallic acid causes occasionally thick crusts to form, which may become irritating to the tissues, and which at times are not easily removed.

He has had successful results in psoriasis and other affections, from the employment of a collodion containing about forty grains of pyrogallic acid to the ounce, and the addition of eight or ten drops of castor oil.

This forms an excellent dressing for lesions about the face and other exposed parts. When first applied to a raw surface some pain is experienced, but this soon passes away. It had seemed that from these fixed dressings only a slight effect of the drug could be obtained, but he has been surprised at times to see how marked an effect is produced by them.

To procure, however, a powerful and speedy result, it is well at all times to apply the powder to the lesions, and, after drying of all secretions, to paint over a medicated collodion or traumaticine.

In conclusion, then, we find that in pyrogallic acid we have a drug valuable, not only in psoriasis, for the treatment of which affection it was first introduced, but furnishing one of the means of combating other and more serious diseases.

That its application is not without dangers both to the general system and to the body's healthy surface. That it is capable of producing death in the one case, and extensive sloughing in the other. That although the application of the drug in its full strength as a powder is efficacious, it is attended with some disadvantages. The crystals should be powdered before being applied.

For many cases a well-made fixed dressing, which adheres nicely to the part, possesses advantages which make it preferable to other applications. This is especially true of lesions of the face and hands.

The intensity of the effect produced appears to be in a measure proportionate to the thickness of the layer of fixed dressing painted upon the parts.

#### PHENIC ACID IN INTERMITTENT FEVER.

DR. NARICH's communication to the *Progrès Médical* of January 30, 1886, on the curative power of phenic acid cannot fail but invite universal attention.

Though no physician would venture to question the miraculous and truly specific influence which the Peruvian bark and its numerous alkaloids exert over the malarial intoxication, it is nevertheless an incontestable fact that occasionally patients are encountered who declare that quinine or any other form of cinchonization has utterly failed to relieve them. And if the physician then, remembering the instructions of his clinical teachers, or those of his text-books, exhibits arsenic, and finds that even this drug does not check the dreaded paroxysms, and that his patient rapidly approaches the limits of exhaustion and nutritive failure, he is truly in no enviable dilemma. Such a patient presented herself for treatment to Dr. Narich, of Smyrna, in Asia Minor, and asked to be treated by a new remedy, as the standard treatment did not benefit her. The patient, who was an intelligent lady of about 35 years, had suffered for the last year of quotidian marsh fever, and had consulted both the Arabian and European physicians of her country. Quinine and bromides were prescribed together, and given for seven days, morning

and night, without producing any results. Arsenic was tried, and failed likewise.\* Having once heard of the advantages of phenic acid in refractory cases of malaria, Dr. Narich resolved to try this drug hypodermically. He dissolved seven grains of the crystals in two fluidounces of water, and injected a small quantity in the right arm. There appeared redness, with elevation, and a somewhat erysipelatous appearance round the point of injection, but disappeared soon after. A second injection was followed by a rather painful induration which lasted four days. His mode of injection was as follows: On the first day he injected one syringeful. On the four succeeding days six syringes daily,—three in the morning and three at night. All in all, thirty-three injections were made. On the fifth day the patient complained of malaise, which increased on the following day, and forced the physician to discontinue the injections on the seventh day. Since the twentieth injection, however, up to date of the publication, for an interval of nine months, the patient has had no more paroxysms.

Although the successful employment in a single case of a certain drug does not suffice to establish its virtues, the phenic acid injections should be borne in mind by those practitioners who have to deal with some very refractory cases of malaria, in which the usual medication has failed.

#### THEINE AS A LOCAL ANALGESIC.

From experiments published in the *GAZETTE* for September, 1885, Dr. Mays drew the conclusion that theine, the active principle of Chinese tea, possesses marked analgesic properties, and his conclusions have been confirmed by Dr. C. H. CASTLE in a paper read before the Cincinnati Medical Society (*Cincinnati Lancet-Clinic*, Feb. 6, 1886). Dr. Castle has used theine three times upon himself. The first time he injected one-sixth of a grain into his left forearm, immediately below the flexure of the elbow-joint. The noticeable effect was remarkably rapid. An angry blush and swelling spread from the point of injection, but what looked like a most delicately tender

spot was singularly devoid of sensation. It was not nor did it become totally anæsthetic, but, in what appeared to be an inflamed area, sensibility was markedly dulled. Presently a numbness such as we feel when a member is beginning to "go to sleep" from pressure upon its supplying nerves stole over his wrist and hand. Little tinglings, scarcely noticeable had not one been on the watch for strange manifestations, came and went in various places. At no time was mobility impaired. The temperature of the left hand was markedly lowered. The effects of the injection lasted about two hours.

The second injection was made under somewhat different circumstances. Dr. Castle rather severely bruised his right hand, and the pain on pressure over the carpo-metacarpal joint of the fifth metacarpal bone was quite severe. He therefore injected one-third grain of theine subcutaneously over the ulnar nerve, just below the elbow.

The same phenomena were noticed as in the first use of the alkaloid: sensibility around the injection was markedly diminished, lower down the forearm and in the wrist and hand less markedly so; the right hand lost as much in temperature as had the left hand previously, but he was disappointed in the analgesic effect he had expected. The extreme sensibility was dulled, and his hand no longer hurt as it had before, but any deep pressure instantly showed that the nerves about the joint still resented the impact of a foreign body with the surface.

The third observation was made again upon the left arm; this time one-half of a grain was used, and, though an accident perhaps somewhat marred the experiment, some points were brought out more prominently. The injection was a deep one, inter-muscular, and the withdrawal of the needle was followed by a slight hemorrhage, sufficient to raise a conical, subcutaneous tumor of a diameter of a one-cent piece. Instantly there was deep-seated pain, probably due to extravasation from the wounded vessel into the inter-muscular planes, and flexion of all the fingers and thumb. Full extension was impossible, partial extension very painful, the painful seats being deeply under the point of injection and the dorsal aspect of the metacarpo-phalangeal joints.

As in former observations, sensibility was affected almost immediately, and in three minutes the left hand was blanched in appearance and almost cold to the touch. His pulse was always full and strong, but slightly more

\* This reminds us that Dr. M. E. Hensler, of West Franklin, Indiana, reported some years ago a number of refractory cases of marsh fever cured by the combination of arsenic and quinine. He gave 15 grs. of quinine morning and evening, and at the same time 3 table-spoonfuls of a solution of  $\frac{1}{2}$  dr. of Fowler's solution in 3  $\frac{1}{3}$  of water.

frequent than normal. Very soon after the injection mental excitement appeared and alternated with spells almost of a fainting character. These were seven or eight in number, commencing soon after the injection and gradually ceasing after the lapse of six or seven hours.

Dr. Castle twice applied theine to the conjunctiva: first with a one per cent. solution, which he thought produced slight anæsthesia, and once in a four per cent. solution, in which the alkaloid could only be kept in solution by maintaining the water at from 125° to 130° F. Instead of anæsthesia, intense injection of the ocular conjunctiva was the only result of the instillation.

He reports three cases in which theine was used for the relief of pain: two of rheumatism and one of neuralgia of the sciatic nerve. In the first cases considerable relief followed the hypodermic injection of one-sixth of a grain of theine. In the last case one-third of a grain of theine was injected over the sciatic nerve, and, while numbness of the leg from the knee down was produced, and a temporary relief of the pain, the next morning the pain had returned. He refers also to another case, of which the nature is not stated, in which there was absolutely no benefit whatever derived from the use of this alkaloid.

#### ON PTOMAINES.

ARMAND and GAUTIER publish some interesting remarks on the obscure but important subject of ptomaines in the *Gazette Hebdomadaire de Médecine* of January 15, 1886, of which we can only abstract some few salient points:

If the fibrin of the blood is well washed and freed from all of its extractive matters, we obtain alkaloids, in form of crystallizable salts, derivatives from the albuminous constituents of the blood. It is established that these alkaloids form even normally in the cells during life, and that they play a considerable but hitherto unexplained rôle in numerous pathological processes. Experimental physiology teaches us that these cadaveric alkaloids, or ptomaines, as they are called, extracted by ether, chloroform, or amylic alcohol, possess an exceedingly toxic nature. The free ptomaines are still more dangerous than their salts, especially those soluble in ether.

Injected into a frog the ptomaines produce the following symptoms: 1, dilatation of pupil; 2, tetanic convulsion, followed soon

by muscular flaccidity; 3, slowing of the heart-beat and pulse, rarely an increased pressure; 4, absolute loss of sensibility in the skin; 5, loss of muscular contraction. In a dog we obtain somewhat different appearances. We note under their influences: 1, irregularity and retraction of the pupil; 2, a remarkable vascular injection of the concha; 3, slowing of the respiration; 4, somnolence, followed by convulsions and death; 5, loss of the muscular contractility, even under electrical irritation. The last phenomenon recalls the intoxication by poisonous mushrooms and by muscarine.

#### THE TREATMENT OF CERTAIN FORMS OF CHRONIC MALARIAL DISORDERS.

DR. S. SOLIS-COHEN read a paper before the recent meeting of the Philadelphia County Medical Society, from which he draws the following conclusions (*Maryland Med. Journ.*, Feb. 6, 1886):

I. That quinine salts are of greatest value in those cases of chronic malaria showing distinct periodicity, and especially if there be a febrile paroxysm; and that in such cases their chief value is prophylactic rather than curative. That the administration of quinine until relief is manifested, and then the withdrawal of the drug, will sometimes bring out a periodicity otherwise masked. The bimuriate of quinine and urea, hypodermically, is the preferable salt in acute or subacute exacerbation occurring in the subjects of malarial cachexia.

II. That in cases where the patient is much run down and exposed to unsanitary conditions, iron should be part of the medicinal treatment.

III. That where the most prominent symptoms are connected with the nervous system, including apparent pulmonary, cardiac, intestinal, or gastric troubles, arsenic is indicated.

IV. That where the most prominent symptoms are rheumatoid or myalgic in character, salicin, or some of its derivatives or compounds, is of advantage; cinchonidine salicylate, by preference, in order to obtain the anti-malarial virtues of the cinchona alkaloid. Cinchonidine salicylate is also of use in maintaining an effect produced by quinine after the withdrawal of that drug, and is superior to quinine where the paroxysmal manifestations are vague and irregular.

V. That iodine is of some benefit when administered alone, and of decided benefit when combined with other remedies.

*THERAPEUTICS OF FEMALE STERILITY.*

From the advance sheets of the still unpublished book of PROF. KISCH (Prague-Marienbad), entitled "Sterility of Women," we abstract its therapeutical views, and present them to our readers in a condensed form.

The therapeutics of female sterility has as its object the removal of such causes as have brought about this pathological condition. But this testifies at once to the difficulty and uncertainty of the therapeutic interferences.

The first step toward a cure of this defect is a scrupulous and minute anamnesis of the genital and marital relations not only of the wife but also of the husband, provided such be possible. We have to consider the sexual development of the woman, the age of her maturity, and naturity of menses, with all details. We have to search for a scrofulous, syphilitic, or other hereditary taint, to inquire as to her past state of health, diseases of childhood, and the history of her family and relations, especially in view of an absent or scanty procreative ability. The delicate questions concerning the coitus, its relations, nature, and consequences, can unfortunately be not avoided. It is necessary for the physician to know whether it occasioned pain or the normal gratification, whether the introduction of the penis into the destined parts is impeded or not, and whether the sperma rapidly flows out again from the vagina. (A case is reported to Kisch where a lady consulted him for her sterility, which was afterwards traced to a condom used by the husband without her knowledge.) If possible, the sperma of the husband is to be examined microscopically. It is gathered in a condom, and brought for inspection immediately after the coitus. Several drops of vaginal or cervical mucus are likewise taken from the parts immediately after a coitus, the sperma placed in it, and the possible influence of the female secretions on the male noted. Occasionally we observe numerous spermatozooids moving to and fro in the semen; but, when placed in the secretion of the female genitals, they lose at once their mobility. This of course shows that the *materia peccans* in this instance does not rest with the man. Some men object to the examination of their semen as an insult; they regard *potentia cœundi* as identical with *potentia generandi*.

We have to find out whether germ-formation is impeded, or whether inherited or constitutional alterations are present in the ovulum, which render the same unimpregnable. Besides, we have to search for organic affec-

tions of the ovaries or their neighborhood, which either prevent the formation or the descendance of the egg. The tubes or the cervix may be at fault on account of a congenital or acquired narrowness. Perhaps the secretions of the vagina are morbidly affected, so as to render the sperma inert. Numerous other questions of this kind are all deserving of our consideration, and we see that only by the most careful and minute scrutiny is it possible to reveal, of the numerous possible causes, the reason of the sterility in a given case.

Sims's assertion that the cure of sterility can only be accomplished by surgical interference is untenable. The principal factor is a medication which raises the nutrition of the entire organism, improves the blood-formation, and favors the resorption of pathological products in the sexual organs. For in a large majority of cases presented for treatment we have to deal with anæmia, chlorosis, and scrofulosis. Local alterations in the parts of course require their rectification, such as the various forms of flexion and version. Occasionally surgical interference is called for in cases of abnormal conditions of the hymen, or of abnormal communications between vagina and neighboring organs, or, finally, on account of neoplasms.

The prophylaxis of sterility deserves the fullest attention of every practitioner. The first requisite, of course, is a complete sexual maturity in both the husband and wife, which, as everybody knows, is not always the case at the present day, especially in so-called high life.\* Another important factor is the avoidance of marrying relatives. The results of this principle, as practised for centuries among the Spanish nobility, are too well known to require any illustration. In certain savage races, on the other hand, the exogamic principle—*i.e.*, to marry only women from another tribe—is strictly observed. Next in importance as prophylactic measures stand proper diet, regimen, and occupation of the girl, especially during the period of menstruation, and, in case of a married woman, additional prudence in her confinement. Jumping, dancing, riding on horseback or in sleigh, often lead to inflammations of ovaries, peritoneum, and pelvic connective tissue, especially during menstruation, with the ultimate result of sterility. There are girls who for modesty's sake

\* This recalls the instance of the successor to a European empire, who, marrying the daughter of a European king, found that for a whole year his wife had not yet menstruated.

do not wish to acknowledge their menstrual indisposition when asked to join in a dance or sleigh-ride, and who after a while pay a severe penalty for their misplaced bashfulness. That masturbation also enters to a certain extent into the causes productive of sterility seems very plausible, though, of course, definite information in this direction is wanting. In some instances the fault lies with a deficient involution of the uterus subsequent to a confinement, while uterine catarrhs and residual exudations are to blame in other cases. Indeed, metritis has been occasionally produced by venereal excesses of husband and wife, so that even in this direction precautions are not out of place.

In conclusion, Kisch advises every mother to fully instruct her daughter previous to an intended marriage of her future duties, and to give her such admonitions as will lessen or remove the chances of a future sterility.

#### INFANT FEEDING.

At the meeting of the Medical Society of the State of New York, held February 3, 1886, DR. E. F. BRUSH, of Mount Vernon, read a paper with this title, and pointed out some simple methods of feeding an infant when it had been deprived of the breast (*New York Med. Journ.*, February 6, 1886). He urged the value of simple foods in preference to the so-called "patent foods," the composition of which was often unknown. He had examined the composition of the once famous "Liebig's food for infants," and of another popular food, and indicated the dangerous amount of alkali contained in them, citing Dr. Jacobi's warning that "we are not very careful in doses of alkalies in general," and Dr. Stillé's remark that alkaline treatment "lessens the amount of fibrin in the blood." He showed by the figures furnished by one of the advocates of peptonized food that the results of such feeding were not satisfactory. Proceeding, then, to the immediate subject of his paper, he stated that one of the greatest elements of failure in the artificial feeding of infants was the desire to give one sort of food alone under all circumstances, and hence the blind prescription of patent foods. He advised, on the contrary, the preparation of foods from simple articles to meet the requirements of each case as it arose. When with food thus prepared there was a failure, the physician at least knew what the failure arose from. Commencing, then, with the child at birth, the

author gave his formula for the best substitute for colostrum, and his further treatment of the cathartic effect was either excessive or defective. He then discussed the question of the best staple food. He had no hesitation in saying that it was cow's milk, which, however, was subject to many conditions that rendered it unfit, unless due care was exercised. In 1879 he had pointed out the difference between the milk of the ruminant and non-ruminant animals as regarded particularly the quantity and quality of the casein contained in them, and the difficulty experienced by infants in digesting a milk intended for calves. When an infant vomited a hard curd, the indications were that the milk must either be prevented from coagulating in the stomach or coagulated and broken up before entering the stomach. He showed that it was inadvisable to use an alkali, and therefore preferred the latter course, that of coagulating and breaking up the milk before giving it. In other cases he recommended the addition of lime-water as the safest agent, as it did not, like other alkalies, keep the stomach in an alkaline condition, nor cause an acid condition of the intestines. In case of diarrhoea in children fed on milk, the indications were to stop the milk immediately. The milk was usually the cause of the trouble, and it was rendered unfit by the physical condition of the cow, such as rutting, gestation, the ingestion of poisonous herbs, cruel treatment, and the like, to all of which states many cases of diarrhoea in infants could be traced. In these cases of diarrhoea he recommended oatmeal-water, which his analysis had convinced him was somewhat similar to milk in composition. He insisted on the necessity of the medical attendant himself preparing or teaching the preparation of these simple foods. In all cases the child should be put back on its ordinary milk diet as soon as possible. As to the kind of cow best adapted to supply milk, he preferred the common-grade cow to the Jersey or fancy breeds. The latter were of a tuberculous tendency, the fat in the milk was not sufficiently emulsified, and they were of an excessively nervous temperament, while the common cow ordinarily was gentler and a good feeder. She should always be stall-fed. When milk was bought, that of one cow should always be avoided. In cases of constipation, raw malt-water, carefully prepared as a diluent of the milk, was efficacious.

DR. JACOBI said that the tendency of cow's milk to coagulate in a very hard curd could be overcome by a method which he had some

years ago learned from Dr. Loomis. It consisted in adding half a teaspoonful of dilute muriatic acid to a pint of water, mixing this with a quart of milk, and then boiling. The taste was pleasant, and coagulation would take place in fine particles, as in woman's milk.

#### THE REMOVAL OF SUPERFLUOUS HAIR BY ELECTROLYSIS.

Among the various methods adopted for the removal of superfluous hair there are none so easy of performance, so painless in their operation, so certain in their destruction of the hair-papilla, and which leaves fewer traces of an operation on the surface of the skin than electrolysis. Dr. Mechel, the oculist of the Missouri College, first introduced the operation for the treatment of trichiasis. To Drs. Hardaway, of St. Louis, White, of Boston, and Piffard, of New York, we are indebted for the introduction and popularization of electrolysis as a method of destroying hair.

MR. GILBERT SMITH (*Brit. Med. Journ.*, January 23, 1886) adds his testimony to this, and states that in his hands in all cases this mode of treatment has been most successful, and that he has had an opportunity of examining some patients six months after the removal of hair, and has found that there has been no return of the growth.

The apparatus required for the operation consists of a galvanic battery of from ten to fifteen cells, a sponge electrode, a No. 14 needle, an electrode needle-holder, and two cord conductors, each a yard in length.

The needle, properly fixed in its holder, is connected with the negative, and the sponge with the positive, pole of the battery. The needle is carefully introduced into the follicle alongside the hair, which is used as a guide to the papilla, the moistened sponge-electrode being grasped in the patient's hand (the needle should be applied before the circuit is completed by the sponge electrode, and the converse after the operation,—that is, the sponge-electrode should be released before the needle is withdrawn, otherwise pain will be caused).

The needle is held in position from ten to thirty seconds, according to the size of the hair, until slight frothing is produced, or a wheal appears around the mouth of the follicle; the sponge-electrode is then loosened and the needle withdrawn.

The hair should now be removed, and the

ease with which it is extracted indicates the completeness of the operation. If the hair does not leave the follicle with the feeblest traction, the needle should be reintroduced one or more times. Shortly afterwards slight redness and swelling are perceptible.

Under a strong lens it is not difficult to introduce the needle directly into the follicle; but this is not absolutely necessary, as the requisite destruction occurs if the instrument be in its immediate neighborhood.

In a few hours the circumscribed congestion disappears, leaving small papules and pustules at the point of operation, which may remain visible for some weeks. For this reason, where the hairs are numerous, as upon the upper lip, not more than twelve should be removed at a sitting, leaving an interval of a week or two between each operation. Where there are but few hairs upon the less prominent regions, all of them may be removed at one sitting; although it may be remarked that the tediousness of the process soon tells upon the operator.

Minute scars are most apt to occur where it has been found necessary to introduce the needle into the same follicle a number of times, or where hairs situated closely together are removed at one time; but even the most marked cicatrices are scarcely noticeable after the first few weeks.

Like all operations of a delicate nature, this requires a certain amount of skill and manual dexterity, only to be acquired by some experience in its performance; this, however, is easily gained.

The amount of pain felt differs in different patients, varying according to the region attacked or the sensitiveness of the patient; while it is not trivial, it is not unbearable, and a tolerance seems to be established after a few sittings.

#### HYPODERMIC USE OF THE BLACK AND RED OXIDE OF MERCURY.

DR. WATRASZEWSKI, of Warsaw, has used calomel injection in syphilis for about two years, but feels, according to his statement in the *Centralblatt für die Med. Wiss.* (January 9, 1886), little satisfied with the results obtained. In the majority of instances he noted after three injections considerable local and constitutional disturbance, such as lassitude, weakness, and diarrhoea, besides ischiatic pains, swelling and abscesses in the gluteal region, where the injection was made. These objections to the calomel injections induced

Dr. Watraszewski to try other preparations of mercury. He found that both the red and the black (hydrated) oxides of mercury proved less objectionable, and that employed in doses of about 1 grain (in suspension in water or gum arabic) hypodermically they demonstrated a prompt specific power. Two to five injections are quite sufficient, and it is well to allow of an interval of six to eight days between the single injections. Although Watraszewski has made over two hundred of these injections, he never observed any unfavorable secondary effects following them. Pain was little or not at all complained of, and abscesses were never observed. The black oxide appears to act somewhat more mildly than the red oxide, though in their general effects they are quite interchangeable. Our author claims to have obtained satisfactory results with these preparations of mercury not only in the initial stages of the syphilitic infection, but also in its so-called tertiary forms.

#### A NEW TREATMENT FOR FRACTURED OLECRANON.

DR. CLAYTON PARKHILL (*Denver Med. Times*, January 23, 1886) recommends as a method of treating fractured olecranon that the fractured surface be denuded, by a subcutaneous operation, of all ligamentous or fibroid cartilaginous tissue that may have formed. For this purpose he recommends an instrument with a blade similar in size and shape to a tenotome, but having a double edge, bent at an angle of forty-five degrees with the shaft. The skin should be punctured at one side of the line of fracture, making a valve wound. A curved canulated needle, threaded with strong silver wire, is introduced at this opening, and carried as close to the bone as possible, so as to include, if it be to the distal side of the fracture-line, the fibres of origin of the forearm muscles and the periosteum. Crossing the gap between the fragments, let the instrument emerge on its opposite side, at a point corresponding to that of entrance. Leaving the wire in position, withdraw the needle. After being again threaded, let it be re-entered at the point of exit, and carried across the opposite fragment, including the fibres of insertion of the triceps and the periosteum, to emerge at the first point of puncture. When the needle is removed, it will be observed that the four ends of the wires issue from the two points of puncture. The amount of soft tissue included by

the wires must vary with the case and the judgment of the operator. A careful examination should be made to see that the ulnar nerve is not within the tissue surrounded. By twisting the corresponding ends of wire, the fragments will be brought into apposition. If desirable, the ends may be cut close and allowed to disappear, thus making the ligature wholly subcutaneous. One wire might be used after the manner of ligating a varicocele; but should it be desirable, either after the cure is completed, or at any other time, to remove it, it will be found that two wires can be taken out with less pain to the patient and greater ease to the operator than one.

A certain amount of inflammation will be engendered by the ligature, but probably not more than will be necessary to the process of cure. Should it be excessive, however, circumstances will be most favorable for its control.

An anterior splint should be used, holding the arm in a slightly flexed position.

This operation was at first intended only for ununited fractures. Statistics show such a small proportion of cases in which bony union has taken place, that it becomes a question whether it is not a proper method of procedure in recent fractures.

The writer offers the above simply as a suggestion to the profession. While he has not had an opportunity of testing its efficiency, he believes that it combines all the desirable points of the received operations and avoids their dangers.

#### QUILLAJA SAPONARIA AS AN EXPECTORANT.

We have already in a previous number referred to Kobert's proposition as to the substitution of quillaja bark for senega, and Dr. F. GOLDSCHMIDT reports in the *Zeitsch. für Ther.*, December 15, 1885, the results of a series of experiments which have been made with this drug. The mode of administration was to make a decoction of 75 grains of the bark in 4 ounces of water, to which 5 drachms of syrup may be added. Of this mixture a tablespoonful may be given every hour. Quillaja was employed in thirty cases, invariably with favorable results in cases where the expectoration was difficult, such as in high degrees of emphysema, dilatation of the bronchi, and chronic bronchial catarrh. After the use of quillaja the expectoration always became more copious and easier and the respiration freer. It therefore appears that quillaja possesses the power, in a very marked degree, of

rendering expectoration easier. Contrasted with the other expectorants, it is well known that the ammonia alkalies, apomorphine and ipecac, when employed for any length of time, nearly always occasion such marked digestive disturbance as to entirely prevent their use. Senega, in its mode of action, and in the results which it produces, is closely comparable to quillaja. Both are able to start suppressed secretion, and to aid the removal of it when profuse. The advantages of quillaja over senega have already been alluded to. The mode of action of quillaja appears to be two-fold. It not only increases the vigor of the cough, and so facilitates the removal of secretion, but it also renders the secretion more fluid, and so enables its removal with greater readiness.

#### PERMANENT DRAINAGE IN ASCITES.

At the recent meeting of the New York Academy of Medicine, DR. AUGUSTUS G. CAILLÉ related the history of two cases (*Philadelphia Med. Times*, February 20, 1886) illustrative of the value of permanent drainage in the treatment of ascites. About four years ago he saw an elderly gentleman suffering from cirrhosis of the liver, in whom the symptoms depending upon ascites were so marked as urgently to demand tapping and repetition of the operation. He was tapped nine times in the course of seven months, a pailful of serum being removed each time. Before the tenth operation Dr. Caillé determined to attempt permanent drainage, although the danger of exciting a peritonitis or other serious complication was fully appreciated. An incision an inch in length was made in the median line half-way between the umbilicus and symphysis pubis, a trocar and canula introduced, the trocar withdrawn, and a rubber tube inserted. After withdrawal of the fluid the tube was allowed to remain, iodoform being put upon the dressing at the mouth of the tube, and the fluid allowed to drain and be absorbed by towels. Some eczema developed under the dressing, which disappeared under suitable management. After drainage had been established the œdema disappeared rapidly, the heart-action improved, the breathing was freer, the troublesome cough disappeared, the bowels became regular, the appetite improved, and the patient became able to go about, wearing all the while the tube. The rubber canula remained *in situ* about nine weeks, when it was removed, and at the end of another four weeks the opening

closed. The patient was able to be about his duties for nine months, there being no return of the œdema or of the ascites. After nine months his strength began to fail, and he finally died of heart-failure. Two weeks before death there was a return of slight œdema of the ankles. At the autopsy cirrhosis of the liver and fatty heart were found. Careful inspection of the peritoneum at the seat of puncture revealed no evidence of inflammation.

The second case was similar, and in addition there was marked purpura hæmorrhagica, epistaxis, bleeding gums. The patient had no appetite, and was unable to sleep. He was treated as was the other patient,—in this case a rubber tube being employed to conduct the drainage from the rubber canula to a bucket by the bed containing a carbolic solution. The tube was worn for seven weeks. The ascites and œdema disappeared. The appetite improved. There was, in short, improvement in all the symptoms. The patient was able to pass ten weeks with his family in the Catskills, and continued to live a comfortable existence until the spring of 1885, when he died suddenly, as was supposed of heart-failure, when attempting to get out of bed. There was no return of the ascites. An autopsy was not allowed.

In his general remarks Dr. Caillé considered four questions :

1. What are the symptoms and dangerous mechanical effects of ascites ?
2. How is the collateral circulation established in cirrhosis of the liver ?
3. Will the absence of intra-abdominal pressure or pressure from ascites promote collateral circulation and functional activity of important organs, and thereby prolong life and add to the comfort of the patient ?
4. How is drainage best accomplished ?

After considering these questions, the author said he was inclined to believe from this limited experience that we need not fear peritonitis so much when ascites is present as under other circumstances. Too much importance, however, should not be attached to these two cases, for the number was too small to judge from them of the value of this procedure. It was the author's opinion, however, that it should be given a trial in cases of ascites which required two or more tapplings for re-accumulation of fluid.

The PRESIDENT said it appeared to him that what Dr. Caillé had done in these two cases was what might have occurred spontaneously. Probably some of the gentlemen present had

seen cases of extreme ascites in which spontaneous rupture of the abdominal walls had taken place. He had seen some such cases. The place of rupture was usually in the median line, particularly at the umbilicus. In such cases there was, of course, a permanent fistula established, and, instead of allowing it to occur at a spot which was not convenient or pleasant, he thought it was better for the surgeon to make the opening where he wished it should be established. There was such a case in the German Hospital the past year,—that of a heavy German, in whom spontaneous rupture took place at the umbilicus, allowing of the escape of the ascitic fluid. It healed and reopened several times in the course of a few months. The patient felt so well satisfied with his condition that he left the hospital, but naturally the shrinking liver and swelling spleen still remained.

The President then described a case of encysted ascitic fluid which occurred in his ward in the Bellevue Hospital last year, in which the physical signs were almost exactly those seen in a patient, over twenty years ago. In the case seen long ago he made the diagnosis of ovarian tumor, and, although post-mortem examination proved his error, he still thought that the diagnosis of ovarian cyst was the only one justified by the signs during life. He had this case in mind when contemplating an operation upon the patient in Bellevue Hospital, yet the signs were so plainly those of an ovarian cyst that an incision was made, when it was found that the fluid was ascitic, limited by adhesions. Permanent drainage was then established for a time, and the patient improved and left the hospital. He had since heard that the fluid had reaccumulated. There was a family history of tuberculosis, and it was probable she had tubercular peritonitis.

Since learning of Dr. Caillé's operation, Dr. JACOBI had performed it upon a man suffering from cirrhosis of the liver, with jaundice, purpura, epistaxis, loss of strength, ascites, dyspnoea, etc. As his strength was constantly diminishing, and the symptoms demanded relief, he established permanent drainage midway between the umbilicus and urinary bladder in the manner described by Dr. Caillé, leaving the tube in several weeks,—until the patient's death, for he had been dying for some time. The canula was obstructed by wax during the night, drainage being continued only during the day. The patient felt relieved. Post-mortem examination revealed no peritonitis. Dr. Jacobi thought the operation of Dr. Caillé a good one, and he would

repeat it whenever a suitable case came under his observation.

The question of medicinal treatment of cirrhosis of the liver having been raised, the President said that small doses of corrosive sublimate, long continued, were beneficial in all forms of interstitial inflammation, whether in the form of a myelitis, a nephritis, or a hepatitis. Of course when the disease was advanced its progress could not be stopped, but when only a portion of an organ was involved this treatment might enable us to prolong the patient's life indefinitely.

#### MENINGITIS AFTER EXCISION OF THE EYEBALL.

At the meeting of the Ophthalmological Society of the United Kingdom, held January 28, 1886, Mr. E. NETTLESHIP (*Brit. Med. Journ.*, February 6, 1886) read a paper, based on the case (at the Moorfields Hospital, in July, 1885) of a young man who was operated upon unsuccessfully for dislocation of the lens into the anterior chamber. The eye was excised in a state of early, but violent, suppurative inflammation, seventy-two hours after the attempted removal of the lens. The orbit was irrigated with a very weak solution of biniodide of mercury. The man became restless and excitable, with high temperature, within forty-eight hours, and died seventy-five hours after the incision. He was attended by Dr. Stephen Mackenzie. Purulent meningitis was found at the base, and between the cerebrum and cerebellum; there were no tubercles. It was remarkable that well-marked tough thickening of the pia mater, and firm adhesion of the opposite edges of the longitudinal and Sylvian fissures, were found, undoubtedly indicating a previous attack of general meningitis, but the early history of the patient was almost negative. Mr. Nettleship had tabulated all the other cases of meningitis after excision of the eye, twenty-nine in number. No cases were included in which it was known that the operation was complicated by injury or disease of the walls of the orbit. Of the thirty cases, twenty-six were fatal, and eighteen of these were examined after death, and meningitis found in all; the remaining four cases recovered, usually after a long and severe illness. In a considerable majority, the meningitic symptoms set in within forty-eight hours of the enucleation, but the duration of the illness, when fatal, varied more than the period of onset. Except that the meningitis usually affected the

base, and was sometimes more marked towards the front and on the side of the excised eye, and that twice there was thrombosis of the cavernous sinus, there was very little macroscopic evidence of transmission from the orbit; but microscopic examination in four cases showed inflammation in or around the optic nerve, and in one inflammation and micro-organisms in the sixth nerve. It is suggested that, in spite of the rarity of visible thrombosis, the veins may in some cases be the carriers, and that (owing to the numerous anastomoses) the blood-current in the cerebral veins might sometimes be reversed, allowing septic material to pass from the orbit upwards to the brain, instead of into the jugular vein. In some cases only the convexity was affected, and in others the disease was more marked on the side opposite to the excision. In a considerable majority, the excised eye had been wounded; but the author dissented from Von Gräfe's statement (1863) that the risk of meningitis was much greater if the eye were suppurating when excised, since it appeared that in exactly half of the cases no visible suppuration was going on, or had occurred, in the lost eye. The disease was probably due to infection of the orbital wound, either by the decomposition of discharge pent up by tight bandaging, or (as was probable in two cases) to erysipelas. Complications were present in a few cases. Mr. Nettleship believed that with care the cases might be rendered even much more rare than they had hitherto been, especially by providing free drainage from the orbit when there was much inflammatory swelling. He at present preferred excision, with suitable precautions, in all cases, to evisceration, as it had not yet been proved that the latter operation might not cause sympathetic disease. Only four cases of meningitis following other operations upon the eyeball were known, and in only one was a post-mortem examination made. In certain cases of meningitis after excision, sympathetic inflammation had set in some time before the meningitis, a fact which seemed to militate against the theory that sympathetic disease passed from the exciting to the sympathizing eye by the meningeal coverings of the optic nerve.

#### THE DIGESTION OF MILK.

DR. M. REICHMANN draws the following conclusions from a number of elaborate experiments as to the digestibility of milk in the

human stomach (*Deutsche Med. Zeitung*, No. 82, 1885):

*First.*—Boiled milk leaves the healthy stomach more rapidly than an equal quantity of unboiled milk.

*Second.*—The digestion of boiled milk is more rapidly accomplished than that of unboiled milk.

*Third.*—The coagulation of unboiled milk in the stomach is complete in five minutes.

*Fourth.*—This coagulation is not caused by the acid of the gastric juice, but by the influence of a special ferment (milk-curdling ferment).

*Fifth.*—The acidity of the gastric juice is at first due almost solely to lactic acid, and, later in the process of digestion, to the presence of hydrochloric acid.

*Sixth.*—Hydrochloric acid first appears in perceptible amount forty-five minutes after the ingestion of half a pint of milk.

*Seventh.*—For the first hour and a quarter after the ingestion of milk the acidity gradually increases, and then decreases, until the milk has entirely left the stomach.

*Eighth.*—The curds of casein in digestion of boiled milk are much softer than in the digestion of uncooked milk.

#### INDICATIONS FOR OPENING THE MASTOID PROCESSES.

DR. A. R. BAKER (*Cleveland Med. Gazette*, February, 1886) publishes the following summary as to the most recently stated indications for opening the mastoid processes in cases of purulent disease of the middle ear:

1. Purulent inflammation in the mastoid process appearing in the course of suppuration of the middle ear when persistent severe pain in the bone cannot be subdued by the application of the ice-bag, leeches, or by Wilds's incision (Schwartz).

2. Painful inflammation in the mastoid process occurring in acute and chronic suppuration of the middle ear, in consequence of growths filling up the external meatus or the tympanic cavity. When attempts to remove the obstacle to the free escape of pus have failed, the operation is imperative (Grünig). The operation is indicated even though the soft parts over the mastoid are not swollen or infiltrated (Politzer).

3. When the posterior superior wall of the meatus is bulging, and when, after incision, the abscess is not emptied and the symptoms of retention of pus continue (Toynbee, Du-play).

4. Persistent pain and tenderness in the mastoid process, lasting for days or weeks, in which there is probably an osseous abscess not communicating with the tympanic cavity (Politzer).

5. In every suppuration of the middle ear, combined with inflammation of the mastoid process, in which fever, vertigo, and headache are developed during the course of the affection, which may indicate a dangerous complication. In such cases the indication for the operation is vital (Politzer, Roosa, Buck).

#### A SIMPLE METHOD FOR THE TREATMENT OF CHRONIC UTERINE CATARRH.

DR. KUGELMANN (*Zeitsch. für Ther.*, No. 21, 1885) states that he has frequently obtained relief in nasal catarrh through the inhalation as a snuff of finely-powdered iodoform deodorized with Calabar bean, and this success led him to the employment of iodoform, blown into the uterus, as a treatment of chronic catarrh of that organ. The vagina is first washed out with water, then with three per cent. carbolic acid, and then dried with cotton. A male catheter is then filled with the proper amount of iodoform, and, after being suitably curved, is introduced into the uterus, and the powder blown out by means of a rubber bulb, which may be readily attached to the end of the catheter. In the removal of the catheter, care must be taken not to allow the bulb to expand until the catheter is entirely withdrawn, otherwise the powder will of course be sucked again from the cavity of the uterus into the catheter. The only precaution necessary is to have the catheter entirely dried, otherwise the powder will of course stick to the tube and cannot be blown out. The process may be repeated twice weekly. Dr. Kugelman states that he has invariably been satisfied with the results.

#### THE TREATMENT OF GONORRHOEA.

Though the treatment of gonorrhœa has unquestionably undergone a great change for the better during the last few years (as shown by the less frequent occurrence of stricture, orchitis, bubo, etc.), it is by no means certain we have arrived at the best method of dealing with it. In the incubative stage, injections of nitrate of silver have been for the most part abandoned, and it is now pretty well agreed that the more mild and soothing the

treatment is at this as well as during the acute period, the more likely is it to bring the case to a satisfactory termination. If any injection is used at all, it should consist simply of warm water or a very weak solution of permanganate of potassium or boric acid. Mr. Watson Cheyne has of late been employing bougies of eucalyptus and iodoform, injections of sulpho-carbolate of zinc (gr. ii to the ounce of water) and copaiba internally, apparently with good effect, though Dr. F. P. ATKINSON (*Practitioner*, February, 1886) believes that this form of treatment is more suitable to the third stage of the disorder. Effervescing citrate of potassium administered internally is of great use in lessening the general febrile condition, the pain in passing water, and also the tendency to orchitis and bubo. The patient should take a light nourishing diet, such as milk, barley-water, soup, broth, and light puddings, with bread-and-butter, toast, and biscuits. All stimulating alcoholic drinks, condiments, and coffee should be avoided.

In the third stage, when the sense of scalding has passed away, Dr. Atkinson generally orders some copaiba, or oil of sandalwood capsules, or Cleret's *copahine mège* sweetmeats. If the discharge is not lessened by this treatment, then injections of sulphate of zinc (gr. iii), sulpho-carbolate of zinc (gr. ii), or permanganate of potassium (gr. i) to the ounce of water, or Watson Cheyne's bougies will often prove of great benefit. If, however, these do not seem to effect the desired purpose, then the best thing is to inject into the membranous portion of the urethra (which will generally be found to be painful when reached) a solution of nitrate of silver (containing from two to five grains to the ounce) by means of Erichsen's liquid caustic catheter. Two or three drops only are ejected by this means, but this quantity is quite sufficient to stop the discharge, and it rarely, if ever, requires to be repeated more than two or three times at intervals of from five to seven days. Some persistent cases of gleet have come under Dr. Atkinson's care which have readily yielded to this treatment, and it seems certain that ordinary injections do not reach the real seat of the mischief.

#### COCAINE IN THE TREATMENT OF HYPOPION.

MR. GUNPUT SING states in the *Indian Med. Gazette*, December, 1885, that a woman suffering from keratitis and hypopion in both

eyes came under his care, in whom, on account of the great pain and photophobia from which she was suffering, his assistant put a two per cent. solution in both eyes and told her to wait. When examined a short time afterwards, it was found that the hypopion of the left eye had disappeared, and that in the right eye was greatly diminished. Being doubtful as to whether this relief of the hypopion was really due to the instillation of cocaine, he tried it in several other cases, and found that the drug invariably caused the disappearance of hypopion when of at all recent formation. When of longer standing it greatly diminishes their size, but generally some inspissated matter remains over which it does not have any power, and this is removed by tapping. In two cases the hypopion again formed in two days, but cocaine again dispersed it speedily, and it did not again appear. In some cases only two hours are required for the complete dispersion of the hypopion.

#### RESEARCHES ON THE MALARIAL INFECTION.

The Italian physicians have at all times evinced a lively interest in the study of the malarial infection, which in no country possibly assumes a more malignant and at the same time domestic type than in their own. The investigations of Crudeli and Tomasi on the parasitic cause of malaria, instituted and published some two years ago, will be recalled by many of our readers. At present we have before us some further observations in the same direction by PROF. MARCHIAFARA and DR. CELLI, which appear to solve the mystic problem of the cause of this affection (vide *Deutsche Medicinal Zeitung*, January 25, 1886). We content ourselves with rendering the principal results of their observations, as follows:

1. In the blood of every person suffering from malarial fever we find enclosed in the red blood-corpuscles peculiar microbes, consisting of homogeneous protoplasmic particles, endowed with a very lively amœboid movement. These microbes allow of a distinct coloration, and occur only in this affection; they were termed by the authors "plasmodies or hæmoplasmodies of malaria."

2. In the interior of these microbes we often find a red or black pigment (melanine), which, however, is no integral portion of theirs, but is obtained from transformation of hæmoglobin, which the parasites have abstracted from the red blood-corpuscles.

3. If this production of pigment has taken place, we have malaria with melanæmia, if not, malaria without melanæmia. This refers also to the grave cases of a pernicious or fatal nature.

4. The parasites propagate themselves by the process of fissure.

5. Intravenous injection of malarial blood produces malaria in a previously healthy person.

6. The plasmodies increase in number with the progress of the malarial infection, and decrease with the regression of the symptoms under cinchonization.

#### OPERATIVE TREATMENT OF POPLITEAL ANEURISM.

There are now few surgeons who, when called upon to treat a case of uncomplicated and limited popliteal aneurism, do not first try the treatment of it by some form of compression. When compression fails to cure popliteal aneurism, or when the case is one unsuitable for it, the treatment most invariably suggested in practice is ligation of the femoral artery at the apex of Scarpa's triangle. Should ligature of the femoral artery fail to cure the disease, or should pulsation of the sac return and persist after this operation, the usual advice in practice is to try compression above the seat of ligature, or to try the flexion method, or, these failing, to tie the external iliac or common femoral arteries. Should all these methods fail, there only remains the choice between amputation and opening the sac, and the general opinion of surgeons is that amputation gives the most favorable chance to the patient. The old operation of laying open the sac and securing the artery at the point of communication with it is occasionally referred to by authors, but it is certainly not advocated in the case of popliteal aneurism. MR. THOMAS ANNANDALE (*Edinburgh Med. Journal*, February, 1886), while advocating the treatment of popliteal aneurism by some form of compression in suitable cases, and, this failing, by ligature of the femoral artery, believes that the old operation has been heretofore too much ignored by surgeons, and that in certain cases of this disease it should be used until proof is advanced of a safer proceeding than those methods which are usually adopted, and that the antiseptic ligature and dressing in this operation is now a very simple proceeding in properly selected cases, provided the circulation in the sac can be checked during the

operation; and this, in a case of popliteal aneurism, is always possible. His method of operation is to open the aneurismal sac and remove all clots; a bougie is then inserted into the opening of the artery, and passed along the canal of the vessel upon its cardiac aspect; two small incisions are then made in the wall of the sac immediately above this opening; the aneurism-needle is then passed through these incisions and under the artery. A ligature is then drawn through by means of the aneurism-needle, and tied around the vessel upon the bougie, the latter being gradually withdrawn as the ligature is tightened. The same proceeding is carried out upon the distal end of the artery, the bougie being inserted again and passed downwards.

Mr. Annandale reports a case of popliteal aneurism which was successfully treated by this method. He also alludes to two other successful cases treated by this plan, and refers to them in support of the opinion that the old operation is to be preferred to ligature of the femoral artery in Scarpa's triangle in the following conditions of popliteal aneurism:

1. In cases of large aneurism filling up the space and interfering by pressure with the venous and other circulation of the limb below, or causing serious nerve-pressure.
2. In rapidly-growing aneurisms which have attained some size.
3. In ruptured and diffused aneurisms.
4. In aneurisms which have involved the knee-joint by pressure.
5. In aneurisms attacked with inflammation and suppuration.
6. In aneurisms which the ligature of the femoral artery and compression have failed to cure.
7. In arterio-venous and other aneurisms of traumatic origin.
8. In cases of general arterial disease, provided surgical interference is considered necessary or advisable.

In such of these conditions which are of an acute nature there must be no delay in performing the operation; and should symptoms of gangrene already be present in any case, amputation is the rule.

#### PHYSIOLOGICAL ACTION OF ISOCICUTINE.

We abstract from the *Comptes Rendus* (vol. c. p. 806) the following points on the action of isocicutine from a paper of Dr. ROCHEFONTAINE. The drug is chemically considered the hexahydrate of  $\beta$ -collidine, and isomeric with

cicutine. It is prepared synthetically, and is practically an alkaloid. On frogs its action is similar to that of curare; it paralyzes first the spinal cord and medulla oblongata, then it destroys the excitability of the motor nerves and muscles, and ultimately produces cardiac failure. Warm-blooded animals put under the influence of the drug perish under symptoms of general weakness and respiratory paralysis. It remains to be seen whether this drug, which, to judge from the above experiments, possesses a very distinct and powerful physiological action, can be utilized for therapeutic purposes.

#### THE TREATMENT OF MALARIAL FEVERS WITH TINCTURE OF IODINE.

MR. W. E. HENDRICKS states in the *Indian Med. Gazette*, December, 1885, that since the 15th of April last he has treated fifty cases of malarial fever with iodine. He believes that the iodine constitutes an efficient and cheap substitute for quinine. He has tried not only quinine but all the alkaloids, and arsenic as well, and in one or two cases he claims that more beneficial effects were derived from iodine than from quinine. Its use has been followed by no bad results. He was first induced to try the effects of iodine internally in a case of tertian ague with congested spleen of enormous size; with the thought that instead of applying the tincture externally, which after a period of sixteen years he had found almost useless, perhaps better results might be obtained by internal administration. For this purpose 5 minims each of the iodine and iron tinctures were given in an ounce of water twice daily, and after continuing this treatment for six days the fever that before then had come on regularly every day for three months quite disappeared, and the spleen began to diminish in size. The case remained under treatment for one month; up to which time the fever never returned, although the spleen still remained slightly enlarged. Of the fifty cases treated he states that there has been no return of fever as yet, though some of the cases were treated as long as six months ago: the average retention of the patient on the sick-list so treated was only 4.3 days. In only one case had he to increase the dose of iodine from 5 to 10 minims, the former quantity not being sufficient to produce complete recovery, although the duration of the fever was cut short from three to six hours. Headaches as the result of malaria have also been successfully treated by this drug.

*JABORANDI AS A GALACTAGOGUE.*

There is a decided difference of opinion among therapeutists as to the effect of jaborandi upon the mammary gland. Some claim that it is without effect; others insist that its use produces an increase in the secretion of milk. DR. H. LOWMAN (*Cleveland Med. Gazette*, February, 1886) reports notes of four cases in which the fluid extract of jaborandi appeared to act as a galactagogue in the recent puerperal state. In the first case, a multipara of 35 years of age, the secretion of milk commenced to fail two weeks after delivery until not one-third the average quantity was produced. The fluid extract of jaborandi was then given in doses of 8 minims every three hours. On the second day of the administration of the drug the milk increased in quantity. By the third day it had increased still more, so that the child had nourishment from the mother sufficient to satisfy it. Increased salivary and cutaneous secretions led to the discontinuance of the drug; but the milk flowed in good quantities for eight days and then rapidly diminished. Jaborandi was then used, and increase of the milk was again noted. It is, however, worthy of note in this case that the mother's health underwent a great change for the better during the time the jaborandi was given. Iron, quinine, and mineral acids were given, and the nourishment of the mother was pushed as much as possible; so it is very questionable whether the use of the jaborandi and the temporary increase of the milk-secretion were more than coincidental. That, however, the jaborandi exerted a certain amount of influence upon the secretion seems to be proved by three other cases which Dr. Lowman reports, in every one of which the milk-secretion was increased the day after the commencement of the jaborandi, while, when the drug was stopped, the milk at once commenced to fail in quantity, although perhaps not until four or five days after the discontinuing of the drug. On the other hand, Dr. Lowman refers to three other cases in which jaborandi was used with scarcely any effect at all.

*THERAPEUTICS OF UTERINE HEMORRHAGE.*

MENDES DE LEON reports in the *Arch. f. Gyn.* (xxvi. p. 147) his success with the use of hydrastis Canadensis in various forms of uterine hemorrhages. In fourteen cases the drug was given four times daily in 20-drop doses fourteen days before menstruation, and asserted its reputation (1) in menorrhagias, (2)

catarrhs of uterus, (3) chronic inflammation of the pelvic connective tissue, (4) retroflexion, (5) version of a fixed uterus, (6) climacteric hemorrhages.

As an explanation of the therapeutic effects of hydrastis Canadensis our author points to the general vascular contraction and subsequent diminished congestion of the genital organs. But in a few instances undesirable after-effects set in; twice grave nervous symptoms, such as delirium and unconsciousness, were noted.

*THE TREATMENT OF GONORRHOEA OF THE FEMALE.*

The inevitable result of not treated or half-treated gonorrhœa of the female is the extension of the disease to the uterus, thence to the tubes and ovaries and peritoneum. We can treat the disease effectively only while it remains in the vagina. Once let the virus reach the uterine membrane, whence it is but a step to the tubes, and the danger is imminent that local medication will be of little avail to prevent the following possibilities: sterility, salpingitis, oöphoritis, cellulitis, peritonitis. Nothing more should be requisite to prove the prime necessity of immediate and active treatment of gonorrhœa of the female, and attention has been recently directed to this subject by several papers which have been abstracted in recent numbers of the *GAZETTE*. One of the most important of these, by Dr. Currier, advocates the free application to the vagina of bismuth and glycerin. DR. E. H. GRANDIN (*New York Med. Journ.*, February 13, 1886), however, believes that far more active measures are needed and a far earlier application of treatment. Active treatment is indicated from the outset. The method which Dr. Grandin recommends is as follows: The patient occupying the dorsal position, choose the largest cylindrical speculum which can be inserted into the vagina. Wipe out the vagina thoroughly; then the cervical canal with a cotton-wrapped applicator. Take a fresh applicator, dip it in a solution of nitrate of silver (3ss to ʒi), and pass it to the internal os. Then pour into the speculum a teaspoonful or so of the same solution, and gently rotate the speculum out toward the vulva, thus keeping the vagina distended, and enabling the solution to come into contact with every portion of the mucous membrane. Depress the speculum, and allow the excess of solution to escape into a pus-basin. Reinsert the speculum, and place one or two vaseline tampons in the vagina. Remove the

speculum, and, separating the labia, paint the vestibule with a solution of the same strength. Next, if Skene's ducts are implicated,—and they usually are,—slit them, open with a narrow bistoury, and insert the fine point of a stick of lunar caustic to the bottom. Next, wipe out the urethra with a dry applicator, and then apply, as far as the neck of the bladder, a solution of the same agent (gr. x to ʒi). Finally, paint the vulva and surrounding parts with this latter solution, the object being to allay the itching and to destroy any virus which might linger there. The patient is to be told to remove the tampons at the end of twenty-four hours, and to wash out the vagina with a solution of chloride of ammonium (ʒii to Oi), this being preferred on account of its refrigerant action. This treatment is followed by no unpleasant reaction (on the contrary, the patients speak of immediate relief), and the sequelæ are none other than good. If thorough at the outset, it rarely will require repetition; but at the patient's next visit, in five or six days, we shall find the characters rather of a simple elytritis, and this we may treat according to special fancy. Dr. Grandin's is for the renewed use of the silver solution in one-third strength, to be followed at the after-visits by alterative applications (iodine) and by depletants (glycerin).

#### ACTION OF VARIOUS DRUGS ON ASCARIDES.

SCHRÖDER communicates to the *Arch. f. Exp. Pathologie* (xix. p. 290) the results of his observations of the action of numerous drugs on the ascaris family. For the purposes of experimentation he used the ascaris lumbricoides which occurs in the pig, and bears the closest resemblance to the parasites of the same class occurring in man. He found that of all drugs tried, sublimate and nicotine acted most deadly on the worm; very powerful also was soda-lye, which destroys the integument of the worm. A comparatively lesser effect was obtained from the following toxic substances in the following order: cyanide of potassium, arsenite of sodium, strychnine, conine, aconitine, and morphine, while alcohol, camphor, quinine, and all acids showed no deleterious effect at all on the insect. The observations made with santonine are rather interesting, though their results are somewhat surprising. Santonine, our author says, never kills the worm, but by some unknown reason merely forces the latter from its habitat, the small intestines, whence the worm is removed

by a purge. Hence the drug does not act by its destructive but by its expelling power. Therapeutically, the inference is to be drawn from this observation that a purgative is to be given simultaneously with or immediately after the ingestion of santonine.

#### A CASE OF AMPUTATION AT THE HIP-JOINT IN WHICH REINJECTION OF BLOOD WAS PERFORMED AND RAPID RECOVERY TOOK PLACE.

DR. A. G. MILLER reports in the *Edinburgh Med. Journ.*, February, 1886, a case of strumous disease of the left hip-joint, with a large abscess communicating with the joint. As opening and draining the abscess only gave temporary relief, amputation of the left leg at the hip-joint was decided upon. An elastic bandage having been applied from the toes to the middle of the thigh, and a powerful elastic tourniquet at the groin, a rapid circular cut was made down to the bone in the upper third of the thigh, and the femur sawn through. A gush of blood, estimated at about four ounces, took place, and was all caught in a vessel containing a solution of phosphate of sodium. The femoral artery and some smaller vessels were then tied, and the tourniquet removed. After this a few more vessels required ligaturing, and a few ounces of blood escaped, which, however, were collected and injected along with the previous quantity into the deep femoral vein. By an incision on the outer side of the thigh the head of the femur was then dissected out. The wound was thoroughly washed out with a corrosive sublimate lotion, dusted with iodoform, brought together with sutures, and the stump wrapped up in sublimated wool. After the operation the patient suffered from no shock whatever, nor had he any depression of temperature. He made an uninterrupted and good recovery, and three weeks after the operation was able to sit up in bed. The highest temperature recorded was 100.3°. There was slight hæmaturia for two days.

The patient being in a very weak and anæmic condition before the operation, and the hemorrhage during the operation having been greater than usual, owing to the great vascularity of the parts from the extensive disease, it is very unlikely that he would have survived the shock of the operation had the greater part of the blood not been reinjected.

Dr. Duncan, who watched the hemorrhage,

and measured the blood collected and reinjected, calculates that the patient had an ultimate gain of blood after the operation. He estimates it thus :

There was pressed back into the general circulation by the elastic bandage, say  $\frac{3}{4}$  v; reinjected of blood measured,  $\frac{3}{4}$  xi; lost in sponges and sawdust, say  $\frac{3}{4}$  iii; lost from destruction of corpuscles, say  $\frac{3}{4}$  i; net gain of blood, say  $\frac{3}{4}$  i; but to this must be added lymph from leg, say  $\frac{3}{4}$  v; solution,  $\frac{3}{4}$  iv; and also a diminished demand on the general circulation on account of the leg having been removed.

#### ADONIDINE IN CARDIAC DISEASES.

It must always be difficult to find a remedy which can replace digitalis; and yet in view of the inconvenience which the constant use of digitalis entails, a drug which would combine the advantages of digitalis and would be free from its disadvantages is greatly to be desired. DR. E. DURAND (*Journ. de Méd.*, December, 1885) has made a number of comparative studies of various cardiac drugs in the hospital service of Dr. Desplats at Lille. The drugs which he has studied are digitalis, caffeine, convallarine, and adonidine. Digitalis, as is well known, is often badly tolerated, does not act immediately, and cannot be given for any length of time without danger of cumulative effects, and is not admissible in cases in which the kidneys are diseased. Caffeine, whose advantages are not yet sufficiently known to practitioners, frequently produces insomnia and a state of nervous excitement which necessitates its withdrawal. Convallarine appears to be extremely irregular in its reaction, judging by the contradictory opinions which have been published upon it. Adonidine, the active principle of *adonis vernalis*, appears to be free from bad effects, and all physicians who have heretofore employed it attribute to it properties analogous to digitalis. It increases the energy of the cardiac contractions, regulates the pulse, and diminishes its frequency. It is rapidly eliminated, and never occasions secondary action from cumulation in the organism. Finally, it increases in a marked degree the quantity of urine, and hence serves to remove dropsies and œdema. All these facts have been observed by M. Durand, with the exception that the influence on diuresis was only marked in one case, in which it doubled the quantity of urine passed in twenty-four hours. He concludes that the indications for its employment

are the same as for digitalis. The daily dose employed was  $\frac{1}{10}$  of a grain in pill form. In some cases the dose was increased to  $\frac{1}{5}$  without producing any phenomena of intolerance.

#### SALICYLATE OF LITHIUM IN RHEUMATISM.

VULPIAN read before the Paris Academy of Medicine recently a paper in which he claimed certain advantages of salicylate of lithium over the salicylate of sodium. We abstract without comment some of the principal points of his paper, as found in the *Deutsche Medicinal Zeitung* of January 14, 1886 :

In spite of the acknowledged specific influence which salicylate of sodium exercises over the rheumatic process in general, every practitioner has met cases which proved absolutely refractory to this medication. In some forms of rheumatism, such as the gonorrhœal, in the subcutaneous articular and chronic articular, the sodium salt has little if any power. In these forms the salicylate of lithium has, in the hands of Vulpian, given fair results, and proven by all means superior to the salicylate of sodium. Wherever the fibrous tissues are first and prominently affected, the lithium salt appears to act better. In some chronic cases, in which the sodium salt had been exhibited for a long time without the slightest effect, salicylate of lithium gave relief in ten to fourteen days, removing pain, swelling, and functional disturbance. Improvement was also obtained in some very advanced cases marked by semi-ankylosis and deformities. The salt is easily soluble in water, has an agreeable taste, and may be given in doses of 7 grains. The daily ingestion ought not to exceed 1 drachm. The drug is, however, by no means free from unpleasant after-effects, though patients who were treated by both the sodium and the lithium salt gave the latter the preference.

#### STRETCHING OF THE SCIATIC NERVE FOR SCIATICA.

DR. J. C. MEHAN reports in the *Med. and Surg. Reporter*, January 9, 1886, a case of neuralgia of the sciatic nerve in which almost every known form of treatment had been employed unsuccessfully. Morphine in injections of  $\frac{1}{4}$  to  $\frac{3}{4}$  of a grain had been given three times daily; quinine in large doses, injections of chloroform and ether and iron, arsenic and atropine, gelsemium, iodide of potassium, aconite, and various other drugs

had failed; massage and various liniments and blisters had been used; and under the influence of chloroform the course of the nerve had been burnt with an iron heated to a white heat. All had failed in producing any relief with the exception of morphine, and this only produced ease while its narcotic effects lasted. The operation of nerve-stretching was then done, the nerve being stretched with sufficient force to lift the lower half of the body from the table by means of grasping the nerve and lifting. The nerve was then replaced in its proper position, and the wound sewed up and carbolic acid applied. For a few days after the operation the patient suffered considerable pain, but this grew less after a short time, and he became comparatively comfortable. The wound was four weeks in healing. During this time the most pain experienced was in the knee down to the foot, but was readily bearable. When he left the hospital he had still slight pain in the nerves, but went to work in a few days. For the following six weeks he still had a little pain, which gradually left, and which since has not returned.

#### THE ACTIVE PRINCIPLES OF THE VARIOUS VARIETIES OF ASCLEPIADEÆ.

The family of the asclepiadæ contains numberless species, which are all poisonous, and whose specific action appears to be the production of violent vomiting and diarrhœa. The emetic properties appear to be dependent on the presence of emetin, and their preparations may be substituted for ipecacuanha. C. GRAM (*Deutsche Med. Zeitung*, January 25, 1886) has experimented with the glucoside asclepiadin, discovered by Harnack, and has found that when boiled with acids, or when evaporated out of neutral solutions over the water bath, or even when allowed to stand in the open air, it decomposes into sugar, and a substance entirely insoluble in water, brownish yellow in color, and of a resinous character, which he terms asclepiadin. This substance in frogs, after producing vomiting, soon causes total paralysis and death. Asclepiadin in frogs causes motions of vomiting and paralysis, and at first increases and then decreases reflex irritability. In warm-blooded animals asclepiadin produces arrest of respiration, and, as a consequence, irregular action of the heart and convulsions from dyspnoea. If artificial respiration is carried on, the heart becomes more regular, until death is suddenly produced through heart-paralysis.

These symptoms show a great similitude to those of emetin.

#### THE TREATMENT OF ALOPECIA AREATA.

DR. G. T. JACKSON publishes an interesting article in the *New York Medical Journ.* of February 20, 1886, which contains many points of value as to the treatment of this form of baldness. In the first place he points out that the hygiene of the patient should be looked after, and it will be often found that tonics are required, and of these cod-liver oil, iron, and phosphorus are the most useful.

The local treatment consists in stimulation of the scalp. In the beginning of treatment it is well to remove by epilation all the loose hairs about the margins of the patches. The best method of effecting this is by pulling the hair between the thumb and an ordinary spatula or stout card held in the hand.

For stimulants, carbolic acid, tincture of cantharides, cantharidal collodion, tincture of nux vomica, veratrine, capsicum, phosphorus, or aconite, sulphate of quinine, strychnine, liquor ammoniæ fortior, sulphur, bichloride, yellow sulphate, and oleate of mercury, croton oil, and castor oil, each and all have their advocates, and are used either separately or two or more of them combined. As the diseased scalp will bear, as a rule, a good deal more stimulation than the healthy scalp will, we must regulate the strength of our chosen stimulant solely by the amount of reaction it causes. Thus, liquor ammoniæ fortior, in full strength, may be freely applied to the scalp, and its use persisted in for weeks without apparent over-irritation of the scalp.

Good results have been reported from the use of electricity, the galvanic current being used with one pole at the nape of the neck, and the other brushed over the affected parts. Hypodermic injections of  $\frac{1}{4}$  to  $\frac{1}{10}$  grain of the hydrochlorate of pilocarpine every few days are well spoken of by some observers.

The treatment by blistering has in some cases produced rapid results. For this purpose either croton oil or cantharides may be used. Thus, Horand advises painting the bald spots with croton oil, covering with cotton, and wearing a hood over all. If ulceration is caused, the part is to be dressed with olive oil. When healed, the application of the croton oil is to be repeated. This method of treatment is to be continued till the hair grows. Vidal recommends the following: If the subject is a child, the whole head is to be shaved. If the patient is older, the scalp is

to be shaved for half an inch around the bald spot. Now apply a blister, which should never be larger than a twenty-five-cent piece, to each bald area, putting it on in the morning and taking it off when the epidermis begins to rise. If a large bleb forms, it should be opened. Powder the blisters with starch and cover with linen. If there are numerous bald spots, apply the blisters to them successively. If the hair does not grow after thorough blistering, repeat the operation as soon as the effects of the first application have disappeared. If blisters are not well borne, use sinapisms. When the hair begins to grow, shave, and rub in, every morning and evening, a lotion of

R. Liq. ammon., 4 parts;  
Alcohol, 16 parts;  
Decoct. foliæ juglandis, 120 parts. M.

For alopecia areata of the face he uses blisters in some cases. Generally he has the part shaved every day and uses frictions of tincture of cantharides, either pure or with one-fifth to one-sixth tincture of rosemary.

In a few cases Dr. Jackson has produced benefit by using a pomade of jaborandi made by boiling down the fluid extract to one-half its volume, and adding this to lard in the proportion of one of the jaborandi to four of the lard. This is to be thoroughly rubbed in twice a day. In the first case of the recurrent type, the hair in two relapses returned under this treatment in the course of ten weeks. But it had no effect in preventing the formation of new patches. In the second case, occurring in a child with chorea, after the use of various other remedies for three months, the spots continually growing larger, the jaborandi was used, and in ten weeks the disease had ceased spreading, and the hair was growing on every patch. In a third case, affecting the moustache of a medical student, its use was followed in seven weeks by the appearance of new hairs in the patch, shaving being practised at the same time. In all these three cases the return of the hair took place some six or seven months after the beginning of the disease.

In his last cases of alopecia areata, Dr. Jackson has used a solution of corrosive sublimate, not on account of its parasiticide qualities, but solely for its stimulating effect. The strength of the solution used was three parts of the bichloride of mercury in one thousand parts of water, or say one grain and a half to the ounce. This was applied once or twice a day, and has given satisfactory results.

#### A SPECIFIC FOR THE TREATMENT OF HERNIA.

DR. DOROTEO DE ARMAS publishes an article in the *Union Médicale de Caracas* (*Bull. Gén. de Thér.*, No. 28, 1885), in which he claims that the peasants of Venezuela produce a radical cure of hernia by means of a parasitic plant which grows on the *Bowdichia virgiloides*. The boughs of this parasitic plant are stripped of their leaves, and then scraped with a sharp instrument so as to remove all the inactive portions of the bark; the remainder is then chopped up and mixed with water to form a semi-solid paste. After the lapse of some time an extractive matter separates, which is at first greenish, but then becomes almost black. It is elastic, semi-solid, and capable of being drawn out in long filaments, which stick to the hands, and gradually harden when exposed to the air. The mode of employment is to spread a thick layer of this substance on a piece of linen, and, after having well shaved the skin, to apply it over the hernial tumor, where it is maintained for forty days to two months. Dr. Armas refers to two cases of cure with which he is himself personally acquainted. He believes that this mode of action is on the one side attributable to its contraction, and so renders it analogous in its application to a truss; and he believes, on the other hand, that it exerts special influence over the hernial rings.

#### THE TREATMENT OF RINGWORM OF THE SCALP.

At the last meeting of the Medical Society of the State of New York, Dr. FREDERICK C. CURTIS gave a summary of the results which followed his treatment of a number of cases of this affection. Oleate of copper was first used, but its employment was not followed by any benefit. Chrysophanic acid was next tried in a variety of ways. First, a ten per cent. solution in liquor gutta-percha was tried, as has been recommended by Dr. W. T. Alexander. The heads were shaved once a week, and, after they had been thoroughly scrubbed, this mixture was painted over the affected spots, in some cases nearly the entire scalp. It makes an impervious, dry covering or mask, liable to crack, however, and all such cracks and all loosened places received additional coats daily. A number of patients were materially benefited by this, but very few permanently, though some were cured.

Another method of applying chrysophanic acid was used by Dr. Henry Hun, of the

medical staff. After the scalp was shaved, an ointment, of the strength of a drachm and a half to the ounce, was rubbed into the spots, which were then covered with successive layers of adhesive strap. This, as might be anticipated, produced a good deal of irritation and œdema, but in no case suppuration. It was repeated two or three times at considerable intervals. Some cases were cured by it alone. It is to be recommended only for limited areas and with caution in an ointment of this strength, and it is not desirable to attempt entire destruction of the parasite with it, but to complete the cure by simple means.

Chrysophanic acid was also used, as proposed by Dr. Alexander Smith, in solution in chloroform, seven grains to the ounce. In these cases depilation was used daily, the solution being applied after it. The chloroform penetrates the hair-follicles more effectively than other agents. It produces no irritation of the scalp, and is of value. It was used only after the other appliances had been employed. It has no advantage, however, over an ointment of carbolic acid, or one of the tars with a mercurial ointment. By means of these two appliances, with depilation, all the cases not previously cured were brought to an end about the last of July, some four months after treatment of the epidemic was begun.

Dr. Curtis's conclusion is that chrysophanic acid is a reliable parasiticide, and that, combined with an impermeable covering, it will cure a fair proportion of cases without the labor of depilation, materially relieving those not cured; that it does not act by setting up a suppurative inflammation, being as to this well borne by the scalp. The impermeable covering is of very considerable value, not only as neutralizing the conditions favoring reinfection, but also by evidently hampering the growth of the fungus, if not to a degree destroying it. In none of the cases has permanent baldness resulted. It has been said that tinea capitis will finally disappear without treatment, but the natural history of the disease must be a long one; under the most fortunate treatment it will last from three to six months usually.

In regard to the exact point of time when the disease may be pronounced cured, it is often difficult, though always important, to determine. Duckworth's chloroform test, by means of which, as asserted, the hairs containing fungus are turned a distinctive white color, is not of value, since it would only be appreciable when the amount of fungus was considerable, and also since the hair is

far from normal even when the fungus is completely destroyed. The microscope is also of negative value, for it often failed to discover fungus in cases when the disease was not cured. As to the growth of healthy hair, in old cases this will not appear till long after the disease is cured. The best test is the appearance of the scalp itself. If, after one or two weeks' suspension of all treatment and washing, the cuticle is found free from the ashen-gray scales and the goose-flesh appearance, and the still bald patch is smooth, of a normal color, and free from the stumps of broken hairs, it is then safe to discharge the patient from quarantine. The entire surface of the close-cropped scalp must be searched for possible foci. Often the question will be complicated by the scaliness of slight eczema or pityriasis. But generally we can trust to this test.

#### URETHAN AS A HYPNOTIC.

DR. STICKER draws the following conclusions from his investigations as to the action of urethan (*Deutsche Med. Zeitung*, January 25, 1886). Urethan is an excellent cerebral hypnotic, and possesses advantages over the usual hypnotics in that it is well borne, produces absolutely no unfavorable symptoms, and causes sleep which appears to be perfectly similar to the physiological state. Urethan appears to be indicated in cases in which the other hypnotics, either on account of their unfavorable action on the heart or respiration, on account of their taste, or for some idiosyncrasy of the patient, have to be reduced or stopped. The minimum dose is 15 grains, but in persons from fifteen years of age and upwards this may be increased to 60 grains without danger. The best mode of administration is in capsules or in watery solutions, with some syrup to correct the taste.

#### THE TREATMENT OF INCONTINENCE OF URINE IN CHILDREN.

There is scarcely any disease occurring among children more annoying and troublesome than incontinence of urine. It is particularly vexatious to parents, and is often regarded by them as an incurable infirmity. After their patience has been long tried, they abandon one remedy after another and look forward to puberty, when, they are told, the disease may depart, never to recur. According to Dr. DAY (*Brit. Med. Journ.*, February 13, 1886), failure in treatment is frequently

owing to an erroneous diagnosis of the affection; to the inefficiency with which the treatment is carried out; to its being discontinued too soon. Among the causes of enuresis, the following may be enumerated. If the urine be excessively acid or loaded with urates, the bladder becomes overstimulated and readily discharges its contents; if the bowels be habitually costive, or there be worms in the intestines, vesical irritation may ensue; or, if the child be guilty of masturbation, there will be no chance of cure till the habit is corrected. Weakness of the muscular coat of the bladder from general debility or anæmia is a very common cause; the bladder, not being able to tolerate any quantity of urine, readily excites the motor apparatus. Dr. Day has known a troublesome case follow typhoid fever in a boy ten years of age. If the disease be owing to a long prepuce, causing phimosis, it should be removed. Sometimes no cause can be ascertained. Children two or three years of age frequently wet the bed, either from laziness or from lack of control over the bladder. It is important to remember that, even though the secretions are in perfect order, the incontinence may continue, and thus a habit may be formed which the poorer classes and stern people occasionally endeavor to correct by punishment. In some idle and dirty children such a course may be of benefit; but in others who are nervous and timid there is the possibility of increasing the evil we desire to remove.

Enuresis is sometimes seen in connection with chronic albuminuria, and is occasionally so persistent as to require special treatment. It seems impossible to lay down a plan of treatment for general adoption; the peculiarities of constitution and habits of life must be taken into consideration, and hap-hazard treatment guarded against. Some cases are cured or relieved by the combined influence of electricity, iron, and belladonna. The successful issue is in a great measure attributable to the constant care which the mother takes in feeding the child and rigorously attending to the physician's instructions. Those cases that date from birth or have lasted upwards of a year are invariably intractable and often incurable, especially if the child be of nervous parentage, or was delicate when born, or passes large quantities of urine. With respect to the utility of faradism there can be no question; it requires to be used regularly, and to be continued for a considerable time, but it sometimes fails altogether. When the nervous system is weak, and there is gen-

eral debility, the sphincter loses its power, and urine escapes by night and day without the child's knowledge. It is in such cases as these that iron and nux vomica are of service.

If there be excess of muscular action, and the child have frequent inclination without power of control, belladonna is an admirable remedy. It occupies a prominent place as a therapeutic agent, and sometimes, when combined with iron, even in small doses, it seems to do good; but it should not be given up in obstinate cases, till either soreness of the throat is produced or dilatation of the pupils takes place. In Dr. Day's hands it has often failed when administered in any form or dose. It certainly tends to lessen irritability of the bladder, and should always have a fair trial.

Cold sponging in the morning is very serviceable in cases of enuresis that appear to have their origin in general debility. It braces up the nervous system and is a powerful tonic. The slight sensation of chilliness soon passes away without leaving any depression if vigorous friction with a towel be employed for a few minutes. In a case under Dr. Day's care about three years ago, the cure was attributed to this simple measure when one remedy after another had failed. The vital functions are brought into a healthier state, the skin acts better, and the appetite and digestion improve. However delicate a child may be, free sponging in tepid water, followed by a good rubbing, is of great value.

#### *THE TREATMENT OF EPILEPSY WITH BORAX.*

Although there are many remedies suggested for the treatment of epilepsy, the number from which any permanent benefit is derived is exceedingly small,—so small that probably few physicians think of prescribing anything but some of the preparations of the bromides, unless they have already been tried and failed. It is true that some benefit is the usual result of the use of the bromides, often marked improvement, sometimes cures. But their use is attended with disadvantages, if given in sufficient quantity to control the attacks, in the vast majority of cases; and with certain individuals these common uncomfortable symptoms are so excessive as to make the bromides, when taken for a long time, a greater source of annoyance than the convulsions themselves. There are some cases, also, in which no benefit is derived from the bromides in any possible combination of their salts, or whether with ergot, bella-

donna, ammonia, and other drugs, or alone; it now and then happens that they make the disease worse, and exceptionally they give rise to maniacal symptoms. It is not seldom that they cannot be used.

Their common effect is to impair appetite, interfere with digestion, and produce a certain amount of mental and physical sluggishness, which may amount to a settled gloom and indisposition to effort, and which is generally attended with some loss of flesh, even if not great, unless some tonics are given, or special efforts are made to keep up the general health; and, if given to the extent of controlling the convulsions, the bromidism produced is often so disagreeable to the patient that other remedies must be sought for. The list of drugs which have been tried in such cases is long.

In the *Boston Med. and Surg. Journ.*, February 18, 1886, Dr. CHARLES F. FOLSOM calls attention to the use of borax, and reports cases in which the use of borax, commencing with 10 grains three times a day, and then increasing up to 15 grains, finally to 20 grains three times a day, served to greatly reduce the number of convulsions, even although nearly all the other methods of treatment had proved unavailing. In other ways the improvement was also great: the attacks of petit mal, which formerly were almost incessant, occurring sometimes twenty in a single hour, are now very seldom the source of annoyance, while the general health is almost perfect. The only annoyance noticed was a dry, scaly eruption, giving rise to a good deal of itching, but which disappeared after several weeks' use of arsenic internally and oxide of zinc ointment with vaseline given externally. Aromatic tinctures given with the borax prevented the nausea which immediately followed its use when mixed with water alone. Borax cannot be claimed ever to cure absolutely cases of epilepsy in which the bromides have failed, but it nearly always will produce improvement in the general health and will lessen the severity and frequency of the convulsions. Dr. Folsom especially recommends the alternate use of borax and bromides, particularly in cases which have been for a long time under the influence of the bromides, and which are therefore in the wretched condition nearly always caused by prolonged use of these drugs. The first few doses of borax often produce diarrhoea, which soon ceases. Eruption on the skin is readily controlled, and the tendency to nausea, flatulency, and indigestion is easily met by chloroform, tinc-

ture of cardamom, compound spirits of lavender, etc., given with the borax.

#### THE PREPARATION OF TERPINE.

We have already published reports as to the action of terpine as an expectorant. The following formula is given for its preparation (*Pharm. Post*, January 23, 1886): Rectified oil of turpentine 4 quarts, alcohol (80°) 3 quarts, nitric acid 1 quart. This mixture is placed in a flat porcelain vessel, and allowed to stand for several days. The crystals, which by this time have formed, are dried by pressure between layers of filter-paper, and are again crystallized out of 95° alcohol, by which means the nitric acid, which is still clinging to the terpine, is separated. About twelve per cent. of the turpentine employed is obtained as terpine.

#### THE NEUROTIC TREATMENT OF CATARRH.

At the meeting of the Harveian Society of London held February 4, Dr. LEES read a paper with the above title (*British Medical Journal*, February 13, 1886).

Dr. Lees limited the word catarrh in his paper to its original meaning of coryza, and pointed out the many troublesome and even disastrous results which might ensue from a neglected cold, and the unsatisfactory nature of a merely diaphoretic treatment. He defined catarrh as a neurosis of the vaso-motor nerves, excited in a reflex manner by impressions of cold on the cutaneous nerves. He pointed out that congestion and hyperæsthesia of the nasal mucous membrane was a result of this vaso-motor paralysis, and that, conversely, there were reasons for thinking that a morbid irritability of this part might itself excite catarrh, an illustration of this latter process being found in hay-asthma. The question of the origin of catarrh from germs was considered, and the arguments in its favor stated, including the undoubted contagiousness of some colds and the analogy of such diseases as influenza, measles, and whooping-cough. But to ascribe all catarrhs to germs was premature and probably incorrect. Catarrh being a neurosis, relief must be sought by the aid of neurotic remedies. The indications for treatment were three: to quiet the excitement of the central nervous system, to soothe the local congestion and hyperæsthesia of the nasal mucous membrane, and to arrest the flux if it had already commenced.

The first indication was to some extent met by opium, but much more satisfactorily by a full dose of bromide of potassium, and this drug had the further advantage of great safety. The second object was easily accomplished by painting the interior of the nose with solution of hydrochlorate of cocaine. The arrest of the flux was to be accomplished by the administration of belladonna, a drug whose first obvious physiological action was to cause dryness of the mouth and throat. The author had found the following method promptly and permanently successful in cutting short a cold. From 40 to 60 grains of bromide of potassium were given at once, the dose being repeated in six hours, and again, if necessary, six hours later; and 20 drops, equal to 15 minims, of tincture of belladonna were also given every hour, or every two hours, until the throat felt a little dry. Painting the nasal mucous membrane with a four per cent. cocaine solution gave great relief, and might even by itself suffice to arrest a cold. Dr. Lees concluded with the account of a case in which 10 grains of bromide of potassium, with 8 minims of tincture of belladonna, had in less than forty-eight hours completely arrested a very pronounced nasal and pulmonary catarrh, with much dyspnoea, in a highly rickety child aged 4, whose chest was much deformed; and he suggested that, from the known danger of this condition in such children, it was not improbable that in this instance a life had been saved by the adoption of a neurotic treatment of catarrh.

#### AMPUTATION OF THE THIGH UNDER THE USE OF COCAINE AS AN AN- ÆSTHETIC.

DR. T. R. VARICK reports in the *New York Medical Journ.*, February 20, 1886, the first attempt at a major operation in which Dr. Corning's method, already referred to in the GAZETTE, was employed to produce anæsthesia with cocaine. The case was one of compound fracture of the right leg, in which, after a period of five weeks, all attempts at saving the limb having proved abortive, amputation was decided upon. An attempt to administer ether was attended with such alarming symptoms that it was abandoned.

The operation by antero-posterior flaps was the one chosen, cutting from without inward for the interior, then transfixing the limb, and making the posterior flap by cutting from within outward.

1. The first incision through the integument—no pain.
2. The second incision through the deeper tissues to the bone—no pain.
3. Transfixion of the limb—no pain.
4. No pain until near the completion of the wound, which was occasioned by carrying the knife beyond the line marked on the integument.
5. On carrying the knife around the bone to divide a few remaining attachments, there were some manifestations of pain.
6. The use of the saw occasioned loud complaints, although the subsequent removal of a spiculum with the bone-forceps was not noticed.
7. There appearing some redundancy of flap, the scissors were used for the purpose of trimming. This procedure was absolutely painless.
8. The insertion of sutures was unnoticed, except at the angles of the wound.

After the ligation of the vessels, which was painless, hot water, slightly below the boiling-point, was applied to the abraded surface, with no expression of pain.

ACNE: ITS ETIOLOGY, PATHOLOGY, AND TREATMENT.  
By L. Duncan Bulkley, M.D.

New York and London: G. P. Putnam's Sons,  
1885. Pp. 280.

The author well says, "The science and practice of medicine is built upon the study of single diseases and groups of diseases, and monographs may be called the foundation-stones upon which the structure is reared, or the quarries from which the material is drawn." And the monograph here presented is another of Dr. Bulkley's contributions, fully as valuable as his monograph on eczema. The title of the book, however, will be misleading, as the inference follows that it treats only of the disease commonly known as "acne." On the contrary, several other important diseases, among which may be mentioned that known as seborrhœa—in short, the functional and inflammatory diseases of the sebaceous glands—are here treated, and comprised under the one general term. That this is theoretically justified we may possibly admit, but we must nevertheless look upon it as confusing, as it is not in accord with the prevalent teachings of the day. The substance of the work, however, is valuable in every respect, and it will

prove an acceptable addition to the library of general practitioners, and also to specialists.

All the diseases considered—namely, those usually described as *seborrhœa*, *comedo*, *milium*, *sebaceous cyst*, *acne vulgaris*, and *acne rosacea*—are handled in the author's clear style, and the treatment of the different affections is full and intelligible. Dr. Bulkley not only mentions what remedies to use, but how and when to use them.

The author states, in considering the subject of etiology, "but the more the subject is studied in all its bearings, the more does it seem probable that in the majority of instances the direct cause of faulty secretion from, and congestive and inflammatory action in and about, the sebaceous glands is found in a nerve-influence transmitted or reflected from other organs or portions of the body." A chapter on diet and hygiene in relation to the diseases here considered is added.

The same plan is followed in regard to the formulæ given as in the author's work on *eczema*: the formulæ are added in a supplementary chapter, and omitted from the body of the work, reference being made to them by numbers. This plan, it is true, saves a slight amount of space, as many would necessarily be repeated, but it detracts from the smooth and easy reading of the book.

Apparently the bibliography which is added is complete, and, although of little interest to the general reader, is valuable to the cutaneous specialist.

In conclusion, we congratulate the author on the production of a second monograph that will add still more to his present well-earned distinction.

ECTANEUS MEMORANDA. By Henry G. Piffard, M.D.  
Third Edition.

New York: William Wood & Company. 1885.  
Pp. 267.

As long as there is demand for such books as the "pocket manuals" there will be a supply; and that there is a demand is proved by the appearance of a third edition of the little book before us. As is to be expected from all writings emanating from Dr. Piffard, this volume contains much practical information, and it is given in the author's usual positive style. In the present edition additional text and some new illustrations have been added.

OFFICIAL FORMULÆ OF AMERICAN HOSPITALS. Collected and Arranged by C. F. Taylor, M.D.

Philadelphia: Published by *The Medical World*.

This little volume meets a recognized want. On the part of druggists especially, into whose

precincts occasionally stray patients from hospital out-wards and dispensaries with prescriptions calling vaguely for some Mixture No. 2, *Mixtura Anti-Rheumatica*, or some equally perplexing combination. To such the book will prove a godsend; also to the young practitioner who has a sharp appetite for formulæ, and believes that the physician's province is to cure. Incidentally, it will be serviceable to the numerous class of aspirants who are engaged in starting new dispensaries, so that the poor can receive gratuitous advice, and make the acquaintance of a few skilful gentlemen whose time is a drag on their hands.

The number of hospitals represented is not very large, and some institutions of note contribute very few formulæ, but among them all one meets occasionally a new combination, and that is something at the present day, when there is so little new under the sun.

RATIONALISM IN MEDICAL TREATMENT, OR THE RESTORATION OF CHEMISM, THE SYSTEM OF THE FUTURE.  
By Wm. Thornton.

Boston: Published by the author, 1885.

"To those who think and reason" this work is dedicated, and it may, perhaps, appeal to those who cannot think and whose reason is overthrown. Each leaf is printed on but one side of its heavy tinted paper, lest perchance its precious truths should strike through and damage some equally precious truths on the reverse page. The author speaks of an atmosphere of invective and air that has to clear away before his great discovery can burst upon us; but, after reading the book through with expectation, we find nothing; in fact, he has reserved the revelation of his great discovery for a subsequent volume. The fact that "no book can aid in the development of rational medicine, renders it necessary that he," being the authority, should "begin to open this vista through which others may see." A lovely metaphor, but erroneous, the author imagining a "vista" to be something like a telescope or a peep-hole. Throughout the book we find the word "death" quoted continually, which seemed unaccountable till near the end in the chapter on the lucid topic of "Life, Material, and Death," we learn that there is *no* such thing as "death," and his perpetual quotations are but his quiet protest against an idea for which he will not be held responsible. His idea, the idea that we gather from the book, is that disease arises from a withdrawal of some one or more of the normal chemical elements of the living body, that its cure can only be effected by refurnish-

ing it again with these diminished or absent elements. The style is intricate, the expression clumsy. Yet at times he rises to something like eloquence, almost Socratic, as where he asks, very pertinently, "What are we to understand by this?" and in a line more, as though Bunsby himself were risen from the second volume of "Dombey & Son," "*Be* that as it may, what answer?" At times sententious, as "The body is not composed of drugs but chemicals," "A man cannot live on crude chemicals," "The body is crude chemical matter clothed in flesh." Still, he cannot hide the fact that he is grossly ignorant of medical science in all its branches, and that he has as yet no grand truth of his own discovery to reveal. The reader will be apt to add mentally that the chances of his ever discovering or revealing anything valuable are very small judged by "Rationalism in Medicine, or the Restoration of Chemism."

EPITOME OF DISEASES OF THE SKIN. By Louis A. Duhring, M.D.

Philadelphia: J. B. Lippincott Company, 1886. Pp. 130.

This little book is an abstract of lectures delivered before the graduating class of the University of Pennsylvania. The various diseases are described intelligently but briefly, practical points of treatment given, and some of the more important formulæ incorporated. Although the volume is, as the author states, to be regarded merely "as an epitome of the subject," yet the general practitioner and student can find in its pages much that is valuable and suggestive.

VENEREAL MEMORANDA: A MANUAL FOR THE STUDENT AND PRACTITIONER. By P. A. Morrow, A.M., M.D., etc.

New York: Wm. Wood & Co., 1885.

The author's aim is to "boil down" the existing literature on venereal diseases, to give us a real pocket manual, and to fix the main points in the mind by brevity and terseness of expression. We think he has succeeded admirably. His formulæ are time-honored as well as modern, his recommendations are sound, and the advice to the practitioner reliable.

BACTERIOLOGICAL DIAGNOSTICS. By James Eisenberg. Hamburg and Leipzig: Leopold Voss, 1886.

There are many physicians both in America and in Europe who do not believe in the microbic theory of disease. Some physicians go even as far as to regard the entire subject and its promulgators fallacious, while the latter

view the parasitic etiology of all constitutional diseases as *un fait accompli*.

The truth, as always, lies probably in the middle. Some, but as yet undefined, relation appears to exist between disease and microbe, though it remains to be proven that the latter is always or the only etiological factor.

Meanwhile, the bacteriological science is making rapid and unexpected strides forward, and imposes upon the intelligent physicians of the world the necessity of making themselves acquainted, *volens volens*, with this new and certainly interesting subject. The pilgrims to Koch's laboratory—the Mecca of bacteriology—are numerous, and nowhere can a scientific building boast of a more international character than the gray old "Reichsgesundheitsamt." Occasionally the foreign pupils take a hand, even at original researches and publication, as is the case with Dr. James Eisenberg, who has just published a pamphlet called "Bacteriological Diagnostics." The little work is a ready hand-book and medium of reference for the bacteriological science up to its present development. It is divided into three parts:

I. Non-pathogenetic bacteria.

α. Rendering gelatin fluid.

β. Not rendering gelatin fluid.

II. Pathogenetic bacteria.

α. Cultivated outside of the animal economy.

β. Not yet cultivated outside of the animal economy.

III. Micrococci.

Altogether, we find seventy-six different species of microbes discussed both morphologically and in their relations to disease. To gain an insight into the nature of these reference-tables, for such they actually are, we find the microbes discussed under the following columns: Habitat, name, discoverer, literature, motility, growth (plates, puncture culture, potatoes, blood serum), temperature, rapidity of growth, formation of spores, need of air, gas formation, relation to gelatin, coloration, pathogenetic relations.

The work, which is dedicated to Prof. Koch, and which, as we understand, is being translated into English by Prudden, of New York, deserves a favorable recommendation.

HOSPITAL SISTERS AND THEIR DUTIES. By Eva C. E. Lückes, Matron to the London Hospital.

Philadelphia: P. Blakiston, Son & Co., 1886.

To those aspiring to become hospital sisters this book will be invaluable. Its advice from the writer's stand-point is excellent. Nothing

is too trivial or minute for mention. The system of nursing is everything, and pervades everything. The hospital is but the field appointed for its perfect evolution. Sisters and probationers, nurses and night sisters, staff nurses and ward maids,—these are the shining bodies that make up the system, and if on the outskirts there revolve more distant ponderous and dismal bodies, far from light, these perchance are doctors, and the nearer orbs regard them not. This is the story of the book. Nurses are a necessity, good nurses are treasures beyond price; but surely human beings do not fall sick solely that the system of nursing should be exhibited; wards are not built and filled with sick and injured that nurses may have a field. A very short and hurried perusal of these pages will convince all but the most wrong-headed of the very undesirable state of things which it holds up for our admiration. One asks in astonishment, Where in this scheme does the doctor come in? True, he is hinted at vaguely, as on p. 125, "The responsibility of deciding whether the condition of the patient renders it desirable for his name to be added to the 'dangerous list' does not finally rest with the sisters, but this is nevertheless a matter," etc. True, we occasionally find something better, as "to help the doctor, not to add to his difficulties, is the object a hospital sister has to keep in view;" but more often he floats in the vague distance, while the foreground is filled with the small bustle of ward, ward kitchen, and scullery. So that, while there is much of value in the book, much that tends to help the nurse, we would be sorry to see the whole system as here exhibited firmly rooted and flourishing on our own soil.

POST-MORTEM EXAMINATIONS WITH ESPECIAL REFERENCE TO MEDICO-LEGAL PRACTICE. By Professor Rudolph Virchow. Translated by J. P. Smith, M.D. With additional notes and new plates. From the Fourth German Edition.

Philadelphia: P. Blakiston, Son & Co., 1885.

This exceedingly useful book may well drive all other similar works from the field. Nothing more practical, minute, systematic, and intelligible has ever appeared in print upon the subject. The smallest matters receive due attention, and care and method are inculcated on every page. The book is well illustrated, convenient in size, and printed in clear, readable type. To its production have been brought all the traditions and observations of the most careful, minute, and painstaking school of medicine in the world, and we cordially recommend it to all those who desire to

become truly proficient in the important matter of post-mortem research.

TRANSACTIONS OF THE STATE MEDICAL SOCIETY OF WISCONSIN, 1885.

TRANSACTIONS OF THE MEDICO-CHIRURGICAL FACULTY OF THE STATE OF MARYLAND, 1885.

The address of the president of the Wisconsin State Medical Society, subject, "Fraternally Yours," forms the most interesting portion of the Transactions. Throughout runs a vein of barely concealed sarcasm. In relation to professional good feeling, "Fraternally Yours" would meet the author's views of the real state of things most exactly. And in support of this term we find long quotations from the code of the American Institute of Homœopathy, showing what liberal fellows they are; how they have our books on their shelves, our code or a better one in their hearts; how they are now free from any taint of dogma, and are ready and willing to consult with us whenever and wherever we please. We do not wonder at finding in the report of transacted business that the Society reaffirms its steadfast adherence to the code of ethics, and that the president desired to "modify certain portions of his address." As for the medical work of the Society, the Transactions of State societies are seldom used in our medical schools as text-books.

The Transactions of the Maryland Society contain much interesting matter. The president's address on "The Origin and Diffusion of Cholera" is a careful résumé of the subject. The annual address, by Dr. H. Newell Martin, on "The Study of the Physiological Action of Drugs," is a bright, thoughtful, and valuable paper. Under the section of Obstetrics and Gynæcology we have an extended notice of a modification of the Tarnier forceps, well illustrated. There are papers on "Antipyrine," on the "Tonic Effects of Travel," on "Cremation," "Cocaine," "Insanity," "Rectal Medication," and many other interesting topics, forming a volume very creditable to the efforts of the Society, showing, as it does, patient research and faithful work.

### THE TREATMENT OF DIPHTHERIA.

To the Editors of the THERAPEUTIC GAZETTE:

GENTLEMEN:—With all deference to you in other matters, I disagree with your views on diphtheria as stated in February number

of the GAZETTE. Let me repeat your own words, which I divide into three propositions :

"1. That all therapeutic interferences at present employed in diphtheria play little more than a palliative rôle, without in any way modifying the diphtheritic process itself, is unfortunately an undisputable fact with all clinicians and practitioners.

"2. To look for new remedies of the vegetable or mineral kingdom, or the products of the chemical laboratory, which might possibly exert a specific, or, at least, salutary influence over the affection, must at last prove a fruitless endeavor.

"3. Drugs do not and cannot cure diphtheria, and other measures must be thought of, unless we wish to abandon our patients wholly to the mercy of this dreaded foe."

I cannot accept these views. If I could I would cease practising medicine. I believe with Coleridge, that "in fact all medicines will be found specific in the perfection of the science."

I do not ask you to believe me, or to believe one hundred credible witnesses whom I could produce to attest it, but *I offer to demonstrate to you* at the bedside that the following is true of diphtheria in this section of country:

1. Diphtheria is at first a local disease in at least ninety-nine per cent. of cases. (In some two hundred cases observed I saw no exception.)

2. This local stage has a distinct duration of from twenty-four to seventy-two hours before stenosis or sepsis supervene.

3. No matter how malignant the outbreak, occurring uncomplicated in previously healthy subjects, every case can be speedily arrested and cured in this stage by "therapeutic (and hygienic) interferences."

4. The same means will save to the uttermost in the septic stage.

Yours fraternally,

T. J. HUTTON.

P.S.—As to the phrase "no matter how malignant," this may explain much of our difference of opinion. It may be that I have not seen the disease in its most malignant form here, for my experience with this malady is limited to this section. I have never known of more than eight children dying in one family during one outbreak here.

T. J. H.

[Although perhaps not as clearly expressed as might be, we thought we had succeeded in

making evident that the intent of the editorial, which is criticised in this letter, in stating that drugs cannot and do not cure diphtheria, is to refer to their internal administration. This intent is shown by the fact that the chief object of the editorial was to call attention to the importance of local medication in diphtheria. With this explanation, we still uphold the assertions of our editorial. Calomel may, of course, aid in curing diphtheria by removing or subduing the local inflammation; but it is the only drug which in our opinion has the slightest effect in curing diphtheria. All other remedies which are properly used in the disease simply help to keep the patient alive until nature succeeds in throwing off the disease. We believe that in the majority of cases diphtheria is a local affection, and that the local application may exert a direct curative effect. Especially has this seemed to us true of Monsel's solution. After all, however, in malignant cases the best local remedies have usually failed in reaching and directly affecting the parts, and therefore in killing the organism which we believe to be the cause of the disease. We must add, however, that we have never, as the result of our lack of faith in drugs, had a mortality of eight children in one family, perhaps thus showing that we have not met with the disease in its malignant form.—Eds.]

BERLIN.

(From our Special Correspondent.)

*THERAPEUTIC NOTES FROM THE CHARITÉ (the Berlin University Hospital)—HENOCH ON THE TREATMENT OF NEPHRITIS AND URÆMIA IN CHILDREN—THE TREATMENT OF DIPHTHERIA BY THE GALVANO-CAUTERY.*

The absence of any uniformly-adopted treatment in nephritis and uræmia in children, and the fact that every clinician has his own therapeutic measures, illustrates well the inferiority of our art to the *vis natura*.

The detection of albumen in the urine is an imperative admonition to put the child at once to bed, and to order a rigid diet, consisting chiefly of milk and bouillon. Meat, which strangely enough is directly recommended by some physicians, is positively injurious in every inflammatory condition of the kidneys. Unless diarrhœa be present, Henoch initiates the treatment with the following purgative, which he continues for two to three days :

R Pulv. hydr. mitis, gr. ivss;  
Sacchari albi, ʒi. M.

S.—Div. in chart. No. x., 1 powder every two hours.

In presence of diarrhœa the expectant treatment is advisable, for spontaneous healing of the nephritic process, simultaneously with the stoppage of the diarrhœa, frequently occurs after the use of bismuth and astringent enemata. After the above purge, Henoch orders Wildungen water to be drank copiously, and prescribes the following :

R Pot. acet., gr. xxx to xlv;  
Aq. dest., fʒiii;  
Syr. simpl., fʒvi. M.

S.—A dessertspoonful every two hours.

In very feeble and anæmic children the following combination is highly serviceable :

R Decocti cort. chinæ, fʒiii;  
Pot. acet., gr. xlv;  
Syr. cort. aurant., fʒvi. M.

S.—Dessertspoonful every two hours.

In numerous cases, with or without fever, digitalis may be exhibited with satisfactory results in the following manner :

R Infus. fol. digital., fʒiii;  
Sodii nitr., or pot. nitr., or pot. acet., gr. xxx;  
Syr. simpl., fʒvi. M.

S.—1 dessertspoonful every two hours.

From all these remedies, Henoch claims that he has never witnessed any unfavorable or irritating influence upon the kidneys. The potassium salt, though, ought not to be exhibited in too large a dose.

The employment of dry or wet cups over the renal regions will but rarely be called for, and only in cases in which urination is scanty or absent and considerable fever coexists. It is well known that venesection is at present a proscribed measure, but Henoch feels confident that he has sacrificed many a child by subscribing to the hæmophobic fashion of the day. Heim and Romberg recommended as the best "diuretic" in renal affections the abstraction of a cupful of blood; and, as assistant of the latter physician, Henoch states that he saw many a case, complicated with inflammation of internal organs, improving, which the modern therapist might have lost. But the majority of grave cases contraindicate venesection, and even wet cups, on account of the existing anæmia. Dry cupping may be tried, but it will probably not prove of great service.

Many physicians urge the employment of

warm baths and subsequent enveloping of the child in woollen blankets. Provided the intended powerful diuresis actually takes place, the baths have been very successful in Henoch's hands. In marked œdema, however, the diaphoresis will be either wholly absent or be very scanty, and even in absence of dropsy the baths proved a failure in quite a number of cases. In some cases of hemorrhagic nephritis an increase of the blood in the urine may even be noticed after each bath, so that they may have to be discontinued. Hence the bath can only be regarded as a trial-measure, the effect of which is to be watched for; still, the trial ought to be made even in complicated cases. In pneumonia their continued use has often led to good results. The hydropathic packing or compress, as exhibited so successfully in respiratory affections, appears of no service in kidney-lesions.

Now a word or two about pilocarpine, the fashionable remedy of the day, introduced by Demme, and praised so highly by many physicians. Henoch says he cannot join the eulogizers of this remedy, and has at present wholly abandoned its use. In order to get its diaphoretic effects it was often found necessary to push the dose up to  $\frac{1}{16}$  and  $\frac{1}{8}$  gr. (for hypodermic use), and vomiting and even threatening collapse were frequently observed. In a number of cases the pronounced depression of the cardiac energy forces the abrupt stopping of the pilocarpine injections. It is fair, however, to add that in some other cases, in which the injections could be continued with impunity for a week and longer and produce no diaphoresis, the dropsy was decreased, and the quantity of urine increased; its albuminous contents remained, nevertheless, stationary. In general, however, Henoch far prefers the warm bath as an equally potent and less dangerous medium of diaphoresis.

If these remedies do not occasion any improvement within a fortnight, astringents have to be tried,—tannic acid, or, if the urine shows considerable blood, ergotine. The latter remedy may be prescribed in the following formula :

R Extr. secal. cornut. aq., gr. xv;  
Aq. dest., fʒiii;  
Syr. simpl., fʒvi. M.

S.—A dessertspoonful every two hours.

If in a week the condition of the patient has not improved, the preparations of iron are indicated, especially in the hæmorrhagic form, but also in view of the anæmia invariably remaining behind after the completed cure. Henoch orders :

R Liq. ferri sesqui chlor., ℥iv;

Aq. dest., ℥iij;

Syr. simpl., ℥vi. M.

S.—Four times daily a dessertspoonful.

Still, all the above mentioned remedies cannot be regarded as prompt and quickly acting. Many weeks often pass, in spite of their continual exhibition, before a cure is wrought. Intercurrent uræmia calls for a great differentiation in the cases to be treated. The patients will be found to belong to either of two classes,—viz., the sthenic or asthenic,—either one of which requires a wholly different if not diametrically opposed treatment. In the former type of uræmia, where we deal with a vascular orgasm, the antiphlogistic treatment is quite in its place, while in the latter the cardiac weakness calls for stimulation of the system. Hence, in the sthenic type of uræmia, abstraction of blood (wet cups to the neck, six leeches on the temples or behind the ear), the ice-bag and a strong purge are called for, as follows :

R Infus. sennæ co., ℥i.

S.—A dessertspoonful every two hours.

If this purge be vomited, enemata, consisting of equal parts of vinegar and water, will be found useful. Great intensity and duration of uræmic convulsions may call occasionally for chloroform inhalations. But the onset of collapse symptoms (pallor of face, small, irregular pulse, coolness of the extremities) renders the immediate hypodermic exhibition of alcohol and camphor necessary.\* The formula for the camphor injection is :

R Camphoræ, gr. ix;

Spir. vini,

Aquæ dest., ℥ā ℥ lxxx. M.

S.—For hypod. use.

Henoch often also gives camphor by the mouth or by the rectum, and combines it with benzoine.

Following the recommendation of Pretorius, Henoch tried pilocarpine in nephritic uræmia, but lost the greater majority of cases under this treatment. Only three cases, where doses of  $\frac{1}{100}$  to  $\frac{1}{100}$  gr. were injected twice daily, recuperated after a copious diaphoresis.

In cases of what might be called artificial nephritis,—i.e., such as result from the injudicious use of medicine,—a somewhat different and chiefly symptomatic treatment is indicated. Henoch has seen such a nephritis

arising from turpentine, cantharides, tar, Peru balsam, tincture of iodine (one case of painting large surfaces four times daily), and carbolic acid (one case).

A syphilitic base may also be occasionally underlying a nephritic process, and of course must then be considered in the treatment.

Your correspondent was asked to assist at the first case of diphtheria treated in Berlin by galvano-cauterization. Following the instructions of Dr. Bloebaum, of Koblenz, Prof. Henoch was willing to give the new treatment a trial, and on the 9th of February applied the galvano-cautery to tonsils and pharynx of a diphtheritic child. "Though I think favorably of the cauterization plan," said Prof. Henoch to your correspondent, "I think Dr. Bloebaum's views require some restriction. In the first place, we are fully aware of the impossibility of executing this cauterization without chloroform, and then I can regard this cauterization only serviceable if executed during the first or first two days after the diphtheritic infection is established. If the pathogenetic microbes have once found their way to the circulation, and have there caused a deterioration or decomposition, I cannot see that even the local pharyngeal improvement—and this, of course, we obtain at all events—would save the child's life."

The child, about 7 years of age, was put completely under the influence of chloroform (ether is almost never used in Germany), the jaws separated by a screw-dilator, and the cauterizer applied three times,—one on each tonsil and once on the pharynx.

The child cauterized in the first week of February by Prof. Henoch for diphtheria is at present, ten days after the cauterization, in an improving condition. The aspect of the pharynx presented to your correspondent only a traumatic nature without a trace of any septic process. Unfortunately, a phlegmonous condition of a submaxillary gland keeps the fever high, so that it is as yet impossible to predict the termination of the case, though a favorable one is rather to be anticipated. The case does not seem to have been very suitable for the cauterization, as about six days had elapsed before the child was presented for treatment. It is probable, however, that only during the first few days of the diphtheritic infection can definite favorable results be expected from the galvanic cauterization.

The story of the "boycotted professor," Dr. Schweninger, has no doubt reached you by this time. It sounds like a little novel, of which the outlines are about as follows : Prof.

\* The combined hypodermic use of camphor and strychnine was tried by Henoch in the first week of February, 1886, and found to act well.

Oertel, of Munich, after a decade's hard study, constructs a thoroughly scientific method of divesting the system of an undesirable surplus of fat. Dr. Schweninger, hitherto wholly unknown in the medical world, annexes Oertel's cure as his, and loudly blows his "anti-fat horn." Bismarck, the mighty and weighty chancellor of the empire, consults Schweninger, and, by strict subjection to his orders, actually gets cured of his *embonpoint*. Next in order comes the appointment of Schweninger to a newly and especially created chair of dermatology at the University of Berlin. But, unfortunately, the moral credentials of Schweninger were not acceptable to the Berlin faculty; for Schweninger had been caught in *actu carundi cum femina in sepulchro maris ipsius*, and punished for this unspeakable crime. But Bismarck's dictatorial word soon subjected the refractory faculty, and Schweninger got his chair, though he is shunned and virtually boycotted by every professor and instructor.

#### BISMUTH IN INFLAMMATIONS OF THE MUCOUS MEMBRANES.

To the Editors of the THERAPEUTIC GAZETTE:

GENTLEMEN:—In your February number (in leading article) my attention was called to an article, "Bismuth Preparations," especially their use in inflammations of mucous membranes. Although limited, my experience with the drug has been satisfactory in all cases in which I have had occasion to use it, and in my opinion no other drug can take the place of it in mucous inflammations. But there is one preparation or combination I would like to call the attention of your readers to that I consider the best; it is the elixir of bismuth and hydrastia for cholera infantum. In first stage it is excellent, and I have found it valuable throughout the disease. And in gonorrhœa I have found it invaluable, with a few grains of sulphate of zinc. I first used it last summer in a case of gonorrhœa that had baffled me in every way; I first used it alone, then in combination with the zinc, with the most happy results. It is cooling, and does not cause any pain, simply coating over the mucous surface of the urethra, and allaying that burning sensation caused by urinating. Have also used it with some success in gleet. I should also state that I have it used just after urinating. Trusting this may be of some benefit to some of your readers,

I remain yours, etc.,

G. W. WHITELEY.

ALBANY, Mo., February 26, 1886.

#### Notes and Queries.

##### NOTES FROM THE CLINIC OF PROF. J. M. DA COSTA, M.D., OF PHILADELPHIA, AT THE PENNSYLVANIA HOSPITAL.

##### Contracted Kidney—Œdema of the Lungs.—

This case is that of a woman who presents a family history that seems to have a very decided tendency towards heart-disease. Indeed, if we can believe her story, her mother died of heart-disease, as did also all her brothers and sisters. They all suffered from dropsy, she says; but it is by no means sure that we can accept the history she gives. From her own history we glean that she has been always delicate throughout life, never robust and strong. Even in childhood she had rheumatism, and this has haunted her all through her life. Her feet have never been markedly swollen. For the past few months she tells us that she has passed more urine than she used to. Therefore we start out with the idea that this woman has never been very strong, and that she has had attacks of rheumatism, with spells of oppression of breathing. She came into the hospital on the 16th of February, stating that a few days before she had caught cold, and in consequence had suffered more than usual from oppression from breathing. While she was walking on the street she was seized with a very severe spell of oppression, with some dizziness and vertigo. By a strong effort she was able to walk home, but then, feeling so much worse, she came to the hospital.

On admission she was suffering from extreme dyspnœa, and both lungs were found full of fine bubbling râles, while there was also slightly impaired resonance, which was universal. The temperature was normal, as were also her bowels. When we examined the urine we found a slight amount of albumen, and some hyaline, granular, and epithelial casts, while the specific gravity was 1012. However, the most urgent condition demanding attention was the great dyspnœa. Remember that we found râles and the general disturbance that was caused by the embarrassment of respiration. When the heart was examined a mitral systolic murmur was found, followed by a distinct second sound. There was also a diffused, somewhat increased impulse, as well as a faint murmur heard at the aortic cartilage, which is so soft that it is probably due to anæmia. In truth, the cardiac lesion in this case consisted in moderate mitral regurgitation and some enlargement.

The temporals were also very prominent, and there was a condition of resistance of tension in both the radial and temporal pulse. Now to-day there are still some râles in the chest, but the percussion-note is clear, and she is not nearly so oppressed as she was. When she first came in, turpentine stupes were applied all over her chest, and she was given muriate of ammonium, five grains every half-hour, and two ounces of whiskey in milk. She was subsequently given Basham's mixture, and her improvement has been steady and marked. On the 20th (to-day) it is noted that her urine has a specific gravity of 1015, and there is still a trace of albumen. Now, as to the nature of the case. Her most prominent symptom is acute œdema of the lungs occurring in a woman who has some kidney-trouble and a slightly diseased heart. The most stress must be laid upon the kidney-complaint, because the mitral disease is not very marked, and because there is hypertrophy of the heart, which here seems to be rather due to the renal disease than a compensatory hypertrophy dependent upon the mitral lesion. While, therefore, there is undoubtedly some cardiac lesion, Dr. Da Costa regards the renal trouble as the more important. Now, as to the nature of this kidney-disease. When the low specific gravity, the tense state of the arteries, the varying quantity of albumen, and the condition of the heart are considered, they all point to contracted kidney, to parenchymatous nephritis, as does also the fact that dropsy has not been a marked symptom, for we usually do not have much œdema in this form of Bright's disease. It thus appears that we have in this patient undoubted kidney-disease, some slight derangement of the heart, oppression of breathing, and œdema that is due indirectly to the condition of the kidneys; for, though not the rule, it does sometimes happen that œdema will occur in contracted kidney, even when there is no disease of the heart. All kinds of rapid effusions, such as œdema of the lungs and the like, especially where they are apparently inexplicable, are very frequently due to Bright's disease, and most commonly to interstitial or parenchymatous nephritis. What used to be called serous apoplexy is frequently due to kidney-disease; indeed, nine out of ten such cases are so caused. So, also, we may have serous effusions into the pericardium, caused in the same way. Of course, we may have œdema of the lungs from heart-disease, but it is more frequently due to a contracted kidney.

So much, then, for the diagnosis and etiology in this case. What does the most good in these cases is vigorous counter-irritation by the use of turpentine and dry cupping all over the chest, and the internal administration of ammonia. Whether we use the aromatic spirits,  $\frac{1}{2}$  drachm every half-hour or so, or the muriate of ammonium, which was used here, it proves a very valuable aid to the counter-irritation. The heart also needs stimulation, for the circulation is very much embarrassed, and for this purpose we are called upon to give moderate doses of alcohol. The patient has improved very much, and, the urgent symptoms having passed away, we will now direct our attention to the condition of the kidneys. She will be given Basham's mixture, and her diet shall be made up largely of milk, though she will not be restricted exclusively to it.

*Gastro-Intestinal Catarrh causing Enlargement of the Liver.*—This woman, 24 years old, has a good family history. She herself was well until September, 1884. Then she was taken with pleurisy, was in bed for a few days, when she got up, but during the whole winter she had more or less trouble from the pleurisy. Frequently since that attack she has been troubled with vertigo, nausea, and vomiting. Last December she was seized with a more severe attack of vertigo, nausea, and vomiting, which has continued quite persistently ever since. She has also been very costive, and has suffered greatly from headache. When she came into the hospital she complained of intense occipital headache, her tongue was coated, and her heart and lungs were normal. The area of liver-dulness was increased and her bowels were very costive. Her temperature was normal, but her stomach would retain nothing; all food was immediately rejected. The urine was alkaline, had a specific gravity of 1012, and contained neither sugar, albumen, nor casts. She was at once placed upon small doses of calomel with bicarbonate of sodium and a milk diet. Under this treatment she improved rapidly, and is now much better in every way, save that the occipital headache still persists and that her bowels are very sluggish, which condition seems very hard to overcome. There is not now nor has there been at any time any jaundice. The tongue is heavily coated with a yellow coat; the gums are normal, perhaps they are slightly swollen. There is, upon examination, some slight soreness on pressure about the pit of the stomach, and there is still some occasional vomiting, the vomited

matter being very sour. The stools are hard and dark. It appeared at first that there was some tenderness over the region of the liver, but, upon more careful examination, it was found that this soreness is confined to the region of the stomach and bowels. She has had no cough, and there is no heart-lesion. There is no pulmonary dulness, and the respiratory murmur is normal, but on the right side there is dulness from the scapula to the lower extremity of the ribs, which is, however, due to an enlarged liver. Why is it not due to a pleuritic collection? That this distinction should be made is very important, and the way to do so is very simple. If the dulness were due to a pleuritic effusion forced inspiration would make no difference, but as it is due to the liver there is resonance because the forcible action of the diaphragm forces the liver downwards, and the space occupied by the expanded lungs is greater than when it is less full. By this process, which we can call respiratory percussion, simple as it may seem, we can always tell the difference between dulness from pleurisy and that from hepatic enlargement. It is very important that we should resort to this crucial test, because from the history of the case alone we would be justified in supposing that the dulness was due to pleurisy. Well, now, what is the matter with the girl? We have evidently an enlarged liver, and we have gastro-intestinal catarrh. It may be asked whether these conditions could cause the nausea and vomiting, the vertigo and headache, and it can be answered that they certainly could. Such reflected cerebral symptoms are not at all uncommon, particularly in women. Gastro-hepatic derangements will frequently cause headache, vertigo, roaring in the ears, and sleepless nights. While such symptoms are apparently cerebral, they are rarely of abdominal origin. Well, now, what was the cause of the enlargement of the liver? This is not so easy to determine. The girl has led a temperate life, and there is no reason to suppose that the enlargement is due to any excess. At the first blush, such marked enlargement of the liver would suggest cancer, but if there were cancer we should surely have tenderness all over the region of the liver, which we do not have here. Moreover, a cancerous liver is usually enlarged downwards, and the enlargement is irregular in outline, while here the enlargement is upwards and the margin of the organ is felt to be smooth. We had one case in the house here where a congested liver presented such

a great enlargement that we were for a time quite sure that we had to do with a cancer, but under appropriate treatment the enlargement all disappeared. Well, then, if it is not cancer, what is it? Dr. Da Costa believes it is one of those cases that we occasionally meet, where we can make the diagnosis of fibroid enlargement of the liver and slight fatty degeneration. Such cases are not infrequently the result of long-continued gastro-intestinal catarrh. The liver first becomes congested, then harder, and finally undergoes fatty degeneration in places. It is hard to give an appropriate name to this condition: the older writers used to call it chronic hepatitis, which is to a certain extent correct, for the condition really grows out of a chronic inflammation. That we may be enabled to recognize this condition of the liver, Dr. Da Costa would emphasize the fact that in nearly all cases, besides the physical signs which we have here noted, there is also gastro-intestinal catarrh, which in this case was the primary trouble. The absence of jaundice is striking in view of the fact that the symptoms are from the liver, and yet it must be remembered that it is not usual to have jaundice unless there is great involvement of the hepatic cells, therefore we should not be misled in diagnosis by the absence of this symptom.

As already said, she has taken small doses of mercury with some benefit. She is better; but she is not well, for there still remains the tendency to headache, nausea, and vomiting; she is costive, and her tongue is still coated. Well, now, shall we go on with the calomel? As she has been using it since the thirteenth of the month, and as her gums are a little touched, it would seem better that we stop it and see what we can do with other remedies. Dr. Da Costa's experience teaches him that one of the very best drugs when the portal circulation is affected, when there is enlargement of the liver from congestion, is the phosphate of sodium; in the case to which he referred a short time ago, where he at first thought that he had to deal with cancer, its effects were very good. He strongly recommends it in such cases when they are non-malarial, but arise from a persistent congestion. Dr. Da Costa prescribed for this girl one drachm of the phosphate of sodium (in warm water) thrice daily on an empty stomach. It is better borne when given in warm water. It will sometimes act as a laxative, and if it does so excessively, the dose must be reduced. In addition to this internal medication, he recommended painting over the surface of

the liver with tincture of iodine diluted to one-half its strength. This girl's diet so far had consisted of milk and soups; this had been well retained save during the last twenty-four hours, when she vomited. She has had no solid food. She was directed to take a quart to three pints of skim-milk with lime-water (in the proportion of half an ounce of lime-water to four ounces of milk), and will also let her have the soup, and a few stewed oysters occasionally. All starchy articles must be rigidly excluded from the dietary. As she improves, she will be allowed to have some underdone meat; but it will be a long time before she can be allowed to use a mixed diet, and particularly any articles containing starch or sugar.

#### SURGICAL DIAGNOSTICIANS IN ROUMANIA.

The *Deutsche Medizinische Zeitung* of January 14, 1886, brings a story which is a poor compliment to our Roumanian colleagues. A peasant woman, 25 years of age, mother of seven children, had no coitus with her husband, for some reason or other, for the last four years. Nevertheless, she becomes pregnant, complains of great abdominal pains, and, feeling convinced that it is a tumor, is sent by her husband to a hospital in Jassy. The diagnosis of "cystosarcoma of the right ligament" having been established, the woman is placed on the operating-table, and laparotomy performed. The result of this unfortunate diagnosis and operation was the appearance of a child of seven months, which lived a few hours, while its mother succumbed on the seventh day after the operation. Official inquiries having elicited these facts, the surgeons were punished.

#### POISONING FROM THE EXTERNAL APPLICATION OF ACONITE.

DR. HERMAN GASSER, of Platteville, Wis., writes to the *Medical Record* (February 27, 1886) that he was called to see a druggist who was suffering from rheumatism in the feet. The patient had been employing tincture of aconite as an external application, and had used up an ounce in this way in three days. As he was no better, Dr. Gasser ordered the discontinuance of the aconite, and gave him salicylate of sodium and colchicum internally. On the following morning he was much better and took a hot foot-bath, keeping his feet immersed (without rubbing) for about half an hour. At the end of this

time he began to feel so "very peculiar" that the writer was sent for. He found him sitting in a chair, and complaining of tingling sensations starting from the hands and feet and extending over the entire body, and of nausea. The pulse was weak and slow, and the skin was cool and moist. As he was growing worse and was vomiting frothy mucus, he was put to bed, and hot-water bottles were applied to his body. Although he had taken no aconite internally, the symptoms were unmistakably those of aconite-poisoning, and Dr. Gasser was about to give him a hypodermic injection of brandy and digitalis over the heart, when he was taken with a spasm, made a few jerking efforts at respiration, and then seemingly died of syncope. The heart had apparently ceased to beat, and pulsations could be detected neither by the writer nor by Dr. Buck, who was present. Although without hope of restoring the patient, the hypodermic injection was nevertheless given, partly for the reason that it was prepared. In about a minute he began to gasp for air and the heart could be felt to beat. The injection was then repeated, hot wet cloths were laid over the heart, and an enema of brandy and digitalis was given by the bowel. Reaction was soon fully restored, the pulse and respiration became strong, and the skin warm, red, and covered with perspiration. This was followed by spasms, which were controlled by morphine and ether, and the patient then passed into a restless sleep, from which he awoke conscious, but dull. The following morning, though feeling rather stupid, he arose and ate breakfast with his family. Dr. Gasser offers the following explanation of the occurrence of poisoning:

"Tincture of aconite is a resinous solution in alcohol, and as fast as it was applied to the skin the alcohol evaporated, and the aconite was deposited like a coat of varnish on the skin. (The limbs were bathed with it from the knee down.) The hot-water soaking caused a congestion and softening of the skin, and put it in the best possible condition for absorption."

#### TSUCHIAKABI.

This drug is the fruit capsule of an orchid indigenous in Japan, and used there for a long time past. The capsules possess an acid and bitter taste, and contain a substance which is largely soluble in water. By treatment with spirit, an extract can be obtained which has a sharp but not unpleasant taste. It is com-

posed of a resin, acid and glucoside, to which are probably to be attributed its medicinal properties. The urinary bladder and passages are the parts of the body on which the medicament exerts its special action. The Japanese employ a watery extract of this drug, which would be administered in those cases for which cubebs and copaiba are prescribed, with the advantage of the absence of the disagreeable odor of the last-named drug.—*London Lancet*, January 2, 1886.

#### A NEW PREPARATION OF SPARTEINE.

An improved process for the preparation of sparteine has been recently laid before the Société de Biologie by MESSRS. HOUDÉ and LABORDE (*Rep. de Pharm.*, December, 1885, p. 533). It consists in exhausting in a displacement apparatus the leaves and branches of the spartium scoparium, reduced to a coarse powder, with sixty per cent. alcohol, filtering, distilling off the alcohol in a partial vacuum, dissolving the residue in solution of tartaric acid, filtering to remove a greenish, gelatinous matter, consisting principally of chlorophyll and scoparine, making the acid solution alkaline with potassium carbonate, and then shaking it several times with five or six times its volume of ether, which removes all the alkaloid. This is purified by repeating several times the treatment of dissolving in solution of tartaric acid, neutralizing, and shaking the alkaloid out with ether. In this way about three grammes of the active principle may be obtained from one kilogramme of the plant. Sparteine is described as a colorless liquid, heavier than water, containing no oxygen, and boiling at 278° C. It has a rather pungent odor, recalling that of pyridine, a very bitter taste, and when exposed to the air, turns brown and becomes of a thicker consistence. It is soluble in alcohol, ether, and chloroform, and insoluble in benzine and petroleum oils. Sparteine is an energetic base, and readily combines with acids to form salts that crystallize readily, the sulphate occurring in large, transparent, very soluble rhombohedra.—*Pharm. Journ. and Trans.*, December 26, 1885.

#### THE PRACTICAL USES OF LANOLIN.

From his investigations of the composition of the cholesterine fats found in keratinous tissue, DR. OSCAR LIEBREICH (*Brit. Med. Journ.*, February 13, 1886) conjectures that the absorption into the skin would be best in

the case of those fats which have their origin in keratin-bearing substances, as hair, epidermis, etc. The old theory that the skin was only oiled from glandular secretion did not harmonize with these researches; and lanolin, upon his suggestion, is now being tested as to its efficacy in therapeutics as a new basis for salves and ointments. It possesses such peculiar properties, also noticed by Berthelot, that it becomes a matter of necessity to give a number of formulæ, in order that the druggist may more easily compound and dispense the remedy. It is also of importance to add other ingredients to make it more pliant, as it is a too sticky mass in itself to be employed alone; and from the many trials which Dr. Liebreich has made with different substances, as vaseline, paraffine, ointment, glycefin, oils, and fat for this purpose, he has found the latter by far the best, as the others generally interfered with the absorbing qualities of lanolin.

He also states that the many substances, under the name of pure wool fat and wool oil, which have found their way into the trade before and since the introduction of lanolin, are injurious, as they contain free acids and various animal substances.

Dr. Liebreich suggests the following tests for its purity in therapeutics:

1. A small quantity, on being heated in water over a water-bath, must show the absence of glycerin.
2. If a solution of caustic soda be added, ammonia must not be developed.
3. The fat, if a small portion be heated with water on a water-bath, must separate in oily drops without producing an emulsion. If the quantity employed be large, it must separate as a clear oil.
4. With blue litmus-paper the reaction must not be acid.
5. For examination, if it be mixed or well rubbed with water upon a ground-glass plate with an iron spatula, the result must be a product containing over one hundred per cent. of water; and if the lanolin employed be pure, the kneaded mass will be sticky and paste-like, to which the spatula readily adheres; but if impure, the mass will have a soap-like smoothness, from which the spatula readily glides.
6. On exposure the upper surface of lanolin and all lanolin salves and ointments becomes darkened, due to the evaporation of water, and not to its decomposition.
7. It never becomes rancid, and its smell should remind one of wool.

Dr. Liebreich's experience with the remedy, with that of other physicians, has been but limited, yet he does not hesitate to pronounce the results so far obtained most promising.

The first question which presented itself was whether the skin would bear it well. From its use in over four hundred cases in the hospital and private practice of Dr. Lassar, the dermatologist, no irritation of the skin was ever produced, a result which his own experience, during the years in which he has been experimenting with it, confirms. For this reason alone it is to be highly recommended for massage.

It is true, it is not as smooth as vaseline, but it has the advantage that the skin, after being rubbed dry with a cloth, still remains soft and pliable.

In cases where the epidermis is fissured, as, for instance, in chapped hands, it may be advantageously employed as follows :

The parts affected, particularly the hands, are to be well washed with some good soap, and then to be thoroughly rinsed with water. Upon the moist surface a small quantity of the ointment is to be well rubbed in, and the parts afterwards to be wiped with a dry towel. The skin is left soft and supple, on account of the rapid absorption and retention of the lanolin, and, what is more remarkable, the hands are not greasy, yet the water flows from them as if oiled. Accordingly, it may be especially useful for the hands of surgeons and obstetricians. Hands thus treated show a greater resistance towards cold and water.

The influence produced upon the skin in seborrhœa sicca is remarkable. On combing the hair with a fine comb the scales disappear rapidly.

In pruritus ani he has used lanolin with sulphur with admirable results.

Dr. Lassar, in his polyclinic for skin-diseases, has found that psoriasis heals very easily and quickly, and without irritation, through the use of a twenty-five per cent. lanolin-chrysarobin ointment. It remains for the future to determine whether in all cases equally favorable results will be reported.

#### CASE OF POISONING WITH OIL OF AMBER.

In the *Vierteljahreschrift für Gerichtliche Medizin und Öffentliches Sanitätswesen* (vol. xliii. p. 267) we find the report of a case of intoxication with oil of amber, a remedy which in Eastern Prussia enjoys great popularity as an abortive medium. A woman, 30 years of age, took with suicidal intentions a tablespoonful

of the oil of amber, and was soon seized with violent vomiting and diarrhœa, attended by a considerable rise of temperature. She happened to be pregnant, and aborted soon after ingestion of the drug, while the symptoms of a general intoxication grew more and more intense. The general morbid symptoms recalled greatly those of typhoid fever. The woman, however, being of a strong constitution, revived.

#### PEPTONATE OF BISMUTH.

LANG tried the peptonate of bismuth in a case of gastralgia becoming paroxysmal several hours after a meal, and depending probably upon a duodenal ulcer. After all known standard remedies had failed, Lang was not surprised to find that this drug (given in drachm doses) could not bring any relief either.

#### A CASE OF POISONING BY CASTOR BEANS.

The ricinus communis, more familiarly known as the castor-oil plant, is quite frequently cultivated in our flower-gardens, especially among the Germans, and but little attention is paid to the danger of the ill effects that may originate from the ingestion of the seeds. The United States Dispensatory states that two of the beans will cause serious vomiting and purging, and three have taken the life of an adult. This statement would startle the laity, since their children during play-hours have abundant opportunities to take advantage of this source of poisoning.

DR. S. E. EARP (*Cincinnati Lancet-Clinic*, Feb 6, 1886) reports the following case of poisoning with these seeds which is worthy of being noted not only on account of the severity of the symptoms, but the rarity with which a similar condition is met in practice.

On the afternoon of May 13, 1885, E. D. Ferboss, aged 52 years, and by occupation a conductor on the I. B. and W. Railroad, purchased a small quantity of castor beans to plant in his door-yard for the purpose of ornamentation. After preparing the ground for the reception of the seed, and removing the capsule of the beans, he accidentally put one or two in his mouth and unconsciously crushed them with his teeth. The prompt action of the salivary glands and the sweetish nature of the substance made the taste rather agreeable, and he was induced to eat ten of the beans before his appetite for them was gratified. The time at which the stomach received the seeds was 3 P.M., and no uneasi-

ness whatever was experienced until 5.30 P.M., which was thirty minutes after he had eaten a hearty supper. At this juncture the face became flushed; a tingling sensation of the skin, confusion of ideas, and intense abdominal pain were prominent features. At 6.30 emesis was violent in the extreme, and each effort brought forth large quantities of mucus mixed with blood. An hour later the symptoms became more aggravated, and the bowels moved frequently with bloody stools, attended with great pain and tenesmus. A messenger was despatched for Dr. Earp, but owing to his delay in finding his office he did not see the patient until ten o'clock, at which time some of the above symptoms had subsided, but the purging and vomiting, with increased abdominal pain, continued. The temperature was 96° F., the pulse 60, and the skin, cold and clammy, was bathed in perspiration. The patient could not give an intelligent history of his case,—in fact, appeared rather stupid, and his memory was unreliable. Tympanitis and abdominal tenderness were well defined, and the muscles of the throat and chest were tender to the touch from the long-continued emesis, and the situation seemed to indicate that collapse was not far distant. Dr. Earp administered  $\frac{1}{8}$  grain of morph. sulph., 10 grains of bismuth. sub. nit., and 2 grains capsicum pulv., and ordered dry heat applied to the extremities. No drug-store being located in the vicinity, he was compelled to depend upon his pocket medicine-case, and therefore gave small doses of carb. of ammonia rather than the aromatic spts. of ammonia. After the second administration of the above combination the patient began to react, and when the doctor left his bedside, at 1.30 A.M., he was resting somewhat better. Dr. Earp instructed the attendant to continue the same treatment at intervals of two to four hours, as necessity demanded. He saw the patient again at 10 A.M., and his temperature was 102° F., pulse 90, tongue heavily coated, and skin dry and harsh. The bowels had moved only twice since daylight, and although the vomiting had ceased there still remained some nausea. The patient complained of a general soreness of the muscles, but continued to improve, and at the end of a week was able to leave his bed.

#### NITRO-GLYCERIN.

Among the errors of the last British Pharmacopœia the ordering this drug to be dispensed in chocolate tablets is perhaps the worst. Not only is the dosage uncertain

and the manipulation required dangerous, but this method of administration is slower in action and exceedingly expensive; in fact, it is difficult to conceive why the compilers of the last edition of the Pharmacopœia should have gone out of their way to choose so inconvenient and impracticable a vehicle when the one per cent. solution of the drug, which has been in general use for a considerable period, was open to them. It is stable, easily gauged, and prompt in action, and has in fact all the merits which are conspicuous by their absence in their present formula. The tablets in question are not stamped, and bear no indication of their nature or strength, and mistakes which might be dangerous in their results may easily occur.—*Medical Press*, January 13, 1886.

#### POISONING BY BENZINE.

DR. A. N. KAZEM-BEK reports the very rare occurrence of a case of fatal poisoning by benzine (*Indian Med. Journal*, January, 1886). The case was that of a retired soldier, an habitual excessive drunkard, who had mistaken benzine for vodka (aqua vitæ), and drank 3 drachms of the fluid. Though sober at the time, the patient did not discover his mistake, since he had absolute loss of smell and taste (as may be seen from the fact of his having taken with relish several glassfuls of an infusion of horse excrements, which his relatives had given him as vodka on several occasions with curative aims in view). In about ten or fifteen minutes the patient lost consciousness. Two hours later the author found him in a comatose state, with reaction less, slightly dilated pupils, insensible cornea, general anæsthesia, trismus, irregular, stertorous breathing, hardly perceptible pulse, coldness of the body, paralysis of all four limbs, great distention of the belly; later on, myosis of an extreme degree (as if from opium) appeared. The patient died in a comatose state about seventeen and one-half hours after the ingestion of the poison. The exhalation of benzine by the lungs was so intense as to produce extreme giddiness in the author (after four hours' stay with the patient), and nausea with vomiting in the patient's brother. At the post-mortem examination there were found congestion of the meninges, sinuses, and the ependyma of the ventricles; accumulation of serous fluid under the pia mater and in the ventricles; congestion of the pharyngeal, laryngeal, and tracheal mucous membranes, and of the lungs; about

an ounce of dark fluid in the right cardiac ventricle; chronic catarrhal changes in the mucous membrane of the œsophagus, stomach, and intestines; finally, an odor of benzine in all the organs and cavities of the body. The author concluded that death was caused by asphyxia. While pointing to the absence of any characteristic lesions, he expresses his belief that the specific odor which permeates the whole body is the single criterion for recognizing a case as that of benzine-poisoning.

#### COCAINE IN OINTMENTS AND SUPPOSITORIES.

Cocaine being insoluble in oily and fatty substances, it is advisable, in cases where it has to form an ingredient of a pomade or suppositories, to first dissolve it in oleic acid, and afterwards to add the other substance to it by small quantities at the time. Treated in this manner the cocaine will assimilate itself with the greasy substance, and a homogeneous preparation will be obtained.—*Druggists Circular*, February, 1886.

#### MILK TESTING.

Those who are called upon to test a large number of samples of milk, in a rapid yet exhaustive manner, will find the following simple method invaluable. The apparatus used is a stoppered burette of 100 c.c. capacity, with a glass tap at bottom. The solutions necessary are a solution of one part of caustic soda in two hundred parts of rectified spirit, a solution of one part glacial acetic acid in two parts of distilled water, and Fehling's solution; also pure ether. Into the burette are poured, first 20 c.c. of the alcoholic solution of soda, then 20 c.c. of milk, then 25 c.c. of pure ether. These are then well shaken together and allowed to stand at rest for six or eight minutes. Two layers will result. The lower one is then drawn off through the glass tap. In this we have the sugar of milk (lactose) and the casein. The ether layer remaining in the burette contains all the butter. The amount of butter is obtained by evaporating this in a tared porcelain, glass, or platinum dish. In the other solution the casein is estimated by making up the 200 c.c. with distilled water and precipitating by means of 2 c.c. of the acetic acid solution. The liquid being then passed through a tared filter, the separated casein is retained, and may be dried and weighed. The filtrate contains the sugar of

milk, or lactose, which may be readily estimated by Fehling's solution. The whole of these estimations is easily performed in less than two hours. At the commencement of this process, 20 c.c. of the milk should have been acidulated with 1 c.c. of the acetic solution, and set on a water-bath to evaporate, and finished in a hot-air bath. This being done in a platinum crucible, the dry residue, after weighing for total solids, can be ignited, and the weight of ash determined. The complete analysis, giving butter, casein, lactose, ash, and water by difference, is thus obtained within two hours, the results, with ordinary care and skill in manipulation, being most reliable.—*Pharmaceutical Record*, February 1, 1886.

#### THE MECHANICAL ACTION OF DRUGS.

This subject, which has been too long neglected, has lately inspired the researches of more than one inquirer. M. SCHUTZ's experiments and results are extremely interesting, as may be judged by the following description of one series of them only: From healthy living dogs the stomachs were carefully excised, and suspended in a glass chamber filled with moist air at 37° C. (98.6° F.), when the so-called spontaneous digestive movements propelled all contents towards the pylorus, frequently continued for periods of from thirty to one hundred minutes. Inquiring into the action of weak solutions of various alkaloids, etc., upon this gastric activity, M. Schutz finds that distinct and chronic spasms are produced by digitaline, helleborine, muscarine, physostigmine, and scillaine; increase in the number and velocity of the movements was caused by apomorphine, caffeine, emetine, nicotine, strychnine, tartar emetic, and veratrine; while atropine, chloral hydrate, cocaine (as might have been anticipated), nicotine (in larger doses), and pilocarpine, quickly stopped these motions, or greatly diminished their activity.—*Medical Press*, January 13, 1886.

#### PECULIAR IDIOSYNCRASY WITH REGARD TO QUININE.

Quinine is always supposed to reduce the temperature, and yet DR. MOECKEL, of Nuremberg, refers to a case in which a woman, after taking 3 grains of quinine for malaria, had a chill and a rise of temperature up to 104.5° F. It is stated that this increase of temperature occurred every time quinine was administered.

### A STUDY OF THE PHYSIOLOGICAL AND THERAPEUTIC EFFECTS OF ADONIDIN.

BY HOBART AMORY HARE, M.D. (UNIV. OF PA.).\*

THE adonis vernalis has for many years been used empirically in Russia as a remedy for all forms of cardiac failure; but until the clinical observations of Buhnow, of St. Petersburg, were made in 1879 nothing was known of the action of the drug.† In

1882, Vincenzo Cervello, of Strasburg, made a limited research in regard to its action on man and animals, and it is to him that we owe the discovery of the glucoside, the effects of which this paper describes.‡ Following these researches came those of Lesage in 1884, which were carried out in the laboratory of Germain Sée at the Hôtel Dieu. In the same year Durand, of Paris, published his elaborate monograph, entitled "De l'Action Comparée des Médicaments Cardiaques," in which he gives the results of a number of clinical studies of great value.

Almost at the same time there also appeared in the *International Journal of Med-*

\* Physician to the Children's Dispensary of the University Hospital and to St. Clement's Dispensary.

† St. Petersburger Medicinische Wochenschrift, January 6, 1879.

‡ Archiv. für Exp. Path. and Pharm., t. xv., 1882.

*ical Sciences* a clinical article\* by Dr. Gastano Traversa,\* and another elsewhere by Dr. Gluzinski,† in which the virtues of adonis vernalis and its glucoside were highly praised.

Still more recently, Huchard presented, on December 23, 1885, in the Société de Thérapeutique, cardiographic and sphygmographic tracings taken from persons under the influence of adonidin, and also described the effects produced in the rabbit when the drug is given hypodermically. Lastly, Dr. J. C. Wilson, of Philadelphia, has published a paper in the *Medical News* for January 2, 1886, on the action of the drug.

As nearly all the observers mentioned have confined their researches more to the purely clinical aspects of this medicament than to a study of its physiological properties, and as they all report such favorable results from its use at the bedside, it occurred to me that a thorough experimental research on the physiological action of the remedy might be of value, and to this end the following experiments were performed.

If the heart of a normal frog be cut out and placed in a solution of adonidin of the strength of 2 grs. to the ounce, the movements are for a moment more rapid than before, but soon become slower. Under these circumstances the cardiac movements become slow, not because diastole or systole is prolonged, but because the cycle of cardiac movement is imperfectly performed, the heart-muscle seeming too weary either to contract or expand. When the same solution is placed in the pericardial sac of a frog, the centric nervous apparatus being left untouched along with the circulatory system, previous to the increase of rate seen in the isolated heart comes a short stage, in which the cardiac movements are slowed, apparently by pneumogastric stimulation, for the diastolic pauses are the portions of the cycle which are prolonged. Along with this slowing, the heart-muscle contracts much more thoroughly, and arterial pressure is increased, for the blood-vessels in the mesentery of a frog can be seen to decrease their lumen. Soon, however, the inhibition of movement seems to be removed or overpowered, for the pulse-rate is increased greatly. This condition of rapid movement continues for a short time, and finally the heart again becomes slow, with the slowness of weakness, the movements being like those

already described in connection with the isolated heart. In both the isolated heart and the heart *in situ* diastole ends the scene. Two questions now arise: namely, what is the cause of this stoppage in diastole, and what produces the slowing of the cardiac rate occurring in the heart when lying in its sac.

The diastolic arrest of the isolated heart can only be due to one of two things,—either the inhibitory cardiac apparatus is stimulated, or the heart-muscle and its motor ganglia are depressed. The latter seems far more likely, not only from analogy but from the fact that in the experiments performed on the non-eviscerated heart of frogs, the inhibitory nervous apparatus was found to be stimulated centrally and not peripherally; and furthermore, the very character of the slowing of the isolated heart showed it to be due not to stimulation but to increasing depression.

That the vagi are not stimulated peripherally by this drug at any time was proved by the following experiments, and also by the results of the observations on the action of the drug upon dogs, which will be described farther on.

If the inhibitory nerves be cut before the adonidin is placed in the pericardial sac, the usual increase in rate under such circumstances takes place, and the addition of a small quantity of the drug now immediately increases the rate still further, without the appearance of any primary stage of slowing of rate. This proves that the primary slowing occurring when the vagi are intact must be due to exaltation of their function, and also proves that the drug must directly stimulate the heart-muscle; for the rapid rate under these circumstances is not one of weakness but of power. It should not be forgotten that this drug in large quantities finally stops the heart in diastole, whether the vagi are intact or divided. In small quantities it does not produce the primary slowing of the pulse, nor does it bring on the peculiar weak and imperfect movements which have already been described as occurring before death. In other words, it requires large doses to affect the pneumogastric, and large doses to depress the heart-muscle.

One more point is to be decided. Is the rapid stage following the primary slow stage in the viscus *in situ* due to paralysis of the vagi, to direct stimulation of the heart which overcomes inhibition, or to both? While I am unable to state whether over-stimulation takes place, it is a fact that the pneumogastric nerves are certainly in this second stage de-

\* Medical Times and Gazette, October 21, 1885.

† Quoted by the THERAPEUTIC GAZETTE, July 15, 1885, p. 475.

pressed by the drug, for galvanization of these nerve-trunks during this stage failed to produce as marked a slowing of rate as should have occurred, provided the inhibitory pathway was open. From this point we may conclude that although the stimulation of inhibition in the first stage is centric, the paresis of inhibition in the second stage is peripheral. The same changes are present when the drug is injected into the posterior lymph-sac of a frog. The animal soon becomes passive and immovable, and dies shortly, so quietly that its death is not noted until he is handled.

That the high arterial pressure produced by this drug is due in part to centric stimulation of the vaso-motor system is proved by the fact that the mesenteric blood-vessels are seen to dilate after section of the spinal cord. Further evidence of this fact was adduced when studying the influence of the glucoside on the circulation of mammals, for there is but little, if any, difference in the action of adonidin on the dog and frog.

The injection of the quarter of a grain of adonidin into the jugular vein of a dog, weighing twenty-five pounds, causes a great increase of cardiac force and arterial pressure, and a marked decrease in pulse-rate. Following this stage of exaltation of force and pressure comes a marked fall of arterial tension, and, as is usual, a decrease of pulse-force, with an increase of pulse-rate. This condition remains the same for some time, until at last the heart beats irregularly, and stops in diastole, just as did the heart of the lower animals. We have, therefore, several stages to be accounted for in the action of this drug on the dog, viz., the increase in arterial pressure in cardiac force, and decrease in pulse-rate, in the first stage; the fall of arterial pressure and force, and increase of pulse-rate, in the second stage; and the arrest of the heart in diastole at the end of the third stage. Turning attention to the rise in arterial pressure, the writer eliminated all danger of a rise due to asphyxia by curarizing the dog, artificial respiration being maintained. Under these circumstances arterial pressure was increased as greatly as when the animal was not curarized. What, then, is the cause for this rise in arterial pressure? Probably two factors lie at the bottom of this condition, namely, centric vaso-motor stimulation, aided by increased cardiac force, for when the spinal cord was divided high up in the cervical region, thereby producing vaso-motor palsy, the rise in pressure under the influence of adonidin was of course less marked, and the rise

which did occur must have been due to increased cardiac force.\*

The experiment on the fourth dog was made to discover how the slowing of the pulse was produced in the first stage. One-fourth grain of the drug was administered in the same manner as before, the animal having first been curarized. No sooner was the slowing of the heart-beat most marked than the vagi were divided, and instantly the pulse was increased from 102 to 192 per minute, proving that the slowing was due to stimulation of inhibition, and that this stimulation was centric. The increase in force has already been shown to be due to a direct stimulant action of the drug on the heart itself.

In regard to the symptoms of the second stage, we find that the fall of arterial pressure is due to palsy of the vaso-motor system, since, when the cord is intact, galvanization of the sciatic nerve or asphyxia did not bring about increased pressure.

The decrease in pulse-force is due to the depressing action of the drug on the heart itself, as is also the arrest in diastole. The increase in pulse-rate is due to inhibitory failure, for in the dog, as well as in the frog, galvanization of the vagi failed to slow the heart.

In the next experiment the dose of the drug used was much smaller than before, since it had become evident that the larger doses were absolutely toxic in their character. An eighth of a grain was, therefore, injected into the dog's jugular vein, curare and artificial respiration being used. As a result, I found that in small doses this glucoside does not cause any primary slowing of the heart, but increases its frequency, its force, and the arterial pressure from the first, all three of these features being permanent and constant under the smaller dose. Even with this dose, however, the animal died. A twelfth of a grain given slowly to a large dog did not produce death nor a primary slowing in rate, but seemed to increase rate, force, and pressure. In this last experiment no tracing was taken, the jugular vein only being exposed.

I should have stated before that when I poisoned a small dog by a large dose of adonidin there were symptoms of nausea and intestinal spasm, accompanied by the expulsion of fæces. The animal had no convulsions or spasms, but lay on its side, with pupils widely dilated. When death occurred, respiration

\* That the cord was thoroughly divided is proved by the fact that asphyxia failed to cause any rise in pressure.

continued some moments after the heart stopped.

#### ACTION ON THE NERVOUS SYSTEM.

When an eighth of a grain of adonidin is injected under the skin of a medium-sized frog, in a few moments he becomes drowsy and disinclined to move. When a jump is attempted it is incoördinated and clumsy, and a succession of leaps is of rare occurrence. Pricking with a pin now fails to produce any reflex drawing away of the leg which is irritated, and in the course of five minutes following the administration of the drug he permits the foot to crackle in the flame of a gas-jet. That this is not due to a loss of power is proved by the fact that if the amphibian so wills he can leap from place to place, and we therefore must conclude that paralysis of sensation has taken place somewhere in the course of the afferent nervous system. That this effect of the drug is on the sensory tract of the spinal cord is proved by the fact that if the artery of one leg be tied and the poison given above it, each leg fails to be drawn away from the fire.

If another frog is now taken, and a hypodermic of strychnine and adonidin be injected into his posterior lymph-sac, the symptoms produced by the excito-motor are temporarily much decreased in violence, their more decided action coming on only when the strychnine has been absorbed to such an extent as to overpower the more feeble drug. From the first the sensory side of the nervous system is considerably depressed, and a sensory impulse of a very decided character is required to produce a convulsion. Pricking with a pin in any portion of the body fails to cause even a limited spasm, and finally burning of the foot does not cause any explosion of motor impulse. A very beautiful example of the escape of the auditory nerve during otherwise total sensory paralysis from this drug was demonstrated in this experiment.

While no amount of pricking and burning sent a sufficient sensory impulse to the centres in the cord to excite the motor centres, the scratching of a parlor-match, or a sharp blow with the knuckle on a tin can near by, invariably caused a convulsion. Other frogs being taken, their hind legs were severed from their bodies in such a way that the sciatic nerves were the only fibres which bound the legs to the trunk. Adonidin was now injected into one leg below the section, and strychnine was given hypodermically into the lymph-sac on the back. In a few moments a strychnic con-

vulsion came on, which affected equally both legs, showing that the motor nerve-trunks are not affected by adonidin. This experiment also showed that the drug under consideration does not affect the muscles themselves, and galvanization of the muscles failed to show any decrease in their irritability. Galvanization of the sciatic in the poisoned leg failed to show any paresis of that nerve, since it conveyed the impulse to the cord and produced a strychnic spasm. That the peripheral filaments of the sensory nervous apparatus remain unaffected during the poisoning is shown by the fact that, when the tips of the toes of the hind leg which had been poisoned and separated from the trunk, but for the sciatic, are stimulated, the impulse is carried to the spinal centres.

In regard to the practical use of this remedy, one word must be said before closing.

Only one observer, out of many, has reported disadvantageous results from its use, namely, Lublinski, who found that in his cases the drug produced vomiting and diarrhoea. These untoward symptoms must have been due to some mistake in the size of the dose, for in a patient of Durand, who took by mistake 3 grs. of the glucoside, the same symptoms appeared. Perfect recovery was soon reached in this case, although the boy was only 14 years of age.

Durand and others all declare that adonidin is possessed of far greater diuretic properties than is digitalis. Thus, we find that Traversa (*loc. cit.*) says, "It increases the quantity of urine passed from 300 to 400 cubic centimetres per diem to 2000 or 3000, the spec. grav. being diminished, also the total diurnal quantities of chlorides and urea." Œdema is rapidly diminished under its influence. While Durand does not believe that its cardiac effects are equal to those of digitalis, he concludes that in some cases this drug is superior to the latter remedy, particularly where a long-continued course of the glucoside is necessary, since no one has yet found it to be cumulative in its action.

The same writer thinks that convallaria and caffeine possess higher diuretic powers and less cardiac influence than adonidin.

Finally, he sums up the results of his observations as follows:

In doses of  $\frac{1}{2}$  gr. adonidin—

1. Increases arterial tension.
2. Regulates the heart-beat.
3. Diminishes the frequency of the pulse.
4. Increases the force of the cardiac contractions.

5. Acts with rapidity, its effects being only present during its administration.
6. Increases diuresis.
7. Is well tolerated.
8. That the indications for its use are the same as digitalis.

He commends its use, especially in mitral insufficiency and interstitial myocarditis, and in palpitation of the heart. Such a drug ought surely to be of signal service to the profession, for, though it is at present of high price, being made almost entirely by Merck of Darmstadt, there is no reason why a continued call for it should not make its cost within the reach of every one, the *adonis vernalis* being by no means rare, its rhizome having been used as an adulterant for black hellebore, and the process of obtaining the glucoside is not expensive.\*

**Conclusions.**—Adonidin in all doses increases arterial pressure by stimulating the vaso-motor centres and by increasing the cardiac force.

In moderate doses it increases the pulse-rate and force from the first, but when large toxic doses are given, it primarily slows the heart by stimulating the pneumogastric, and then increases pulse-rate by depressing the inhibitory nerves and stimulating the accelerator apparatus.

The slowing of pulse-rate is also in all probability due in part to increased arterial pressure, as under these circumstances the blood-paths are greatly diminished in calibre.

On the nervous system the drug has but little action, unless the quantity administered be enormous. Under these conditions it paralyzes the sensory side of the cord, but has no effect on the motor tract or on the efferent or afferent nerve-trunks.

#### A NEW REMEDY IN CYSTITIS AND LITHIASIS—PICHI (*FABIANA IMBRICATA*).

BY HAL. C. WYMAN, M.D.†

SO short a time has elapsed since this remedy was offered to the medical profession that a report on its use may seem premature. But so long as the report is confined to a simple statement of facts, leaving the reader to judge of the influence the medicine may have had in bringing about the results, no one need scruple at the evidence.

The first case in which I used the fl. ext. pichi was early in January, when my attention

was called to the drug by Dr. J. E. Clerk, the chemist of this city. A Mr. G., aged 23 years, who contracted gonorrhœa a year or more ago, and who had stricture of the urethra, which I found necessary to divulse a few days before Christmas. A copious hemorrhage from the deep urethra followed the operation, and a few days later severe vesical tenesmus disturbed the patient so that sleep and appetite vanished. All the symptoms of typical cystitis speedily developed. Morphine, belladonna, hyoscyamus, and alkalies were used internally and by the rectum for a week without materially modifying the symptoms. So irritable did the bladder become that it would not retain urine longer than five to fifteen minutes. I now began the use of the fluid extract of pichi in 15-drop doses in water once in three hours. The tenesmus and pain began to decline after twenty-four hours, the mucus and pus also to diminish in quantity, and at the end of the week the bladder would retain its contents three hours without causing the patient any inconvenience.

This patient has now, March 8, fully recovered. I think the cystitis was of traumatic origin,—the harsh manipulation of the vesical mucous membrane with the divulsing apparatus. Thompson's instrument was the one used.

Mrs. F., aged 21 years, miscarried two years ago. Since then had not been well enough to do her work. She had backache, dyscinesia, leucorrhœa, rectal and vesical tenesmus. The uterus was lacerated to the depth of one-eighth of an inch on the left side of the cervix. There was marked ectropion of the lining of the cervix uteri. I thought a plastic operation closing the fissure in the cervix would cure her, and I put her under chloroform and operated in December last. She improved for a couple of weeks after the operation in all her symptoms except the vesical tenesmus; this remained the same, and gradually became worse, so that I was obliged to make another study of her case during the last week in January. The urine contained mucus and pus, was alkaline in reaction, and precipitated the phosphates in such quantities that the latter part of the stream in urinating was white as milk. She had exhibited an idiosyncrasy against the use of opiates before I subjected her to the operation for lacerated cervix, so that I did not attempt to get the virtues of those drugs, but put her at once on 15-drop doses of the fluid extract of pichi combined with 1 drachm of simple elixir. Her bladder I washed out daily

\* The Pharmacist, December, 1885, p. 376.

† Surgeon West End Dispensary, Detroit, Michigan.

with a one per cent. solution of cocaine muriate, which controlled the pain admirably. The urine speedily exhibited the odor of the pichi, became acid in reaction, and held the phosphates in solution. She has made a good recovery in the place of what threatened serious progressive invalidism.

Mr. B., aged 25 years, who had been afflicted with cystitis in former years, but had not suffered any symptoms of that disease for more than a year, came under my care at Harper Hospital for the cure of fissure in ano. Under chloroform I paralyzed the sphincter by stretching it with my thumbs. While he was under the influence of the anæsthetic I explored his urethra with a No. 12 (American) sound, meeting with no resistance or impediment to the easy passage of the instrument into the bladder. Two days after this very gentle manipulation of the urinary tract (for I don't think the operation on the sphincter could have caused it) he began to pass turbid urine and to have vesical tenesmus. One-grain opium suppositories had in the mean time been used in the rectum three times a day, easing his pain but not changing the character of his urine. Pichi was now resorted to, and all symptoms of cystitis soon disappeared. At date he continues in hospital, resting for the cure of his anal fissure.

Mrs. —, aged 27, had chronic cystitis, due to neglected retention of urine, following accouchement. She had overflow before the catheter was used to relieve her. I found it necessary to divulse her urethra to insure thorough evacuation of her bladder. It was very irritable after the operation. Pichi combined with fluid ext. hyoscyamus controlled the painful symptoms and gave the bladder the physiological rest essential to a cure.

Mr. H., aged 71 years, had been getting up nights to pass urine for the last five years. Ten months ago he found he could not empty his bladder, and was compelled to call a surgeon to use the catheter. A severe chill followed, and he was very sick for two months, having the catheter used every day. He learned to use it himself, and continued to use it daily until last February, when he had another chill, and his left testicle swelled and inflamed. He was too sick to use the instrument. I was summoned by his medical attendant in consultation, and opened a large abscess of the left testicle, and advised against further use of the catheter. His prostate was greatly enlarged. Opium and camphor suppositories relaxed the spasm of the prostatic muscles so that he got along without the catheter. His

urine was heavily loaded with urates. Mucus, blood, and pus were present in abundance. He was put on fluid ext. pichi, and continued its use for three weeks. He has made an excellent recovery.

I might enumerate numbers of cases of lumbago and sciatica in the course of which urates were precipitated from the urine in large quantities, and which recovered while the patient was taking the pichi. Combined with a potassium salt I have found it to act more quickly than any other remedy in bringing about a solution of the urates and relieving the rheumatic neuralgia so frequently associated with that unstable condition known as lithuria, phosphatism, etc. A formula I have often used is,—

R Fl. ext. pichi, ʒi;  
Potass. nitrate, ʒi;  
Simple elixir, ʒiii. M.

S.—Teaspoonful once in two hours.

#### ARSENIC IN THE TREATMENT OF ARTHRITIS DEFORMANS.

BY KARL VON RUCK, M.D., NORWALK, OHIO.

HAVING met with indifferent success in the treatment of this affection by iodide of potassium and external applications of iodine, and having a patient who, after trying these remedies for some three months, was insisting upon further trial of "no matter what," I determined to resort to arsenic. The patient was a lady, 46 years of age, had passed the climacteric period, and had always enjoyed good health previous to the present difficulty, which had its beginning two years ago, and soon after nursing a near relative during a tedious and fatal illness. She attributed the difficulty to the wringing of clothes out of very hot water while doing this nursing, and so wrenching her finger-joints,—work to which she had not been accustomed. When she came under my care the third phalangeal joints of the fingers, and these alone, were affected in both hands, and the enlargement was very considerable. There was neither pain nor tenderness on pressure, but occasionally what she called rheumatic pains in the affected joints and in the forearm. During the three months whilst I treated her with iodide of potassium the enlargement and the distortion of the affected joints increased, and the second phalangeal joints of the second and third fingers in one, and of the third finger in the other hand, became markedly enlarged, and the

muscles of these fingers showed beginning atrophy. There was also an enlargement of the joint in one of the great toes, which made its appearance during the iodide of potassium treatment.

She was now put upon Fowler's solution, 4 minims after each meal, and after two months' steady treatment, although no improvement could be made out, she had not grown worse, and this was deemed of sufficient encouragement to continue the remedy in somewhat increased doses.

When, at the end of two more months, the patient presented herself again, a slight improvement in the enlargement of the third phalangeal joints, especially of one hand, was thought to be noticeable, and the patient herself felt well convinced thereof, so she was advised to continue the treatment, with occasional intermissions, as the arsenic had upon several occasions produced a little puffiness of the lower eyelids. I did not see her again until over a year later, when she brought me another patient of the same class, at the same time showing me her hands, upon which no trace of the arthritic process could be discovered. She had taken the arsenic for six months longer, and then discontinued it, having only a very slight enlargement left in two or three joints, which disappeared afterwards without treatment. The toe, she said, had also got well.

This second patient had been under the care of many doctors, and her case dated back some six years; but she had never taken arsenic. No cause was assigned by her. She had had rather poor health for many years, suffering from dyspeptic troubles, and her present deformity made her very miserable, on account of the restricted use of her hands, and particularly on account of their unsightly appearance. She had just returned from a visit to the Hot Springs of Arkansas, and said that she had grown much worse under the treatment there.

Without going into further details of this case, I will simply say that she was put upon arsenic, and that although not entirely cured the patient has been greatly benefited in the course of a year. She is able to use her hands almost as well as she ever could, and her general health has been much improved, owing to the simultaneous relief of her dyspepsia. The articular enlargements are certainly diminished by one-half, and the contractures are yielding to a steady course of massage and manipulation. She is still under treatment.

In connection with these cases I would like to call attention to the etiological factor in arthritis deformans, especially in the first case; here the theory of a central cause situated in the nervous system finds good support. The development of the disease after nursing, and the death of a near and very dear relative, with the attending anxiety and grief, the symmetrical development and progress of the case, the trophic disturbances, all point in that direction; and I believe this theory to be further confirmed by the results obtained from arsenic, which, in my opinion, produces its therapeutic effects always by its action upon the nerves and nerve-centres.

*THE PHYSIOLOGICAL ACTION OF USTILAGO MAIDIS ON THE NERVOUS SYSTEM.*

---

BY JAMES MITCHELL, M.D., LANCASTER, PA.

THE knowledge which we possess of the *ustilago maidis* is so very meagre that I have not been able to find any detailed account of its physiological action. It formerly received a brief notice from the German profession, but has never excited much interest until within recent date. By the above profession it is stated to possess abortifacient powers. We find mention made of the drug in Dr. H. C. Wood's *Therapeutics* for 1880 under the head of oxytocics, where it is stated "to appear to have active medicinal properties, and to have been used successfully in uterine inertia during labor by Dujardin-Beaumetz." Its more extended use of late seems to me to warrant a close study of its physiological action. Therefore, in accordance with the title of this paper, I have endeavored to ascertain, by means of an experimental research made in the Physiological Laboratory of the University of Pennsylvania, what action, if any, the drug possessed upon the nervous system. The animals used in my experiments were frogs. The plan which I pursued was to consider first the general action of the drug, and then any special action it might have upon the nervous system.

*General Action.*—The first effect witnessed after the injection of ten or fifteen minims of the fluid extract into the posterior lymph-sac of normal frogs was profound narcosis. The batrachian appeared greatly depressed, and

would remain motionless. The respiratory movements as a rule became rapid and irregular, at other times they were almost imperceptible. During the first stage of the poisoning voluntary movement was maintained. A semi-comatose condition, which was so marked in the early stage of the poisoning, was often succeeded by a short period of excitement, during which the batrachian would make frequent changes of position. This was quickly followed by great diminution of voluntary movement, succeeded by muscular tremors and clonic spasms. The muscular irritability appeared to be greatly increased. All the above symptoms then terminated in paralysis. At one stage of the poisoning anæsthesia of the surface became marked, and the animal would submit to pinching or burning without moving, though it was evident that the power of voluntary movement was not lost, from the fact of its occurring after the removal of the stimuli. If the dose was insufficient to produce death, all the above symptoms abated, the paralysis disappeared, and in the course of from one to two hours the animal appeared to have regained its normal condition. After one of my experiments the frog was observed for five days, and appeared during that time perfectly normal, proving, I think, the temporary effect of the drug.

With full toxic doses (20 to 25 minims) the above symptoms were greatly intensified. Coma and stupor were marked. The respiratory movements became very irregular. Great muscular weakness and relaxation followed, after which the muscular tremors, and, in the majority of cases, the clonic spasms, ensued, followed by paralysis and death. The pupils were contracted. The cutaneous anæsthesia was developed very early in the poisoning.

The immediate cause of death is, I think, due to a paralytic arrest of the respiration, since I found that the heart was beating rhythmically after all external signs of life had ceased. It has also continued to beat for one hour after the thorax was opened. The only exceptions to the above statement were noticed in two of my experiments, where the heart was found arrested in diastole. In one experiment it began beating feebly when mechanically stimulated, while in another experiment the auricles would contract, but not the ventricles. I also noticed that when five or six drops of the fluid extract were placed upon the exposed heart its movement would be arrested for a moment,

though it quickly began beating again with slower rhythm. The coma and stupor, with the marked anæsthesia of the skin, would indicate that the drug possesses certain narcotic or analgesic principles. It is also evident that the action of the drug is essentially of a paralytic nature, the paralysis in all cases being much more marked than the spasms. With very large doses of 30 minims the animal sank down almost immediately paralyzed, with only a few muscular twitchings. All voluntary movement and reflex action were abolished. The pupils contracted, and in a very short time the irregular respiratory movements ceased. Death in these cases also appeared to be due to failure of the respiration, since the heart was found beating.

*Special Action.*—It is evident, I think, from the above results, that the most characteristic effect of the drug is one of paralysis. The question, therefore, naturally arises, To what is this paralysis due? To ascertain this I made three sets of experiments upon reflex action, in all of which experiments the frog was pithed, so as to eliminate voluntary movement, and, at the same time, any action of the drug upon the hypothetical inhibitory centres of Setschenow in the medulla oblongata.

In my first series of experiments upon reflex action I observed that it was slowly and gradually diminished with small doses, until a period was reached when it suddenly ceased. The time required to produce this effect varied, and was also dependent upon the size of the dose. With large doses—of 25 or 30 minims—reflex action was abolished in from six to eight minutes; while small doses—of from 10 to 15 minims—required from thirty minutes to one hour and thirty minutes.

A brief description of the manner in which my experiments were conducted will, I think, be of value. The frog was first pithed, and allowed to remain in a dish of water until the shock of the operation had passed off. It was then suspended carefully by a wire through the lower jaw, and reflex action tested at regular intervals by immersing the posterior extremities in a two per cent. solution of sulphuric acid; the time from the contact of the toes with the dilute acid and a contraction of the limb being carefully noted, since this would indicate a normal reflex. After each test the frog's legs were carefully washed of the acid solution by a gentle stream of water, so that the sensory nerves of the skin might not be affected by the prolonged local action of the acid.

Two experiments were made expressly with large doses of the fluid extract of *ustilago maidis*, so that it might be proven conclusively that the diminution and final abolition of all reflex phenomena were due to the direct action of the drug, and not to any local action of the dilute acid upon the skin. And that this is the case is, I think, proven from the fact that, though reflex action was strong before giving the poison, after giving these large toxic doses it was abolished in from six to eight minutes.

The fact that *ustilago maidis* diminishes and finally abolishes all reflex action is abundantly proven, I think, by my experiments, the details of which I omit for lack of space. The question therefore arises, To what is this loss of reflex activity due? It is evident that the suspension of reflex action can only be produced in three ways,—by paralysis of the spinal cord, of the nerve-trunks or peripheries, or of the muscles, or to two or more of these causes combined. I will, therefore, consider the action of the drug upon these parts of the system in inverse order.

That the loss of reflex activity is not due to a paralysis of the muscular system is clearly shown in the second series of experiments which were made upon reflex action. I have observed in them that long after the strongest secondary current from a single-gravity cell and a DuBois Reymond's induction coil had failed to elicit the slightest reflex movement, when a mixed nerve (sciatic) was stimulated, the tributary muscles contracted strongly; and later, when the efferent nerve had failed to conduct the impulses to the muscles, strong contractions could still be induced by the direct application of the electrodes to the muscle. This clearly proves that the muscular irritability was still maintained.

Since reflex paralysis, which was so marked in the former experiments, is not due to a paralysis of the muscles, it must be due to a paralysis of some part of the nervous apparatus.

That the loss of reflex action is not due to a paresis of the motor nerves or peripheries is evident from what has been said in the paragraph before the last. Furthermore, other experiments clearly prove the above statement. For I have seen that though the direct stimulation of a mixed nerve (sciatic) with the induced current would produce violent contractions in its tributary muscles, not the slightest reflex tremor could be induced. That the motor nerves are, however, ultimately depressed, and finally paralyzed,

has also been ascertained by using definite strengths of the electrical current; it having been found that to produce these muscular contractions a gradual increase in the strength of the current was necessary, and that very late in the poisoning the strongest current failed to elicit the slightest response, though the muscles would still contract when directly stimulated. The experiments from which the above conclusions were derived were conducted in the following manner: The frog was first pithed and the left sciatic nerve exposed. The animal was then allowed to remain in water until the shock had passed off; after which the nerve was stimulated by an interrupted current obtained from a gravity cell and a DuBois Reymond induction-coil. The number of centimetres the secondary coil was removed from the primary in order to obtain just sufficient strength of current to produce a reflex movement was then carefully noted. The drug was then injected into the posterior lymph-sac, and the above test again repeated at intervals of ten minutes or more, the nerve being always stimulated at the same point.

Since it is abundantly proven that reflex paralysis is produced before the motor nerve-fibres and the muscles have lost their irritability, the question arises, whether the paralysis be spinal or due to a paralysis of the sensory nerves? That the loss of reflex action is not due to a primary paralysis of the afferent nerves seems indicated by the fact that if all the blood-vessels going to the posterior extremity of a frog were ligated, so as to prevent all access of poison to the limb, reflex action would be abolished in the protected limb *pari passu* with the unprotected leg; indicating, I think, that the failure of reflex movements in the unpoisoned limb must have been due to the direct action of the drug upon the cord. Further, by applying the interrupted faradic current to the exposed spinal cord in the dorsal region of poisoned animals strong contractions were induced in the posterior extremities, while no movements were produced in the anterior extremities, certainly showing that the failure of the cord to convey impulses upwards must have been due to a paralysis of its sensory (receptive) portion, while the motor portion must have been still capable of conducting impulses, as was evident by the contractions of the posterior extremities. That the motor portion of the cord is ultimately depressed is also indicated by the fact that the electrical current has to be gradually increased to cause these muscu-

lar contractions. It is obvious, therefore, that the seat of reflex paralysis lies in the sensory (receptive) portion of the cord. I would, therefore, conclude from my experiments on reflex action, that the *ustilago maidis* diminishes and finally abolishes all reflex movement by a paralysis of the sensory (receptive) portion of the cord; also that the motor portion of the cord and the motor nerves are ultimately depressed, as ascertained by definite strengths of the electrical current.

Whether the peripheries of the sensory nerves are affected or not early in the poisoning I have not been able to decide, on account of the early depression of the sensory portion of the cord.

The experiments from which the above conclusions were derived were made as follows: The frog was first pithed, and all the tissues of the left posterior leg, except the nerve, were then ligated, so that all access of the poison to the limb might be prevented. The frog was then allowed to recover from the shock; after which reflex action was tested by immersing the posterior extremities in a two per cent. solution of sulphuric acid. The frog's legs were carefully washed of the acid solution by a gentle stream of water after each test. After reflex action had ceased, the cord was exposed in the dorsal region, and stimulated directly by the electric current from a single-gravity cell and DuBois Reymond induction-coil.

The course of the paralysis having been ascertained from the preceding experiments, the question presents itself: To what are the convulsions, which were noticed in the above experiments, due? I may here add that my results have not been at all conclusive upon this subject, owing partly to the fact that at this time of the year (November) the frogs are in poor condition, and also to the fact that the paralytic phenomena were at all times predominant. That the convulsions are not of cerebral origin is proven by direct experiment, they having been observed in pithed as well as in normal frogs. It was also observed that they occurred in the posterior extremities after the cord was bisected in the dorsal region. Whether they are of spinal or muscular origin I have not been able to decide from the experiments which I have made. I have, however, seen that in experiments where the nervous connection only was maintained in the left posterior limb no movements whatever occurred in that limb when they were occurring in the other parts of the body, while in another experiment, under precisely similar

circumstances, active movement occurred in the protected limb. In other experiments, when the nervous connection of the limb was severed, precisely opposite results again occurred. That the drug may act primarily as an irritant to the muscular and nervous tissues seems probable.

The conclusions at which I arrived from my experiments are, that the ultimate action of the *ustilago maidis* upon the nervous system is that of a universal depressant, producing a diminution and final extinction of all reflex and volitional phenomena, with the early induction of narcotism. That the loss of reflex activity is due to the paralysis of the sensory (receptive) portion of the cord. That the motor portion of the cord is also depressed, as well as the motor nerves. That it is also probable that the sensory nerves share in the general paralysis.

That death is due to arrest of respiration, though in exceptional cases it may be due to the diastolic arrest of the heart.

The marked similarity between the action of this drug and that of potassium bromide is worthy of note, although in my experiments I have never observed voluntary movements occur after the suppression of reflex activity, which are so commonly observed in poisoning with the potassium bromide. Though the possibility of such movements is evident, from the fact that the motor portions of the cord and the efferent nerves remain sufficiently intact in the early stages of the poisoning to convey impulses after the complete paralysis of the sensory portion of the cord. That voluntary movements, or, at least, movements the impulses of which have their origin in the cerebral ganglia may occur, is readily conceivable. The fact that they do not occur is conclusive proof, I think, that the cerebral ganglia are early depressed in the poisoning, and finally paralyzed. This is further shown in the profound narcosis seen almost immediately after giving the poison.

In the early part of this paper it was stated that the *ustilago maidis* was classed with the oxytocics, and it has also been asserted to possess medicinal properties resembling those of ergot of rye. Without further discussion I will place in parallel columns a summary of the conclusions drawn from the results of the present research, with those conclusions arrived at by the different investigators on the action of ergot of rye and that of potassium bromide, which it so closely resembles in its physiological action on the nervous system.

## USTILAGO MAIDIS.

Nervous system: Cerebrum consciousness in frogs lost.

Spinal cord: The sensory portion of the spinal cord is first paralyzed, the reflex paralysis being due to this cause. The motor portion of the cord, as well as the motor nerves, are also depressed, and ultimately paralyzed. That it is also probable that the sensory nerves share in the general paralysis.

## POTASSIUM BROMIDE.

Cerebrum, spinal cord, and nerves: "The evidence is, I think, sufficient to prove that bromide of potassium affects all parts of the nervous system of the lower animals, but that the cerebrum, the motor tract of the cord, and the efferent nerves are the last portions to be affected; that the most sensitive to its action is the receptive portion of the cord, and next to this the peripheral ends of the afferent nerves." (H. C. Wood's Therapeutics, 1880, p. 325.)

## ERGOT OF RYE.

"The above summary of the general symptoms caused by poisonous doses of ergot shows that the phenomena are mainly paralytic in nature." "It would seem that the nervous system must bear the brunt of the poison." "It is probable that the chief action of the drug is upon the nerve-centres." (H. C. Wood's Therapeutics, 1880, p. 543.)

## RED SULPHUR SPRINGS, MONROE COUNTY, W. VA.

BY L. B. ANDERSON, M.D., NORFOLK, VA.

THOUGH I have been acquainted with the medicinal virtues of these waters for many years, I have visited the Springs only once, and then for a very brief period. I am now unacquainted with the owner or proprietor, and know not what are the facilities provided for reaching them, or for the accommodation of guests. When I visited them, some five years ago, I embarked on an ambulance drawn by two horses, in company with four passengers, at Lowell Station, Chesapeake and Ohio Railroad. The route was mountainous, picturesque, and fascinating. Emerging from a forest on a high mountain, we caught the first view of the Springs in a valley a mile or more to the south of us, and sweeping rapidly down the declivity, we were soon landed at the office of the spacious hotel on the eastern side of the valley.

The grounds occupy a valley running north and south, not over a hundred yards wide and a few hundred yards long. It is bounded on the east by a mountain, rising at an angle of say  $40^\circ$ , on the base of which are located the most commodious buildings. On the west rises another mountain, at an angle of  $67^\circ$ , high into the air, at the base of which sweeps a small creek, which affords fine facilities for sewerage. Bordering on that stream is the long western range of buildings, at the southern extremity of which are the springs, two in number, and slightly different in their composition. They are very neatly and substantially walled, and present a very attractive and enticing appearance. Standing in the long portico of the eastern hotel and looking westward, just in front stands the long row of western buildings, behind which rises the steep and lofty mountain, covered with trees

and rich foliage. To the left are the springs very near by, and a hundred or two yards to the right is the abrupt termination of the western mountain, around which sweeps the valley creek to empty into quite a bold stream coming down the valley from the right and north, to hide itself behind the western mountain.

The accommodations, when I was there, were very satisfactory. Beef, bacon, fowls, milk, and butter of the very best quality were abundant, and vegetables of all kinds plentiful. The water is perfectly clear, sparkling with disengaging gases, and very cold. Though it is quite strong in sulphurous and saline taste, it is not as offensive as most other mineral waters, and, after their use for a day or two, no other water is desired. Most persons experience a peculiar exhilaration after drinking a free potation, somewhat akin to champagne. We are now prepared to enter into an analysis and examination of their medicinal qualities.

Many years ago Dr. William Burke, of this State, who resided at the Red Sulphur Springs, wrote the fullest account of what was then known of their qualities that I have ever seen. An analysis of the waters, which, though probably as accurate as the state of chemical knowledge at that period could secure, was evidently very imperfect, is given in his essay. The first is from Prof. Rogers, and is as follows:

"Gaseous contents in an imperial gallon:

Sulphuretted hydrogen .....	4.54
Carbonic acid .....	8.75
Nitrogen.....	4.25

Solid contents consisted of sulphate of sodium, lime and magnesia, carbonate of lime, and muriate of sodium. Besides these ingredients, the water contains, in considerable quantity, a peculiar organic substance, which, mingled with sulphur, is deposited on the sides of the spring, and seems to increase by a species of organic growth."

The next analysis was furnished by Dr. Hays, of Roxbury, Mass., and is, in brief, as follows :

"Fifty thousand grains, or about seven pints, of the water, when evaporated, left a solid residuum of 20.56 grains of a light yellowish matter, which, when subjected to a still higher temperature, was reduced to 17.55 grains. This residue contained

Silicious earthy matter, with traces of iron and alum .....	0.70
Sulphate of sodium .....	3.55
Sulphate of lime.....	4.50
Carbonate of magnesium.....	4.13
Sulphur combined with organic matter.....	7.20

This last peculiar sulphur compound has never been described, if, indeed, it has ever been met with. Out of contact with air it forms a permanent solution. In its decomposition ammonia is formed, and hydro-sulphuric acid is liberated ; if heat be employed, sulphur is liberated. The gaseous constituents are,—

Carbonic acid .....	5.750
Nitrogen .....	6.916
Oxygen.....	1.201
Hydro-sulphuric acid gas.....	.397."

Dr. Burke gives the testimony of many who had tested the virtues of these waters on themselves and their patients, from which we extract the following :

"Dr. Scott, a distinguished physician of Kentucky, says, 'For three months my pulse had not been less than 100 strokes per minute in the morning and 110 in the afternoon. In three days after beginning the use of the water it was reduced to 70 in the morning and 80 in the evening, etc.'

"Dr. Henry Hunt, of Washington City, says, 'I was attacked with a slight hemorrhage from the lungs, attended with other symptoms, indicating a diseased state of those organs. On the evening of my arrival at the Springs I commenced the use of the water. I had evening exacerbations of fever, pulse 115, and night-sweats. In ten days my pulse was reduced to 78 in a minute. I could, by increasing or diminishing the quantity of water, act at will on my kidneys or bowels. It exerted the most soothing and soporific effect, and often gave quiet rest when potent anodynes had failed. I felt the good effects for months after leaving the Springs.'

"Dr. R. H. Bradford, of Virginia, says, 'The effect of this water in reducing the pulse is one of the numerous singular and powerful properties belonging to it. It lessens

arterial action to such a degree that it seldom fails to remove fever, pain in the chest, and difficult breathing. It may be taken with greater advantage in pulmonary troubles than any other remedy I have ever seen used for them.'"

Cases are given in which bronchial and laryngeal troubles of grave character were entirely relieved, while severe cases of tubercular pulmonary infiltrations and abscess were greatly modified in their character and stayed in their progress.

My own observations of the remedial powers of the Red Sulphur waters began with a young man who had grown to the height of six feet five inches in nineteen years, whose physical force was so feeble that he scarcely developed vitality above that of a delicate vegetative existence. His lungs were weak, his muscles were slender and relaxed, his digestive powers were feeble, his pulse was frequent, and he presented all the more striking indications of incipient phthisis. He visited these Springs, and remained six months, during which time there was an entire renovation in his physical constitution, and his mental as well. From a spindling, emaciated, feeble, overgrown youth he became a robust, muscular, and vigorous man, weighing more than two hundred pounds, which weight he has retained through all the years of a college curriculum, and other draughts upon him, till this time, now many years.

I have prescribed these waters to patients laboring under advanced phthisis pulmonalis with decided comfort, and frequently a great modification of their most distressing symptoms, and that, too, when the water was used from bottles which were transported hundreds of miles.

While at the Springs I saw an intelligent lawyer from North Carolina, who informed me that five years before he had been so reduced by a harassing pulmonary trouble, attended with decided hectic, that he was compelled to relinquish his practice. He came to the Springs in such a feeble state that he feared he would not survive the trip. But he was so much benefited that he was enabled during the following winter to resume the lighter duties of his profession. He had made annual pilgrimages to the Springs, and at the time I saw him he had just paid his fifth visit. With each annual visit there was a marked improvement in all his symptoms, and he was then able to perform all the work needful, both in office and at the bar, to meet the requirements of an arduous calling. I

met there with a distinguished minister of the gospel who had a laryngeal trouble of such a character as to incapacitate him for public speaking. He had not used the waters more than ten days before he was entirely restored. I saw children who were brought there in an advanced and emaciated state of cholera infantum, who were said to have improved in twenty-four hours after reaching the Springs.

It is to be regretted that no recent analysis of the water has been made. Some one has conjectured that the "yellow, undefinable mass," which is formed by precipitation on exposing the waters to the influence of the air, contains iodine, on what ground I know not. But there seemed to be a settled conviction in the minds of those who had the best opportunities for knowing, that such is the case. Whatever be the constituents of these waters, there can be no question of their wonderful sanative powers in affections of the throat, larynx, trachea, bronchia, incipient tuberculosis of the lungs, and all the mucous tissues extending into the stomach, bowels, liver, kidneys, bladder, and uterus. Much of the benefit which they exert results no doubt from the promotion of the secretions, as Dr. Hunt informs us, from the liver, kidneys, and bowels. So soon as his liver and kidneys were brought into vigorous and healthful exercise, and the bowels were freely acted on, his pulse became slower and steadier, and all his symptoms were greatly improved. But one peculiar effect of the waters—that is, its soothing and soporific influence—cannot be accounted for by any known constituent; and yet there can be no question that this peculiar property is wonderfully promotive of its sanative effects. One of the chief sources of irritation in all chronic pulmonary troubles is the agitation of the inflamed tissues from frequent paroxysms of coughing. Another is the prolonged wakefulness produced by this source of trouble. The great difficulty which confronts the medical man in meeting these troublesome issues is, that such agents as are at his command, which are calculated to exert a soothing and soporific effect, are constipating and astringent, or debilitating to the digestive organs. In this water we have an agent which not only quiets the cough and soothes the local irritation, but produces sleep, promotes the secretions, and gives tone and energy to the digestive organs, upon the activity and integrity of which so much depends the reparative process. From this stand-point alone these waters are worthy of all commendation.

While I was at these Springs I was struck

with the entire want of system manifested by those who were using the waters and mostly needed their potential effects. No doubt many used the waters most injudiciously, and hence failed to receive a moiety of the benefit they might otherwise have derived. And yet there were numbers there who, despite their indiscriminate use, were loud in their praises of their curative powers, and even resolved to make annual pilgrimages to these Springs. My own convictions are, that among all the valuable mineral springs of which the Virginias can boast, the Red Sulphur does and must ever stand pre-eminent. And for scorbutic troubles, whether in the glands, lungs, throat, or eyes, I believe that these waters are without an equal on the globe.

#### COCAINE AS AN ANÆSTHETIC IN CIRCUMCISION.

BY JOHN MADDEN, M.D., ASHLAND, WIS.

ON February 2 I circumcised a young man, æt. 28 years, possessing a very nervous temperament, using a four per cent. solution of the muriate of cocaine as an anæsthetic.

Four points, practically equidistant, were selected upon the line of the intended incision, the hypodermic needle inserted, and about one-fourth of a drachm of the solution was injected beneath the skin at each of these points. A piece of absorbent cotton was then saturated with the fluid, and placed in contact with the preputial mucous membrane.

Testing the sensibility of the parts from time to time, by pricking with a needle, in about twenty minutes the sense of feeling was almost entirely abolished. The foreskin was then drawn forward, held between the blades of a pair of dressing forceps, and quickly ablated with a knife. The patient declared that the operation gave him no pain nor sensation of any kind, excepting in one small place on the left side. I noticed, however, that the solution had filled the subcutaneous tissue beneath this place. The mucous membrane was next caught up, and quickly cut off with a pair of scissors. Its sensibility, though very much lessened, was not entirely destroyed, and the patient complained of some pain. The operation was completed by stitching the mucous membrane and integument together, the former growing more painful towards the end of the operation, while the latter preserved its anæsthesia.

No constitutional symptoms were observed from the absorption of the cocaine.

*TAPEWORM ACCIDENTALLY REMOVED  
BY CHLOROFORM.*

BY W. H. BENTLEY, M.D., LL.D., WOODSTOCK, KY.

I N September, 1885, I had occasion to visit a friend in an adjoining county on non-professional business. As his wife was in ill health, he wrote me a request to bring some medicine. Accordingly, I took along my usual travelling outfit of drugs. At 10.30 P.M. one of my friend's tenants sent his son in great haste to request my immediate attendance. The young man stated that his mother had had chills for several weeks, that a physician had seen the case several times, had "stopped" the chills each time, but they had returned again. Lately, however, she had been using Ayer's ague cure. This, he said, was the first chill during two weeks, and that it had already lasted between two and three hours.

I hastened to the patient to find her gasping for breath, radial and temporal pulse imperceptible. Surface and extremities cold, and the entire person bathed in a profuse clammy sweat. There was evidently no time to be lost, so, calling for some sweet milk, I at once administered a drachm of chloroform in about an ounce of milk.

The patient began to rally almost immediately, and at the end of forty minutes from the ingestion of the chloroform the circulation appeared normal. I have often administered chloroform during the cold stage in intermittent fever, and I have never known any marked degree of fever to supervene, and this case was no exception to the rule.

At half-past eleven o'clock, a little over one hour from the administration of the chloroform, I gave her 2 grs. podophyllin, 5 grs. bicarb. sodium, and 10 grs. quinine sulph. in half a wineglass of water, directing an ounce of castor oil, with half ounce spts. turpentine, to be given on arising in the morning. The excitement and worry of the occasion kept the family awake so late that they did not arise until the sun was an hour or two high, so the oil and turpentine were not given until 8 A.M. at least. At eleven o'clock I called, preparatory to leaving for home. When I arrived I was told that the patient was "over the vessel." In a short time I was admitted. You may judge of my surprise when I exam-

ined the discharge and found a tapeworm thirty feet long.

This is not the first tapeworm which I have removed by means of chloroform, but it is my first *accidental* removal of one.

Hitherto I always gave the chloroform, and followed directly with a large dose of castor oil and a full dose of croton oil combined, supposing that the chloroform only stupefied the worm, but to my mind the details of this case tend to show that it actually kills the parasite. It was dead when passed, and appears from the statements of the patient to have been in a coil or knot, for she said it gave her intense pain.

Did the chloroform kill the worm, or did the podophyllin and quinine do it? Could it be possible that it died in consequence of the sickness of its hostess?

I once had an inveterate case of typhoid fever, lasting sixty-three days. The subject was a man, 35 years of age, and the case occurred within a few months after I began to practise medicine. When the patient began to recover, his convalescence was at first extremely tardy. After a few days he began to pass sections of tapeworm with his stools. This continued during several days, and then the head came away. The portions were in an advanced state of decay. I was then afraid to give a cathartic to clear the bowels, lest his diarrhoea might return, so I have since found that I left him exposed to real danger by leaving him so long in retention of the putrid mass.

I have often wondered whether in this case the tapeworm died from the effects of the disease, the medicines, or from starvation.

*CHIONANTHUS VIRGINICA.*

BY JOHN A. HENNING, M.D., GARNETT, KANSAS.

THIS is a shrub or small tree growing along creeks or rivers, mostly in the Southern States. Leaves obovate, lower surface downy; flowers, loose panicles in early summer; petals about an inch long, and the fruit blue-purple, with a bloom; common name, *fringe-tree*. The bark of the root is the only part employed. It is made and used in the form of a fluid extract. Dr. Justice has found saponine in it, but the plant has not come into general use.

Having used the fluid extract of *chionanthus* extensively in my practice for the last ten years, I can speak from personal experience as to its therapeutic action.

To simply say that a good article of the fluid extract, given in doses of half to one fluidrachm two or three times per day, is an aperient, cholagogue, diuretic, and an alterative, would but imperfectly describe its physiological effect in the human system. Of course, we should and must know its therapeutic effect, but we also must know when and in what pathological condition the system is in before we can prescribe it rationally. Some writers have said heretofore that chionanthus is a specific in jaundice. Although I believe there are no specifics for any disease, my experience warrants me in saying that this remedy is one of the best in jaundice that I have ever prescribed. Chionanthus is indicated in all cases where there is a yellow, jaundiced condition of the skin. While it is but a feeble hepatic stimulant, I think it is one of the most reliable remedies in congestion of the portal circulation that we have. I have seen this verified in a large number of cases. It also seems to stimulate the lymphatic system, and to possess some diaphoretic and diuretic action.

If the liver is torpid, other hepatic stimulants should be used, such as podophyllin or leptandrin. The following prescription is the form in which I use this remedy :

R Ext. fld. chionanthi,  $\mathfrak{z}\text{i}$ ;  
Podophyllum,  $\mathfrak{z}\text{i}$ ;  
Potass. acetat.,  $\mathfrak{z}\text{ss}$ ;  
Aquæ, q. s. ad.  $\mathfrak{z}\text{iv}$ . M.

Sig.—Teaspoonful every three to six hours.

In all jaundice condition this prescription has never failed me. However, other remedies may be indicated, as jaundice is but a symptom, not a disease, and many causes may produce it.

#### THE USE OF NITRITE OF AMYL IN THE SEVERE PAROXYSMS OF WHOOPING-COUGH.

BY DR. MORRIS J. LEWIS, PHILADELPHIA.

**E.** B., female; æt. 13 weeks; breast-fed; a well-formed, healthy baby; rather small, and weighing about nine and one-half pounds.

At the age of seven weeks, having just recovered from the effects of a perfectly normal vaccination, she contracted whooping-cough from her brother, whose case had been one of the lightest character, rendering the diagnosis impossible for over two weeks. The

infant's cough for the first week was but slight; but during the second week it began to show the characteristic symptoms.

The child was placed upon a mixture of belladonna and alum every three hours, and progressed favorably until the night of February 12, towards the end of the second week of the disease; it was then seized with a violent paroxysm of coughing, became purple in the face, and finally, according to the mother's statement, ceased to breathe. I was immediately sent for; but before I could answer the summons the mother had thrust the child out of the window into the cool, damp air of a foggy night. This procedure was immediately followed by an inspiratory effort, and the child breathed again. When I arrived the child was in an exhausted state, but was breathing regularly. After this, until the 22d of the month, but one other slight attack of this nature occurred. By this time the child was coughing in a perfectly typical manner. The medicine was continued, but in slightly larger doses, the child taking about the  $\frac{1}{2}$  gr. of extract of belladonna in the twenty-four hours.

On the night of the 22d there were three severe paroxysms, during all of which I was present.

The child would awaken with a series of violent expiratory coughs, with scarcely an inspiratory effort between them. Finally, an expiratory spasm would occur, lasting fully fifteen seconds, during which the child would struggle and become perfectly livid. This would be succeeded by complete collapse, with entire suspension of respiration, due probably to exhaustion of the respiratory centre.

During the last two of these attacks I administered ether by inhalation, and believe that thereby the spasmodic stage was somewhat shortened, but the subsequent collapse was so severe that I was obliged to resort to artificial respiration, and once had to continue it for ten minutes, as during that time there were but one or two feeble attempts at inspiration. The evening before I had placed the child on the  $\frac{1}{10}$  of a grain of sulphate of atropine every three hours.

Dr. William Pepper then saw the case with me in consultation, and suggested combining a small amount of nitrite of amyl with the ether to prevent if possible the stage of exhaustion. This combination seemed to have a good effect; but, as the amount of ether required seemed to render the child drowsy and disinclined to nurse, I gradually dimin-

ished the proportion of ether until the mixture contained one-fourth part of nitrite of amyl. This mixture was kept in a small vial, and with each cough the end of the finger was wetted with the mixture and held close to the child's nose and mouth, so as to catch the first inspiratory effort. Thus administered, the child practically got nothing but nitrite of amyl. After the commencement of this treatment the child never had another attack of exhaustion, and the severity and length of the paroxysms seemed to be materially lessened, although the child coughed just as frequently, the number averaging fifty in the twenty-four hours, the amyl being given each time.

No untoward effects were at any time noticed, even when once I held the bottle, containing at least 10 drops of amyl, to the child's nose.

It was difficult to judge of the amount of flushing produced by the drug, on account of the flushing caused by the cough.

This treatment was continued for two weeks or more, and during this time the sulphate of atropine was continued in doses averaging the  $\frac{1}{100}$  of a grain every three hours.

I am confident of the beneficial effect of the nitrite of amyl in this case, and, although one swallow does not make a summer, I think the drug will be found of use in analogous cases; the tendency to apoplexies of various kinds, and some of the other complications, being also probably lessened thereby.

Dr. John M. Taylor, who assisted me in watching the case, is also positive of the good effect produced.

In the short time that I have had to look up the literature of the subject, I cannot find that nitrite of amyl has been used in whooping-cough, nor has anybody that I have spoken to on the subject known of its use.

By diluting the nitrite with ether or alcohol it can be administered in any dose required, and could more easily be placed in pearls than the pure nitrite.

By placing it in a bottle with a small top, that can be covered easily by the finger, it can be almost immediately administered by simply wetting the tip of the finger by inverting the bottle.

The child is now doing well, and has had no complication other than a slight umbilical hernia.

1218 WALNUT STREET.

#### YERBA SANTA AS A VEHICLE FOR QUININE.

MR. J. D. A. HARTZ proposes a preparation of yerba santa, in addition to those already on the market, for disguising the taste of quinine (*American Druggist*, March, 1886). One fluidrachm of this preparation is said to obliterate the taste of two grains of quinine.

The first step in preparing it is to exhaust twenty-five ounces of powdered yerba santa (the powdering can be easily accomplished in a drug-mill to a degree of fineness that sifting can be dispensed with) with a menstruum of one volume of alcohol and two volumes of water, regaining the alcohol by distillation, and reducing the remainder over a water-bath to twenty-five fluidounces. In the still, and also in the evaporating dish, will be a copious deposit of resin which seems unessential for the purpose, and is designedly separated, as an alcoholic fluid extract of yerba santa would produce an unsightly mixture.

The next step is the preparation of a syrup by intimately mixing in a mortar three hundred minims of oil of sweet orange with three ounces of finely powdered phosphate of lime, gradually adding three fluidounces of alcohol, and afterwards, also very gradually, eighty-five fluidounces of water. Transfer the mixture to a bottle, add one hundred and fifty minims of purified chloroform, and shake vigorously for half an hour, filter, and dissolve in the filtrate one hundred and forty ounces of sugar, add the fluid extract and enough water to make two hundred fluidounces.

#### POISONING BY VASELINE.

MR. H. S. ROBINSON states in the *British Medical Journal*, February 13, 1886, that he was summoned to see three children aged from 8 to 14 years, who had each been given about half a teaspoonful of vaseline on sugar the previous evening, as they suffered from sore throats. Soon afterwards, whilst in bed, they were all seized with pain in the knees and cramps in the lower extremities, together with severe vomiting, which continued for eight or nine hours. On visiting them the next morning the severity of the symptoms had passed off, although the eldest child was still inclined to vomit, and was in a somewhat collapsed state. There were no febrile symptoms, and they all quickly recovered their usual health. No other cause for these symptoms than the administration of vaseline could be discovered.

### HOPEINE.

THE remarkable discovery was announced about a year ago of a new alkaloid to which are due the narcotic properties generally attributed to hops. To this alkaloid the discoverers—Williamson and Springmuhl, of London, England—gave the un-euphonious name of hopeine, driven to this alternative, it would appear, by the circumstance that the names lupulin and humulin, which the ordinary practice in scientific nomenclature would have suggested, were pre-occupied. In view of the fact that previous investigators had never found in this drug any such alkaloid, the announcement was received with some incredulity, but a ready explanation was forthcoming. The new alkaloid, it was stated, is contained in ordinary cultivated hops only in very minute quantities. In the wild American hop, however, it was said to be present in the proportion of fifteen parts in ten thousand, or about ten grains in a pound. It was stated, however, that in practice the yield was only three or four grains from a pound of the crude material.

The process by which the alkaloid was obtained was totally unlike any recognized process for extracting alkaloids. The hops were to be exhausted with a sixteen per cent. solution of glucose in water, with addition of acetic acid. The solution, after treatment with animal charcoal, was to be evaporated, to separate the glucose by crystallization (!). The residue was then to be treated with absolute alcohol to obtain the crude alkaloid. We are quite unable to conjecture why a solution of glucose should have been selected for the extraction of the alkaloid, unless it were to deter experimenters from attempting to verify the alleged discovery.

Specimens of the new alkaloid were transmitted by the discoverers to physicians for physiological and clinical experiment, and reports soon appeared, from which we learn that the action of hopeine closely resembles that of morphine, both qualitatively and quantitatively. It strikes one as a little singular that the first reports, which come respectively from Dr. W. T. Smith, of London, and from Dr. M. Roberts, of New York, should have been published in German, in a Berlin medical journal, the *Deutsche Medicinal Zeitung*. The physicians named would seem to be remarkably free from the itching for fame which generally prompts men who happen to be the first to have penetrated any of the secrets of nature to proclaim in the ears of all their neighbors their discovery. That these gentlemen, however, acted in perfect good faith in their respective communications to the (distant) public there is no reason to doubt.

It was not long after the discovery of hopeine was announced before it became known that the new alkaloid was in the market as the product of the London Concentrated Produce Company. It commanded, naturally, a high price, for it could only be made from wild hops imported from North America. The latest statement of the manufacturing company is that they employ the lupulin from *Arizona* hops as the source of the alkaloid. If this is true, we only wonder that they can afford to sell it at so low a price.

When we read, however, of the use of American wild hops, put up in pressed packages, we in America rub our eyes and wonder how it is that we are not better informed about matters here at home. We had always innocently supposed that pressed hops were obtained from the cultivated plant grown this side of the Mississippi.

The therapeutic action of hopeine agrees,

according to all observers, in nearly every particular with that of morphine. Williamson assigned to it, however, a different chemical formula,  $C_{18}H_{20}NO_4 + H_2O$ , that of morphine being  $C_{17}H_{19}NO_3$ . It is noticeable that the difference is so small that experiments must be conducted with the greatest care to make it certain that it is anything more than the result of errors of observation. Williamson has himself now admitted that there is also present in commercial hopeine a variable proportion of an alkaloid isomeric with morphine, to which he gives the name of isomorphine. This discovery, however, he seems to have made only after hopeine had been made the subject of critical examinations in France and Germany, and had been shown to agree in chemical behavior in every particular with morphine.

The facts, as they appear from the full report of Dr. Dujardin-Beaumetz, of Paris, are that the article sold as hopeine differs from morphine only in the circumstance that it has a hop-like odor and flavor, which, however, is easily removed by the simplest process of purification, showing that it had been intentionally introduced into or retained in the preparation. Some samples of the alkaloid, indeed, had a flavor of oil of wintergreen in place of that of hops. Dr. Dujardin-Beaumetz is driven by the logic of the facts as revealed in this investigation to conclude that either morphine is a constituent hitherto strangely overlooked in chemical examinations of hops, or else that the article sold as hopeine was in reality the product of *papaver somniferum*; in other words, ordinary morphine commanding, under a fictitious name, ten times its legitimate price.

The profession is to be congratulated on the failure of what we cannot regard otherwise than as an infamous attempt at a wholesale fraud. There is food for thought in the fact that such a scheme, based upon the assumption that physicians were too little familiar with the scientific facts of chemistry to discover even so barefaced an imposition, was so nearly successful. On the authority of Dr. Hoffman we are assured that prominent medical men in New York have become identified unwittingly with a still more outrageous scheme, if it is true that kaskine is, as the doctor avers, nothing but *saccharum album*. We believe it is the physician's own fault if he is thus victimized. He has allowed his mind to become confused with regard to his relations to the art of pharmacy. To the pharmacist he has properly relegated the de-

tails of the processes by which his own purposes with regard to the use of remedies can be carried out. He should not expect the pharmacist to go beyond this sphere, and offer to him new combinations and new remedies, unless it be done in the way of modest suggestion. In fact, the pharmacist is now urging upon him, under one specious pretence or another, a class of preparations which are no whit better than the secret nostrums commonly known as patent medicines. If the physician has so little independence as to accept these ready-made prescriptions, whose composition is either wholly concealed or only vaguely shadowed, and generally falsified, in their alleged formulæ, he must expect that men who are unscrupulous about the means of acquiring riches will take every advantage of him; and he will have the mortification to find before long that his profession is selected by sharpers as the most favorable field for confidence operations.

#### HOW CLINICIANS ARE TRAPPED.

A CURIOUS phase in pharmaceutical history is the alterations which from time to time occur in drugs without change of the commercial name. It is a very odd commentary upon surgical therapeutics that, in the course of one or two decades, an entirely different drug should be substituted for the old *pareira brava* without the surgeons ever suspecting the alteration. A similar substitution occurred in the case of creasote. As the products of coal tar became cheaper and cheaper, carbolic acid little by little replaced creasote, so that there was a time when there was no creasote at all in the market, the article which was everywhere sold under such name being nothing more or less than impure carbolic acid. Finally, some astute observer discovered the substitution, and pointed out that the two products could be readily distinguished one from the other by their odor, creasote having the peculiar smell of smoke. This led to the discovery by many dentists of the great superiority of creasote over carbolic acid as a nerve-obtunder. So long, however, as these gentlemen were not told of the differences of the drugs they never detected the substitution by their clinical results. In regard to *pareira brava*, it would probably be a shrewd guess if we would consider that the activity of the decoction depends upon the water which is present, and that, as the surgeons use the same water with the roots of

*Cissampelos pareira* and *Chondodendron tomentosum*, the effect was identical with those, or, in other words, that the water is the most potent part of the two decoctions. Creasote and carbolic acid are undoubtedly very active agents, but their physiological activity seems to run in identical channels.

A recently discovered substitution has resulted in much, if not all, of the caffeine in the markets being theine. The alkaloids theine and caffeine have long been supposed to be identical by chemists and physiologists, but the recent researches of Dr. Mays indicate very strongly that these two alkaloids are not the same thing. Damaged tea-leaves exist in commerce in such large quantities, and can be purchased at such low rates, that manufacturers have been using them very largely for the production of the alkaloid. The medical practitioner prescribes by name, so that the demand has been for caffeine rather than for theine, and the pharmacists have largely supplied theine when the doctor wrote for caffeine. This substitution has not been detected by the general clinician, an argument, of course, for the belief in the identity of the two alkaloids,—an argument which, however, may rest upon the lack of observation on the part of the clinician. Readers of the *GAZETTE* will remember that some time ago we called attention to different results which we had obtained from the use of different makes of caffeine, and detailed a case in which caffeine, as sold by one of our most reliable druggists, failed to do good, although the caffeine prepared by Merck was successful. The trial in this case was made several times with similar response. According to the *American Druggist*, Merck's caffeine is sometimes caffeine and sometimes theine, but it is possible that the samples of Merck's caffeine which we used in this case happened to be pure caffeine.

In 1840, Martins asserted that guaranine is identical with caffeine, and his verdict has been generally accepted ever since. It is probable that the manufacturer, as he labels theine caffeine, also labels caffeine or theine guaranine when the call is for guaranine. This is all wrong. Guaranine should be prepared from guarana, theine from tea, and caffeine from coffee, and the price for each alkaloid be fixed according to its cost. We are rapidly learning the lesson that pharmaceutical chemistry, as well as practical therapeutics, must be continually unlearned as well as learned. It has not been long since we all believed that the chemists had proved that the

alkaloid of *hyoscyamus* was identical with atropine. Now, we know that there are at least two alkaloids in *hyoscyamus*, neither of which is atropine. By all means, then, let us have honest labels as well as fair prices, and not call a product something which it is not, although the chemistry of the day says it is the same thing as that which it is not.

#### MATERIA MEDICA IN MEDICAL COLLEGES.

IF there be one branch of medicine more than another that is a bugbear to medical students, it is *materia medica*. The facts of this branch of knowledge, for it is not a science, constitute an immense mass of disjointed, disconnected information. Heap upon heap to be swallowed, digested, formed into the brain-tissue of the unfortunate student for use on examination-day, most of it to be ejected the next week upon the ever-growing waste-heap of useless knowledge, very little of it having any practical importance to its possessor in after-life.

In the more advanced American colleges the uselessness of the details of *materia medica* proper is beginning to be appreciated by teachers, but in England it would seem that the old-fashioned notions still prevail, so that it is still believed that a doctor must be at the same time an apothecary. In our opinion he might as well be expected to be a surgical instrument maker. What value is it to the physician to know that the extract of Calabar bean comes from a plant that rejoices in the name of *physostigma venenosum*? The practical medical fact is as to the effect the extract has on the human organism when put into it. Why should a man be expected to know that cupræ bark comes from certain plants belonging to the genus *Remijia*, growing in Brazil? Knowledge of the physiological and therapeutical effects of quinine, and not of its natural history, add keenness to the blade with which the doctor fights disease.

The knowledge that the world possesses grows enormously. The number of facts comprised in the sum total of human acquirement is probably many hundredfold more than fifty years ago. Every decade adds enormously to the number of points which have to be covered in the study of medicine. Each year it becomes more and more necessary to cut out unessential matter. The apothecary was specialized from the physician to perform a definite task, and if the doctor is expected

to know the apothecary's business, the apothecary might as well cease to exist.

We have been led to these remarks by looking over a skilfully put together little book, which has been prepared by Dr. Prosser James, of London, as "A Guide to the British Pharmacopœia of 1885," to assist the students in fitting themselves for the examinations required in the various English colleges. With the spirit of the preface of this book we agree entirely. Dr. James says,—

"The cry for restricting the area of examinations is unheeded, and occasionally examiners pelt students with materials which they employ for no other purpose. Such highly-developed boys have lost all respect for the opinion of frogs."

We are sorry for the frogs, and still more sorry for those who are served by the physicians into which the frogs are to be transformed. For you cannot get more than a pint into a pint measure, and if the young brain is overloaded with matter of little importance it will be underloaded with that which is valuable. Materia medica courses, except of the most elementary character, are, in our opinion, out of date in medical colleges, and as despicable as cast-off mediæval armor. Elaborate, profound study of the physiological action of medicines and of their therapeutic application is the food upon which the student frog should be nurtured through the medical developmental stage.

---

THE REACTION OF THE GASTRIC SECRETION AND ITS RELATION TO CHOLERA INFECTION.

---

THE controversy between Koch and Klein as to the etiology of cholera has again been opened through the publication of a paper with the above title in the *Brit. Med. Journal*, March 13, 1886, by Dr. Matthew Hay. It will be remembered that Koch attributed the cause of cholera to the comma-shaped bacillus which obtained access to the system solely through the alimentary canal; and that, further, the vitality, and therefore the virulence, of this comma-bacillus was destroyed by an acid. The principal objection which Klein offers to this view, as to the etiology of cholera, rests upon the facts that, if the comma-shaped bacillus is the cholera virus, and the alimentary canal is the sole entrance of the cholera virus, then the other proposition, that the cholera bacillus is destroyed by acid, must fall to the ground. For,

claims Dr. Klein, the reaction of the stomach is always acid. Therefore either one or the other of these propositions must be false,—either that the bacillus is destroyed by an acid, or that it is the cause of cholera, and its entrance is solely through the alimentary canal. Now, it has been well proved that an acid does destroy this bacillus, and therefore Klein concludes that the other propositions must be false. It is at once seen, however, that Klein's argument is based on false premises; for it is by no means necessary to assume, as does Koch, that the stomach must have been previously so deranged that its contents and secretions are not acid, since it is known to nearly every one that the reaction of the stomach, except through the periods of digestion, is not acid, but is alkaline; therefore the principal objection which Klein urges against Koch's theory falls to the ground. This fact as to the reaction of the contents of the stomach has been again brought into prominence through the paper of Dr. Hay above alluded to, and in which he again has experimentally demonstrated that the reaction of the stomach in fasting, after the administration of various neutral salines, or even after the ingestion of water, had invariably an alkaline reaction. His experiments on the ingestion of water are of special importance, since he found that in animals (the cat) the reaction of the stomach when empty, or when filled only with water, is alkaline; that the inference from this fact that a similar state of affairs will hold in the case of man is supported by the fact determined by Ewald, that when water was introduced into the stomach of the fasting man, the contents of the stomach had a neutral or alkaline reaction so long as it remained in the stomach. This he ascertained by removing portions of the water from time to time by means of a stomach-tube. The practical application of these facts to the bacillus theory of cholera is very evident; for, it being acknowledged that the bacilli will be destroyed by an acid, if they are swallowed when the stomach contains food, they run the chance of being destroyed by the acid of the gastric contents. If, on the other hand, they be swallowed in water, as it is believed ordinarily to be the case, and the stomach be previously empty, then the bacilli will pass through the stomach into the intestines, where, according to Koch, they find a suitable nidus for their development. The same will happen if they be swallowed in saline solutions, as mineral waters, etc. It is evident, then, that if we accept this theory as

to the cause of cholera, it is only necessary for its prevention to keep the stomach constantly acid, and this will, of course, be attainable by keeping the stomach constantly in a state of activity; for, as long as food remains in the stomach, the reaction of the stomach must be acid. Consequently, the frequent ingestion of food in small amounts may possibly serve, by keeping the stomach acid, to prevent the passage of the bacilli. It is, of course, to be remembered that after the long fast of the night the reaction of the stomach will in all probability be alkaline, or, at any rate, neutral, and then, since it is claimed that the principal means of introduction of bacilli is in drinking-water, one should carefully avoid drinking water after a long fast, except some solid food be previously taken, and drinking water should be avoided especially before breakfast. As mentioned by Dr. Hay, it is a prevalent belief among the laity that one should not venture with an empty stomach in the neighborhood of infectious cases, and it would now appear as if this belief were about to receive some scientific support.

#### WINTER-TIRE.

IT is a curious fact that the farther north we travel the hotter habitually are the interiors of the houses. At first thought it would seem natural that the temperature in which the person lives in the house should approach more closely that of the external air, but a little consideration shows the reasonableness of the habitual action of northern nations. The man who is exposed all day to a low temperature must produce an enormous amount of caloric in order to meet the demand and keep his body warm. At eventide he naturally seeks rest, not only for wearied mind and muscle, but also for the heat-producing function. It is not always remembered that energy is expended in maintaining bodily temperature, and that when an excessive amount of such energy is required, excessive exhaustion follows. The habitual excessive draught of the winter-time upon heat production is probably one of the reasons that in the early spring every one feels so relaxed and depressed. Of course, the general relaxation and lack of energy which has received the popular name of spring-fever, and which is supposed by many to be moral rather than physical, is due in part to the fact that the winter is, at least to many brain-workers and denizens of cities, the period of excessive toil.

Nevertheless, it should be called winter-tire rather than spring-fever.

This relaxation of the system shows itself not only by the production of laziness, but also in manifestations of distinct disease. A good deal has been written in the course of the last decade concerning the fact that in children chorea is so much more frequent in the spring than at other times, but our own experience is that in this respect chorea does not stand alone among nervous diseases. Neurasthenic conditions, hysteria, and all the minor or functional nervous ills which are connected with lowered nerve tone have come under our notice as a regular spring crop, and we think most neurologists will find that the months of April and May are those of greatest professional activity.

#### PEPTONE SOUPS.

THE knowledge of the functions and chemical processes of the single digestive organs, as established within the last decade, has gradually led to the artificial reproduction in the laboratory of the digestive procedures, and to the preparation of the same digestion products as are formed in the economy. The intention not only to aid the weakened functions of the digestive apparatus, but also to procure a rest for the affected organ, and to protect it against mechanical irritation, gave birth in the first place to the preparation of a number of highly digestible articles of diet, and recently also to the practice of introducing into the alimentary canal artificially digested food-stuffs. Among these artificial digestion products the first rank is justly claimed for the artificially digested, peptonized albuminates, not only because they are indispensable for the support of the organism, but also because the assimilation of albuminates calls for the greatest activity of the alimentary organs.

There are at present very many artificially digested albuminates, so-called peptonized preparations, in the market. Unfortunately, nearly all have the disadvantage of a more or less unpleasant odor or taste, or, again, are of such a high price, that their prolonged use meets with serious objections on the part of the patients. The unpleasant odor and taste of these peptonized preparations in many cases originate from nothing less than a decomposition of the peptone, which substance is very hard to be preserved, or from prolonging the stage of digestion so far that numerous aro-

matic bye-products, such as cindal, make their appearance. Such a preparation, brought into the digestive apparatus, would of course only increase the existing trouble by intensifying the possibly already existing fermentation processes, and by inducing an elevation of animal temperature in consequence of absorbed decomposing matter. This may be especially the case with the enemata of pancreas peptones which are occasionally ordered in febrile affections. Leube-Rosenthal's meat solution, which is free from these objections, cannot be ranked with the peptonized preparations at all, on account of its scanty contents of peptone, but must be classed with the meat preparations. Dr. Jarvorski's peptone soup and a number of peptonized preparations, recently placed in the market by a reliable American firm, appear to unite all the advantages of peptonized articles, and to lack at the same time the above-mentioned objections. Jarvorski is favorably known to the readers of the GAZETTE by a number of valuable contributions to medical literature, especially by his essay on the effects of a Karlsbad cure. He claims to have used peptonized soup for the last six years, both in hospitals and in private practice, with the best results, without ever witnessing any undesirable after-effect, such as diarrhoea, which has been occasionally noted to follow the use of inferior preparations. This soup—intended for one day's ingestion—is prepared from 500 grammes (1 lb.) of the best beef, finely scraped, free from bone, fat, and sinew; to this is added 1 kilogramme (2 lbs.) of ordinary fresh meat. A quantitative chemical analysis of this soup\* gives the following results: Syntonine, 7.3 grammes; propeptone, 33.0 grammes; peptone, 40.0 grammes. In all we have, therefore, 80.3 grammes of dissolved albuminous matter. The soup is, of course, to be warmed for each meal. It is claimed that a lost appetite can be recalled after a few days' use of this soup, and that previously existing gastric pains disappear equally soon. The soup may also be employed as an enema, and may then receive additional special medication.

The peptonized nutrition is indicated in all affections in which it is desirable to raise a weakened nutrition; there exists actually no contraindication for its use. The principal indications are diminished secretion of the digestive organs in febrile conditions, in

perityphlitis caused by inveterate intestinal catarrhs with accompanying catarrhal intestinal ulceration, in gastric catarrh, hæmatemesis, anæmia and chlorosis, intestinal stenosis, gastric ulcer, carcinoma, cardialgia without emesis, and finally in convalescence after febrile affections.

The peptonized articles experience a thorough assimilation, and by themselves form a sufficient nutrition for a long time, which is proven by the increase of bodily weight under their use. This important fact is vouched for by the researches of numerous observers, of whom we mention Plosz, Catillon, Raymond, and Adamkiewicz.

It is to be hoped that the peptonized soup and other reliable peptonized articles will soon gain the same and well-deserved popularity in this country which they enjoy abroad, especially in Germany.

---

OFFICIAL REPORT ON THE CHOLERA  
EPIDEMIC IN FRANCE IN 1884.

---

THE general results and practical lessons to be drawn from the official report on the great epidemic of cholera ravaging in Southern France in 1884 cannot fail to elicit an earnest interest throughout the world. In the *Bulletin de l'Académie de Médecine* and the *Centralblatt für die Med. Wiss.*, of February 13, 1886, we find the report of Marey, based on the conclusion of the cholera commission, consisting of Pasteur and nine other prominent French physicians. One hundred and thirty-three interrogation blanks were sent to the various districts in which the epidemic reigned, one hundred and four of which, after their return, were regarded as useless for the purposes of the commission and discarded. It would lead too far to enter here into the details of the commissioners' work, and we shall content ourselves with representing the most vital conclusions arrived at, as follows:

1. In all those districts of France from which answers were obtained from resident physicians, the cholera appears to have been introduced into the single towns from previously infected places; for in three-fourths of all instances considered this mode of propagation was proven, while for the remaining one-fourth it was regarded as highly probable.

2. Considering only the observations as contained in the returned reports, the cholera is to be regarded as infecting more intensely the smaller towns than the more populous

---

\* Abstracted from the *Zeitschrift für Analytische Chemie*, vol. xx. p. 316.

centres. It is consequently a serious mistake, during a threatening or actually existing epidemic, to flee from the larger towns to country-places.

3. General uncleanness, and the abominable habit of certain classes of people to throw around the human dejections everywhere, is the chief agent of the dissemination of the disease, for during an epidemic the dejections of a person who shows no other morbid symptom than a slight diarrhoea, may contain the causes (*les principes*) of a most serious cholera.

4. The cholera is often propagated by means of water contaminated with the excrements of cholera patients.

5. Stormy and rainy weather is often observed to either precede an outbreak of cholera or intensify its severity. This refers to the contamination of the drinking-water, caused by the dirt being first dissolved, and subsequently carried away into the various reservoirs of drinking-water.

6. And, as in the larger towns the drinking-water is better guarded and protected than in smaller places, the cholera finds a greater field of propagation in the latter. Some cities, however, which derive their water from brooks, lose the above advantage.

7. In every locality such quarters are most dangerous during an epidemic which lie on low grounds in the neighborhood of the water channels.

8. The disinfection of houses inhabited by infected persons, of excrement, of clothing, and of other suspected articles, is to be conducted strictly according to the instruction of the Comité Consultative d'Hygiène, and is as such an indispensable procedure. It appears as if by this measure the epidemic has been suppressed in its initiatory phase in several instances. But, in order to be thoroughly effective, this disinfection is to be executed with the greatest conscientiousness on the part of physicians, for the appearance of the first pronounced cases, even if belonging only to the light choleriform affections, may propagate the disease by contamination of the water.

9. Old and weak people and small children are most predisposed to the cholera infection, though alcoholic indulgence, general and personal uncleanness, are likewise to be regarded as strongly predisposing agents.

10. One attack appears to confer no immunity upon a person, not even for a short time, as during an epidemic of a short duration several relapses were observed.

## Reports on Therapeutic Progress.

### ON NEW REMEDIES.

From the *Deutsche Medicinal Zeitung* of February 11, 1886, we abstract the following *résumé* of all such remedies as have been either recently discovered or presented to the profession in a novel form or combination. Though the majority of these drugs have been previously discussed in the *GAZETTE*, our readers will benefit from this condensed but comprehensive review, as prepared by MERCK, of Darmstadt.

1. *Absynthine*.—The bitter principle of *artemisia absinthium*, L. It is easily soluble in alcohol and chloroform, but sparingly so in ether, and almost insoluble in water.

This drug has been tried as a febrifuge, but without any definite results. Small doses stimulate, larger ones stupefy and produce emesis. Roux recommends absynthine in doses of  $1\frac{1}{2}$  to 3 grains twice daily, quarter of an hour before meal-time, against anorexia and constipation of chlorotic persons and convalescents. The drug is contraindicated in looseness of the bowels. Gelatin capsules are the choicest form of its administration.

2. *Acid. Sclerotinic.*, Podrogsotsky.—A light brown powder, which can be well preserved in a dry place.

This new preparation is therapeutically far superior to the old drug prepared after the method of Dragendorff. It produces uterine contractions, and seems also possessed of general hæmostatic properties. Doses of  $\frac{1}{2}$  grain applied hypodermically show a distinct effect, though for the majority of cases doses of  $1\frac{1}{2}$  grains will be found necessary. The indications of the drug coincide with those of *secale cornutum*.

3. *Acid. Chromic. Puriss.*—The chromic acid prepared at present presents almost perfect crystals, is nearly free from sulphuric acid, and is consequently but little hygroscopic.

4. *Apiol Alb. Cryst.* (parsley-camphor =  $C_{12}H_{14}O_4$ ) is contained in the seed of *petroselinum sativum*, together with apüne and an ethereal oil. It forms white needles of a faint parsley odor, is insoluble in water, but readily soluble in alcohol and ether.

Doses of  $\frac{1}{2}$  to 1 dr. cause stupefaction. In doses of 3 grains it has been successfully employed against intermittent fever and dysmenorrhœa.

5. *Aseptol* ( $C_6H_4.OH.SO_3.OH_2$ ).—Thirty-three and one-third per cent. solution of orthoxyphenol sulphonic acid,—a substitute for

phenol and salicylic acid, the antiseptic properties of which it represents. It is soluble in water, alcohol, and glycerin in every proportion. It lacks the irritating and toxic properties of carbolic acid.

Aseptol is recommended in extensive surgical operations, on account of its harmless nature. It does not destroy, like other antiseptic drugs, the finer tissues, and may consequently be advantageously employed in surgical ophthalmology. Aseptol is still active in a solution of 1 to 1000. Internally, the drug may be used in doses approximating those of salicylic acid.

6. *Atropin. Sulph. Alb. Neutr. Cryst.*—A preparation absolutely pure, neutral, and free from daturine.

Merck regards the prejudice against the German preparation in favor of the English drug as totally unfounded, and makes the rather bold statement that England does not furnish any atropine at all, and that the so-called English atropine, which many physicians exclusively call for, is invariably a German preparation.

7. *Baryum Boro-Wolframic., Baryum Oleinic., or Sulphur. Pur.*—All the preparations of baryta are to be classified among the poisons, and are hence to be used with caution.

Kobert informs us that in England the drug is used as a substitute for digitalis to regulate cardiac action.

In America the preparations of baryta are used against syphilis and scrofulosis, and especially the sulphate in doses of  $1\frac{1}{2}$  grains, in the form of duodenal (keratine) pills.

In view of the rarity of poisoning with baryta it is difficult to fix the toxic dose of the drug. It is, however, known that the carbonate may kill adults in doses of 1 dr. As antidotes may be used apomorphine and the various soluble sulphates.

8. *Benzoylcongin* ( $C_9H_{14}NO_3 - C_7H_5O$ ) is obtained as a secondary product in the preparation of cocaine; it is easily soluble in water, scantily so in alcohol, and insoluble in ether. The drug can be transformed into cocaine through methylation.

9. *Bismuth. Pepton. Sicc. Pulver.*—This preparation is thought to represent a rational form of administering the drug. It contains in 100 parts 3.1 parts of bismuth, or 3.5 parts of oxide of bismuth, in a soluble form. It is used against dyspepsia and gastralgia twice or three times daily in doses of 75 grains.

10. *Boldine.*—The preparation rapidly assumes a dark coloration when exposed to the light. It is obtained from an evergreen plant

of South America, and is said to be useful as a tonic in hepatic affections and biliary calculi. The alkaloid boldine is besides used as an hypnotic and in vesical catarrh. The drug is soluble in ether, alcohol, and in acidulated water.

11. *The Salts and Double Salts of Caffeine.*—Riegel, as is well known, has the merit of having first called attention to the virtues of the salts, and especially of the double salts, of caffeine. The caffeine preparations, especially when employed subcutaneously, exert a rapid and direct influence upon the heart, and are consequently particularly indicated when an immediate effect is called for. The absence of all accumulative action on the part of the drug enhances, of course, materially its value.

The principal indications for the caffeine salts are: valvular insufficiency in the stage of an impeded compensation, angina pectoris, and cardiac asthma. They have also been successfully tried against albuminuria and dropsy as sequelæ of heart-disease. After-effects were rarely noted. Lépine observed nervous excitement in the course of its administration, which, however, subsided after withdrawal of the drug. Quite recently, in some desperate cases, in which both caffeine and digitalis, given singly, had failed, their combination was found to be successful. Feilchenfeld, of Berlin, announced satisfactory results of the use of caffeine in the uræmia of scarlatina; 20 grains of caffeine-sodium salicyl. *pro die*, in connection with the other usual treatment, caused a rapid disappearance of albumen and also of vomiting.

The same observer noted in pleuritis, after the use of caffeine, an increasing diuresis and disappearance of the exudation. The following are the principal true salts of caffeine which have hitherto been prepared: the benzoate, hydrobromate, hydrochlorate, nitrate, salicylate, sulphate, and valerianate; of double salts are in the market the sodium benzoate (45.8 per cent. caffeine), sodium cinnamylate, sodium salicylate (62.5 per cent. caffeine), and sodium hydrobromate (52 per cent. caffeine). The citrate and tannate should also be mentioned. Riegel prescribes 12 grains of pure caffeine *pro die*, and increases the daily dose gradually up to 30 grains. The doses of the double salts can be easily deducted from those of the pure alkaloid.

12. *Calcium Hippuricum.*—A white powder, soluble in water. The action of this drug coincides with that of the corresponding sodium salt. Both drugs are employed in affections

depending upon an excess of uric acid in the body, and the dose is 10 grains.

Poulet claims that he has witnessed a rapid improvement from the use of the remedy in phosphaturia and cystitis, with a mucous and alkaline urine. The drug is further pronounced useful in scrofulosis, incipient cirrhosis of the liver, and struma. Poulet says its effects are miraculous in the uric acid diathesis.

13. *Calcium Santonicum*.—A white, tasteless powder, insoluble in water, possessing anthelmintic properties without being absorbed in the digestive tract. It is given in lozenges of 1 grain each.

14. *Cannabinon*.—A resinous body prepared from cannabis Indica. It is usually dispensed with sugar of milk (10 per cent.). Cannabinon is by no means identical with tetanine, the intoxicating principle of Indian hemp. To correct the taste of the drug, roasted coffee is used in a proportion of  $1\frac{1}{2}$  grains of cannabinon to 15 grains of coffee. The drug is reputed to be an hypnotic, which, in doses of 1 to  $1\frac{1}{2}$  grains, produces a tranquil sleep. While some observers emphasize its freedom from after-effects, Gnauck and Blumenthal observed vomiting, vertigo, and trembling after its use. Fronmüller and Hiller recommend the tannate of cannabinon as a potent and yet mild hypnotic.

15. *Quinin. Peptonat., Quinin. Phenyl.* (phenol quinine).

16. *The Salts of Cocaine—the Citrate, Hydrobromate, Hydrochlorate* (large crystals), *Oleate* (for external use), *Salicylate, and Tartrate*.—The mydriasis produced by cocaine is, according to Bradford, lessened by the addition of pilocarpine, in a proportion of 10 drops of a five per cent. pilocarpine solution to 1 f3 of a four per cent. cocaine solution.

17. *Cotoinum Verum* ( $C_{20}H_{30}O_6$ ), *Cotoinum Parapurum* ( $C_{20}H_{30}O_6$ ).—The former drug is but little soluble in cold water, but soluble in alcohol and chloroform. Internally, the remedy has been exhibited in 15-grain doses to adults and 1 to 2 grains to children, in powder or emulsion, subcutaneously in acetic ether (1 to 4); in existing pain, 30 to 60 grains of hydrate of chloral are to be added.

Cotoine is chiefly used against diarrhœa, and has been recently tried also in cholera. Para-cotoine is given in  $1\frac{1}{2}$ -grain doses to adults and  $\frac{3}{4}$ -grain doses to children. Albertoni asserts that the drug is insoluble in the gastric juice, and passes unaltered into the intestinal tract, where its absorption is effected. The drug, though unable to prevent decomposition, is certainly capable of retard-

ing this process. The same property belongs to para-cotoine, though to a less pronounced degree. Albertoni strongly recommends cotoine in the diarrhœa of lunatic, cachectic, and marasmic patients, and speaks also of its beneficial effects in the various dental affections of children and in the intestinal troubles of phthisical subjects. The combination of cotoine and the subnitrate of bismuth answers well to numerous indications. The drug is contraindicated in hyperæmia of the intestines and hemorrhage of the bowels.

18. *Colchicine*.—This drug, which is obtained from the alkaloid colchicine, is easily soluble in alcohol, chloroform, and boiling water. According to Hertel, colchicine is as poisonous as colchicine, its lethal dose being  $1\frac{1}{2}$  grains for dogs and cats. Oberlin, however, regards colchicine as much more poisonous than colchicine. Rabbits died, according to this observer, after the ingestion of  $\frac{1}{4}$  grain of colchicine in ten hours, and after 1 grain, within a couple of minutes, under complete paralysis. The drug affects principally the brain and spinal cord; opium and tannic acid act antidotal to it. In gout and acute articular rheumatism colchicine may be exhibited subcutaneously in doses of  $\frac{1}{4}$  to  $\frac{1}{2}$  grain.

19. *Fluid Extracts*.—These classes of medicine were first introduced in 1833 by the apothecary Boullay, of France, and in 1838 by Dehamel and Procter, of Philadelphia. The fluid extracts are justly credited with being easy to dose and to dispense, and with retaining their integrity to an eminent degree. They are gradually gaining popularity in Germany, thanks to the incessant endeavors of their American manufacturers.

20. *Extract. Berberidis Fluidum*.—An alterative and tonic remedy in certain skin-diseases, especially psoriasis. Its dose is 20 to 30 drops three to four times daily.

21. *Extractum Cascaræ Sagradæ Fluid.* (extr. rhamni Purshianæ).—Acts on the secretory system, and is recommendable in dyspepsia and habitual constipation, and also in dysentery. Its dose is 15 drops to 1 drachm. There exists also a dry hydrochloric extract of this drug. The following is a choice dispensation of the remedy in habitual constipation:

R Extr. cascar. sagrad. fl.,  
Syr. cort. aur.,  
Aqu. dest.,  $\mathfrak{ss}$  f3ss. M.

S.—One teaspoonful three times daily.

22. *Extr. Euphorbiæ Piluliferæ Fluid*.—Prepared from euphorb. pilulif., a native of

Queensland, and employed in asthma as a gentle stimulant and narcotic.

The active principle of the drug is soluble in diluted alcohol and water. On animals even small doses exert a toxic influence, and, if larger doses are given, respiratory and cardiac action are at first quickened, then slowed, and death ultimately ensues by paralysis of the centres of respiration and circulation. There is no accumulation tendency in the drug, and its elimination from the system takes place through the hepatic channels. The dose of the fluid extract is  $\frac{1}{2}$  to 1 dr. twice daily. Dujardin-Beaumetz employs a tincture, of which 15 drops represent 75 grains of the plant. Its dose is 10 to 30 drops.

The drug is to be used cautiously on account of its unquestionable poisonous character.

23. *Extr. Euonymi Atropurpur. Fl.*—A purge and cholagogue.

24. *Extr. Hamamel. Fl.*—Prepared from the bark of hamamelis Virginica. A tonic and astringent. The drug enjoys a just reputation in all forms of hemorrhage, especially those of the lungs, uterus, and piles. Its dose is 1 to 2 f3 *pro die*.

Black used the remedy with excellent results externally, combined with equal parts of glycerin and some starch, in grave cases of bleeding hemorrhoids. The same physician recommends also its internal use in bronchial catarrh, hæmoptysis, and atonic and colliquative diarrhoea in doses of 1 fl. dr. every three hours.

25. *Hazeline.*—A product of distillation from the bark of hamamel. Virg. It resembles in its efficacy the tincture of arnica, and is employed externally, diluted with equal parts of water, against bleeding and catarrhal conditions of the eye. Internally, it is used in doses of  $\frac{1}{2}$  dr. in water every four hours against profuse menstrual flows.

26. *Extr. Lippia Mexican. Fl.*—This drug is given as an expectorant in doses of  $\frac{1}{2}$  to 1 dr. *pro die*. A camphor (lippiol) contained in lippia Mexicana, from which the extract is prepared, is its active principle. The remedy is utilized in acute catarrh of the respiratory passages and in the dyspnoea of emphysematous patients.

27. *Extr. Piscidia Fluid. vel Siccum.*—Powerful hypnotic drugs, the former being used in doses of  $\frac{1}{2}$  to 2 dr., the latter in doses of 7 to 15 grains. The dry extract appears less reliable and not void of unpleasant secondary symptoms, such as vertigo. Frommüller em-

ployed pills, 1 grain each (2 to 4 *pro dosi*), prepared from the dry extract. The fluid extract possesses sedative properties in cough and dyspnoea.

28. *Extr. Rhois Arom. Fl.*—Recommended in affections of the bladder, urethra, and uterus, especially when depending upon excessive secretions, including hemorrhagic losses.

29. *Extr. Ustilagin. Maidis* (corn ergot, gramineæ).—Prepared from the parasite of zea mais (corn ergot).

This fluid extract, which is given in doses of 10 to 12 drops, is a substitute for secal. corn., and is said to be preferable to the latter in producing no pains, and in being relatively harmless.

30. *Extr. Viburni Fl.*—Prepared from viburnum prunifolium. According to American authoritative assertions a valuable tonic and sedative in threatening abortion, in dysmenorrhœa, and the discomforts subsequent to confinement. Its dose is  $\frac{1}{2}$  to 1 fl. dr. four times daily.

31. *Helenine* (alant-camphor) ( $C_6H_{10}O$ ).—Colorless, crystalline needles of a neutral reaction, which are almost insoluble in water, but easily soluble in hot alcohol, ether, and ethereal oils. Rorab believes that from its antiseptic virtues helenine may be utilized in tuberculosis, malaria, and catarrhal diarrhoea. One part of the drug, according to this observer, is able to protect 10,000 parts of urine against decomposition. Valenzuela obtained excellent results from this drug in pertussis and chronic bronchitis, and noted a diminution of the cough, dyspnoea, and pectoral pains to invariably follow upon its use. A narcotic effect was never observed. Besides, helenine produces a tonic effect upon the digestive functions, and may therefore be given even to phthisical patients affected with grave diarrhoeas.

32. *Homatropine* (Ladenburg, Merck).—A considerable reduction of its price is all the information obtainable regarding this drug.

33. *Hydrargyr. Tannic.*—Brown-greenish scales, forming a gray-green powder on being rubbed up; its proportion of mercury is at least forty per cent. The preparation is decomposed by concentrated acids and alkalis under separation of microscopically visible mercury-globules. Diluted muriatic acid does not materially affect this preparation. On the addition of water and acetic acid tannic acid is precipitated. The drug has an indisputable value as a mild antisypilitic remedy.

The separation of mercury is so fine that a

quick absorption results in the intestines. This medication has consequently been aptly called "an internal inunction cure." The drug is given with four times its quantity of sugar of milk in  $1\frac{1}{2}$ -grain doses four times daily in wafers.

In weak patients, and such as are predisposed to diarrhoea, Lustgarten prescribes the remedy in combination with tannic acid after the following formula :

R Hydr. tannic oxyd.,  $1\frac{1}{2}$  grains;  
Acidi tannici, 1 gr.;  
Pulv. gummosi or sacchar. lactis, aa 7 gr.;  
Pulv. opii,  $\frac{1}{4}$  gr. M.  
S.—As one dose.

34. *Iodoform*.—This preparation (iodoform with gelatin) is intended for insertion into wounds, opened buboes, and fistules. Besides, it is used in gonorrhoea and other affections of the urethra, and also in the puerperal affection of the uterus.

35. *Kalium Osmicum* ( $K_2O_5O_4 + 2H_2O$ ).—A violet-red powder, easily soluble in water. Its practical employment is somewhat marred by its hygroscopic tendencies, and many physicians prefer, hence, the salt to the acid. The indications of the acid coincide with those of the salt.

Both preparations enjoy a certain reputation in peripheral neuralgias, where, according to Neuber's recommendation, they are employed hypodermically. Mohr speaks highly of a one per cent. watery solution as a remedy of rheumatic ischias. Szumann and Eulenberg recommend parenchymatous injections of osmic acid against goitre, while Delbaille employed injections into sarcomata and lymphomata.

Quite recently the drug was proposed by Wildermuth as an excellent medication of epilepsy when combined with bromide of potassium. Wildermuth gives doses of  $\frac{1}{12}$  to  $\frac{1}{8}$  grain in pills with bolus alba. These pills are best coated, as they are apt to produce gastric disturbances when used for a long time.

36. *Keratin. Pepsino Paratum*.—This keratine is not affected by the acid contents of the stomach, as by the action of pepsine and muriatic acid it is freed from all substances which are soluble in the stomach; the preparation is only dissolved by the alkaline juice of the intestines. It is a gray powder, and has recently been warmly recommended by Dr. Unna, of Hamburg, as a suitable coating for all such pills the solution of which is desired exclusively in the intestines. Consequently, when prescribing arsenic, sugar of lead, ni-

trate of silver, phosphorus, and anthelmintic remedies in pill form, keratine can be used with great advantage.

37. *Liq. Ferri Peptonat*.

38. *Lithium Hippuric*.—This drug is employed in doses of 7 grains against affections depending upon an excess of uric acid.

39. *Naphthalinum Purissimum Alcohol. Depuratum*.—Being insoluble in water, alkalies, and acids, this drug can be brought into the system in relatively large quantities without experiencing any material absorption in the digestive tract. Rossbach claims to have the drug successfully exhibited in doses up to 75 grains in acute and chronic diseases of the intestines, in infantile diarrhoea, incipient typhoid fever, and tubercular intestinal affections. Priebram, Schwarz, and Ewald speak likewise well of the value of naphthaline, and agree that the drug possesses eminent antiseptic properties, and does not alter the principal systemic functions, such as circulation and respiration. The single dose is 15 grains, and 75 grains may be given *pro die*.

Externally, naphthaline is used combined with equal parts of vaseline against scabies, herpes tonsurans, favus, and eczema marginat. Oil of bergamot is, in a proportion of 1 part to 40 parts of naphthaline, an efficient means to disguise the taste of the latter.

Rossbach also uses naphthaline in the form of irrigations. Fifteen to seventy-five grains of the drug are melted in two to four fluid-ounces of water, mixed with twenty to forty fluid-ounces of hot water, and gradually cooled down.

Recently Wolf called attention in an American journal to the fact that naphthaline, dissolved in the proportion of one to five hundred in hot water, excelled alcohol as a preserving medium of anatomical preparations.

40. *Pelletierine* (punicin), the alkaloid of iort. punic. granat. ( $C_{16}H_{30}O_2$ ) and *Isopelletierine*, are powerful anthelmintic drugs. There also exist a tannate, a sulphate, and a valerianate. The sulphate is a body of a thick fluid consistency, and in order to dispense it readily a ten per cent. solution is best kept ready, which is then dispensed in 1-drachm doses.

The tannate is a dry powder, and is given in 20-grain doses in water. The following combination of the sulphate and of tannic acid have been found especially effective :

R Pelletierin. sulph., gtt. viii;  
Acid. tannici, gr. vii;  
Aq. dest., fʒi. M.

S.—Take in one or two doses within half an hour; after that a laxative is to be taken.

Samples of *tænia serrata* which lived several days in water at a temperature of 98° (F.), with one per cent. of chloride of sodium and one-tenth per cent. of carbonate of sodium, grew lifeless within a couple of minutes after the addition of one one-hundredth per cent. of pelletierine. As the drug increases the arterial pressure, it is contraindicated by the existence of an aneurism.

41. *Pyridine Puriss.* (nitric crystal, sulphur. crystal).—Pure pyridine was recommended against asthma originally by Germain Sée, of Paris. He orders about one drachm to be poured out on a plate, which is placed in a corner of the sick-room, and in this manner makes the patient inhale for about twenty to thirty minutes the pyridine vapors mixed with atmospheric air. A repetition two or three times of this procedure is said to be sufficient to relieve the dyspnœa.

The salts of pyridine serve for internal application.

Pyridine is, when exhibited as an inhalation, rapidly absorbed, and can be demonstrated in the urine a couple of minutes after its inhalation.

42. *Sanguis Tauri Pulv.* (ox-blood powder).—An odorless pale-brown powder, soluble in cold water, giving a blood-red color. The ox-blood powder is recommended as an artificial food for children in doses of 2 drachms, and for adults in doses of 6 drachms, three times daily in water, wine, milk, or black coffee, and is to be taken at meal-time.

43. *Serum Sublimat.* (one per cent. to ten cent.).—The union of mercury and of albumen is better borne by the system than the pure chloride of mercury. Lister recommends the employment of serum-sublimate for the saturation of surgical dressing material, such as gauze, cotton, and lint.

The one per cent. serum sublimate is a fluid, while the ten per cent. preparation has the form of thin plates.

44. *Terpinhydrat.* ( $C_{10}H_{16} + 3H_2O$ ).—Colorless crystals of a faintly aromatic taste. Lépine advocates the use of this drug as a good expectorant in chronic and subacute bronchitis, and in chronic nephritis in place of the oil of turpentine. Its dose is 3 to 6 grains.

The high efficacy of turpentine in diphtheritis being indisputable,—Possel wrote as early as 1880 about this subject,—it is to be expected that terpine may likewise be useful in this affection. The hydrate of terpine is soluble in boiling water, in cold and boiling alcohol, chloroform, and ether, but sparingly soluble in turpentine.

45. *Urethan. Puriss.* ( $NH_2CO_2C_2H_5$ ).—The ethylic ether of carbaminic acid: white crystals, easily soluble in water, odorless, but tasting somewhat like saltpetre.

V. Jacksch. found experimentally on animals that doses of  $\frac{1}{2}$  gramme pro 1 kilogramme of bodily weight produced no toxic effects.

The drug evinced, as alleged, hypnotic virtues in very different affections, without in any way calling forth any secondary untoward symptoms, as is nearly the rule with all other hypnotics.

#### THE RADICAL CURE OF HYDROCELE BY ANTISEPTIC INCISION.

At the present time there may be said to be three methods prominently before the profession for the radical cure of hydrocele,—the time-honored injection of iodine, antiseptic incision, and suture of the tunica vaginalis and the scrotal skin (with drainage), proposed by Volkmann, and the more recent method of the injection of carbolic acid, suggested by Levis, of Philadelphia. An important modification of Volkmann's method has been adopted by Bergmann, of Berlin. It consists in the extirpation of all the tunica vaginalis save that covering the testicle. DR. WILLIAM T. BULL, in a paper read before the New York Surgical Society (*New York Med. Journ.*, March 13, 1886), states that he has performed the operation of antiseptic incision upon fourteen patients. One of these cases was operated on at the same time for the cure of a large hernia, and death followed from peritonitis, so this case may be therefore thrown out of consideration. The other thirteen patients all made satisfactory recoveries but one.

Of the twelve successful cases, ten were hydroceles of the tunica vaginalis, and two were hydroceles of the cord. The two latter had existed each for three or four years. The duration of the former was in six cases "about one year," in two cases between one and two years, in two others three years and over. As regards previous treatment, two had been injected with carbolic acid (one of them on two occasions), one with tincture of iodine, and the rest had been tapped or received no treatment. At the time of operation but one sac was observed to be decidedly thickened. This contained one or two calcareous patches, which were cut out. One hydrocele of the cord, as large as a horse-chestnut, was found to be made up of five or six cysts. This case car-

bolic acid had failed twice to cure. The other hydrocele of the cord was in reality a compound cyst of the head of the epididymis. A number of cysts of the size of a split pea were clustered about the epididymis, and contained within a larger cyst which reached up on the cord for an inch and a half.

In ten cases Volkmann's operation was done; in two (the cysts of the cord and epididymis) the entire parietal layer of the tunica vaginalis was excised. Bichloride of mercury of the strength of 1 to 5000 was used in moderation to irrigate the wounds, and extreme care taken to tie all bleeding points. The incisions were long enough to reach from the top of the sac to the bottom of the scrotum. The tunica vaginalis was united by a continuous catgut suture to the skin, and two or three deeper sutures were applied to hold the two halves of the sac in contact. A further effort was made in this direction by the application of the dressing in such a way as to hold the serous surfaces together. Bone tubes were used in three cases, rubber drains in nine. The latter were shown to be preferable. The bone tubes softened rapidly, but were not absorbed at all, and did not adapt themselves to the sinuities of the wound. The dressing was uniformly of peat-bags (with bichloride) and bichloride gauze, with occasionally a strip of iodoform gauze over the line of suture, and an outer layer of absorbent cotton. There was no instance of excoriation or marked erythema of the skin. The penis protruded through the middle of the dressing, which was applied snugly with crinoline bandages. One or two patients had to be catheterized for twenty-four or forty-eight hours; but this was the only discomfort experienced. The career of the wounds was in all cases aseptic, and without fever. A temperature of 100.6° on the evening of the second to third day, without any acceleration of the pulse, was the greatest constitutional disturbance. With little variation, the first dressing remained in place till the seventh day. On its removal the tubes were withdrawn, and a lighter dressing of iodoform or boric-acid ointment and plain absorbent cotton was applied supported by a suspensory bandage. This was changed as often as it became soiled. The patients were allowed to move about a day or two later, but were not, with one or two exceptions, discharged till the sinuses were healed. As a rule, primary union was found on removing the first dressing. In six cases this was *complete* except where the drainage-tube emerged; in five,

besides the "drain sinus," there was a strip of granulations along a portion of the line of suture, forming a quite superficial ulcer, which scabbed over rapidly. In one case primary union was secured, but an accumulation of pus (without fever) made it necessary to break down the adhesion, and the abscess required two months to heal. The sinuses left after removal of the drain healed without special attention. There was no instance of orchitis, or epididymitis, or inguinal adenitis, and the induration and thickening along the cord, which have been noted by others, disappeared by the time the sinus closed, or soon after.

As regards the *time* occupied by the treatment, the shortest period of confinement to bed was seven days, the longest three weeks; the average stay in bed in all twelve cases was ten days. The shortest stay in hospital was ten days, the longest sixty days, the average twenty-seven days. Two cases were much slower in healing than the rest,—one from the occurrence of the abscess just referred to, the other from unexplained causes. Dr. Bull has had the opportunity of examining five of these patients one year after the operation, and they remain cured. Two have been seen six months, two others four months after operation, and are free from recurrence. All were operated upon under ether except one. In this case cocaine was used, with the effect of rendering the operation absolutely painless.

The result of the treatment of these thirteen patients may be briefly stated as follows: One has died from mercurial poisoning. Twelve have recovered,—ten after incision with suture, two after excision of the sac. The wounds, except in one case, have healed without pain or constitutional disturbance, and on an average in twenty-seven days, ten of which were spent in bed. Nine out of twelve patients are known to have had no recurrence at a period of from four to twelve months after the operation.

The possibility of recurrence is generally admitted, though alleged to be rare, and the cause is found in the failure of the two serous surfaces to unite fully after suture. Small cavities are left which become the seat of a reaccumulation. In order to obviate this, Von Bergmann has proposed the extirpation of the parietal layer, and carried it out in twenty cases, as mentioned above. The wounds healed without febrile movement on an average in ten to twelve days, and no recurrence has yet been seen.

The technique of the operation needs but slight mention. The incision should reach from the top of the sac to the bottom of the scrotum, and Dr. Bull prefers to place its lower end behind the testicle in order that the drainage-tube may be out of the way. The tunica is best removed by stretching it on the fingers and cutting through and pushing back the loose connective tissue with blunt scissors. It is much easier than the extirpation of a hernial sac where the presence of a truss has made the layers adherent. The membrane is removed close up to the epididymis and testicle. It is important to be very painstaking with the ligatures, and to have the drain long enough to pass beyond the testicle. In other respects one proceeds as in Volkmann's operation, but the suturing of the wound is simpler, as the tunica is absent.

#### ABDOMINAL SECTION FOR INTESTINAL OBSTRUCTION.

The subject of abdominal section for intestinal obstruction is attracting so much attention at present that we give in full the account read by MR. A. E. BARKER before the Clinical Society of London of a case of acute intestinal obstruction, followed by acute general peritonitis, in which abdominal section and release of the implicated bowel was performed, the peritoneum thoroughly sponged out, and in which rapid recovery took place (*Brit. Med. Journ.*, March 6, 1886).

The patient was a man, aged 23, who had enjoyed good health with the exception of flatulent dyspepsia, up to Saturday, November 14, 1885. At 7 P.M. on that day he had a loose motion, with a feeling of sickness, and three or four minutes later was seized with a violent pain in the abdomen, and fell down, rolling about in acute suffering. This pain commenced at a point midway between the umbilicus and right groin. At 7.30 he began to vomit, and continued to do so through the night and next day, until Monday evening, when Mr. Barker was sent for. At the onset, he was seen by Mr. Knaggs, of Camden Road, who gave large enemata, with opium internally, and hot fomentations over the abdomen. This treatment was continued with much judgment for the next forty-eight hours, but with no relief. On the contrary, the pain increased, and became general over the whole abdomen; the vomiting continued of a grass-green color, but never became stercoraceous; the belly grew more and more distended, and the centre of acute tenderness shifted to the left side

of the umbilicus. The peritoneum also began to fill with fluid; there was complete obstruction of the bowels from the first, and no flatus was passed. No distinct tumor was to be felt anywhere. When he was seen by Mr. Barker on Monday evening, the condition was very grave, and he at once decided to perform abdominal section, regarding the case as one probably of obstruction from a constricting band, or from volvulus of the small intestine. With strict antiseptic precautions, the abdomen was opened in the middle line, from the navel to the pelvis, and was found to contain much flaky serum and free gas; the intestines were coated with lymph, and moderately distended. The small intestine was now passed through the fingers from below upwards, until the middle third of the jejunum was reached. When this was drawn upon, there came a sudden rush of fluid through the portion held in the fingers, and the next moment there came out a loop of bowel deeply congested and ecchymosed, and distended to about three or four times its normal girth, and containing much fluid. Beyond this loop the gut was distended and moderately congested, but was sharply marked off against the implicated loop by the absence of ecchymoses. The bowel was now passed through the fingers downwards, to make sure that no other obstruction existed, and then the cæcum and vermiform appendix were turned out of the wound and examined with the same object; they were quite sound, though sharing in the inflammatory distention and congestion to a slight extent. The hand was now passed into the abdomen, and every part of it was explored, but nothing further was found. The gut having been carefully cleansed was now replaced, and the whole abdomen was mopped out with carbolyzed sponges, passed into every recess on long holders. The greatest accumulation of inflammatory products was found in the flanks and pelvis, and required repeated sponging. When the whole cavity had been cleaned, the wound was united with seven deep and two superficial carbolyzed silk sutures in the usual way, and was dusted with iodoform and dressed with salicylic wool, secured with a broad binder. The patient bore the operation well on the whole. He had a good deal of pain in the night, and vomited twice before morning. The vomited matter was no longer bilious, but consisted of watery altered blood. It came up for the last time at 9.30, twelve hours after operation. The patient progressed extremely well after this, the peritonitis disappearing rapidly. The

wound was dressed for the first time on the fifth day, and was then found united by first intention. Five of the stitches were taken out, and the wound was supported by broad strips of sticking-plaster applied directly to the skin with salicylic wool and a binder over all. On the seventh day, the remaining stitches were removed, and the wound was supported as before. On the eighth day, a motion was passed spontaneously, and again on the ninth. These motions were stained with old blood. On this day, owing to an error in diet, he vomited and burst open the upper two-thirds of the wound, in spite of the strapping, and a knuckle of the intestine protruded. On seeing this six hours later, Mr. Barker removed the dressings, cleansed the protruded gut under the spray, wiped out the abdomen and the wound, and replaced the gut. The opening was closed as before, and similarly dressed. The temperature in the rectum rose on the night following to  $102^{\circ}$ , but beyond this there were no disquieting symptoms throughout convalescence, the patient being able to take light solid food for a couple of days later. The wound healed in great part by first intention, but some of it by granulation. (Patient shown.) In reviewing this case, Mr. Barker dwelt upon the following points: 1, the nature of the obstruction; 2, the performance of abdominal section in the midst of acute general peritonitis; 3, the rapid disappearance of the latter after operation. He pointed out that, from a comparison of this with recorded cases, there could be no doubt that it was a case of volvulus of the jejunum, a very rare condition. The whole case corresponded closely with the few others on record, none of which had been operated on except one. The onset of general peritonitis he regarded as an extra reason for early operation in such cases, and showed that this view was supported by pathological reasoning and clinical experience. The rapid disappearance of the peritonitis, due to the release of the intestine and cleansing of the abdominal cavity, was then commented on; and it was pointed out that the good result was besides in great part to be attributed to the judicious treatment of the case from the first with opium and enemata, and the comparative rest that the bowels were then placed in up to the time of operation, which was not delayed a moment after it was evident that other means had failed. That such an operation could only be successful when performed early, and under the strictest antiseptic treatment, was also pointed out.

### VARICELLA AND ITS DIAGNOSIS.

DR. HENRY ASHBY gives the following tabular contrast as to the points of diagnosis between varicella and varioloid (*Archiv. of Pediatrics*, February, 1886):

VARICELLA.	VARIOLOID, OR MODIFIED SMALLPOX.
<i>Incubation.</i> —Thirteen to sixteen days.	Twelve days.
<i>Premonitory Fever.</i> —A few hours.	Two to three days.
<i>Premonitory Symptoms.</i> —Mostly nil.	May include pain in back, headache, vomiting, delirium, drowsiness, convulsions, and fever.
<i>Rash.</i> —Red spots, in a few hours becoming vesicular, drying up in three or four days, leaving crusts; come out in crops on four or five successive days on scalp, body, limbs, face, and mucous membranes. Vesicles mostly monolocular.	Red, shot-like papules and soft palate, appearing first on face and wrists; during next twenty-four or forty-eight hours over body and limbs; papules become vesicular after two or three days, and pustules by eighth day of disease, or more frequently dry up, leaving scabs.
<i>Temperature.</i> —Intermittent in character.	Sudden rise, reaches height when the rash is fully out, followed by a speedy fall. Secondary fever slight in modified cases.

### THE INFLAMMATION OF THE LIVER AND HEPATIC ABSCESS.

DR. GEORGE HARLEY has been publishing in the February numbers of the *Medical Press* a series of valuable papers on the causation, the diagnosis and treatment of hepatic abscess, and inflammation of the liver.

His ideas as to treatment are so novel, and seem to be so valuable, that we publish a tolerably full abstract of his methods, for the surgical procedures hitherto adopted in the treatment of diseases of the liver have been mainly confined to measures designed to promote the evacuation of abscess-cavities, or of cystic growths; but little has been attempted beyond this, inasmuch as the organ in question has been considered to lie beyond the line of direct operative interference, on grounds, it must be admitted, that appeal less convincingly now than in the days antecedent to modern surgical improvements. Dr. Harley, however, advocates so novel, and at first sight so startling, a modification of the usual treatment of hepatitis, that special attention is certain to be attracted to his utterances and experiences.

In a case of acute hepatic congestion, according to Dr. Harley, the first thing is to enjoin strict rest. The second is to put the patient on low diet. The third, to freely clear out the bowels. The fourth, to relieve the local discomfort by the application of hot, thick, and large linseed-poultices. The fifth, if there be signs of threatening supuration, to apply a freezing mixture of ice and salt, or leeches, or even cupping-glasses, over the painful hepatic region. It is sometimes surprising how speedy and complete is the relief afforded by this indirect mode of local depletion; but the striking novelty of Dr. Harley's paper is a much better mode of relieving an engorged liver, to which he has given the name of hepatic phlebotomy, from its being in reality a mode of bleeding the liver itself. Euonymin, iridin, leptandrin, podophyllin, and all other forms of hepatic purgative stimulants, are totally inadmissible in cases of hepatic congestion. Mercury is here our sheet-anchor, both as a purgative and an antiphlogistic.

When hepatitis, no matter what its variety may be, has once reached the congested indurated stage, Dr. Harley found much benefit from puncturing the capsule of Glisson.

So soon as the liver of a patient is not only enlarged, but hardened, in consequence of the pressure to which its inflamed tissues are subjected, as the result of their engorgement and confinement within their inelastic fibrous covering, there can be no more effectual way of giving relief than by puncturing the capsule of Glisson. Dr. Harley was led to adopt this plan of treatment from his experience of the benefits derived from puncturing the distended sheath of the sciatic nerve in cases of acute neuritis, which is done on precisely the same principles as the surgeon punctures the tense unyielding tunica albuginea to relieve pressure on the inflamed secreting structures of the testicle in cases of orchitis.

The operation of puncturing the capsule of Glisson is done with a trocar of the diameter of a No. 2 or 6 catheter, according to the gravity of the case, inserting the trocar in each lobe of the liver, and allowing it to remain for several minutes.

In support of the truth of these statements Dr. Harley reports the case of a man, aged 52, who came to him with a liver enlarged and indurated in all directions, in which this operation produced in eighteen hours the greatest relief and a general decrease in the size of the liver.

As regards direct bleeding from the liver, or hepatic phlebotomy, an indication which is generally acknowledged to exist, Dr. Harley shows that cupping or leeching the abdominal parietes can be of no avail; for since none of the hepatic blood-vessels communicate with those of the abdominal parietes, it is evident that it must be utterly impossible that the withdrawal of blood from the vessels in the abdominal parietes can have any direct effect upon the quantity of blood in the liver.

This is, however, according to Dr. Harley, capable of being accomplished with perfect safety by piercing the liver with a lung-trocar, from left to right, taking care only to avoid the large vessels which are in the neighborhood of the transverse fissure. The trocar should, therefore, be kept in a line between the centre and the upper convex border of the liver, in which position there are few large vessels, and there is, therefore, no risk of the entrance of air into the veins. Dr. Harley reports a case in which this plan was pursued with the greatest benefit.

In this connection the *Medical Press* for February 24 refers editorially to this operation as follows: "It is needful that the most careful and cautious consideration should be given to the subject in all its details ere an unqualified approval can be given to an operation, the risks and possible dangers of which have not yet been fully discussed. No good result can follow the hasty and general adoption of any surgical improvement to which recognition is accorded on first and apparently favorable results; and although in Dr. Harley's experienced hands, guided by a long and extensive acquaintance with liver-disease in all its varieties, the best consequences may safely be expected to follow the adoption of the course he recommends, it must still be remembered that only a few practitioners are possessed of the skill and knowledge requisite to enable them to form an accurate diagnosis and a sure judgment respecting the cases appropriate for treatment by an unfamiliar and important operation. We do not desire, or intend, to disclaim the advantages which Dr. Harley considers to be identified with his proposal; we only urge that it shall be fairly, fully, and conscientiously considered in every aspect before its adoption is made an article of faith among practitioners, and especially young practitioners. It promises to be a salutary proceeding according to the evidence adduced by its originator; and in the best interests of medicine and of suffering humanity it cannot be too surely grounded on such

proofs of efficacy as the skilled and experienced can alone assign to it in the earlier stages of its employment as a remedial procedure."

As regards the treatment of hepatic abscess Dr. Harley is, in general, in accord with the views held by the majority of the medical profession. He believes that the best plan for opening an hepatic abscess which has not pointed is with a trocar, either with or without the aid of the aspirator. Free incision with a knife, in his opinion, when the abscess has not pointed, but adds to the risk without yielding any proportionate advantage to the patient. In any case, after evacuation of the pus a drainage-tube ought to be inserted in the sac of the abscess, and the cavity well washed out with tepid antiseptic water. At the same time germicides, in the form of salicylic, carbolic, or mineral acids, along with quinine, should be given, and the general health of the patient carefully attended to, for even in the most favorable cases liver-abscess is invariably a most exhausting and dangerous affection.

As regards the diagnosis of hepatic abscess, Dr. Harley calls attention to the fact that it should not be forgotten that suppuration of the liver is always preceded by a longer or shorter period of hepatitis; the severity of the pain is, however, in no instance a criterion of its severity. For we may have great pain with slight inflammation, and scarcely any pain with a considerable suppuration. A superficial abscess is always more painful than a deep-seated one. If during the ordinary course of a hepatitis the patient should suddenly complain of chilliness or shivering,—when there is no reason to suspect occlusion of the bile-duct,—and the rigor is immediately followed by an increase of temperature and an aggravation of the constitutional disturbance, while at the same time the hepatic tenderness is increased, suppuration may be suspected to have set in.

There is always a disinclination to take food, and if the suppuration has existed for some time, there is frequently a well-marked diarrhoea, with or without blood. Vomiting also occasionally occurs, but it is not a common symptom. In some, though not in all, cases of liver-abscess, sneezing, coughing, and deep inspiration causes pain, and then the patient cannot lie comfortably on his side.

The most notable sign of liver-abscess, when there exists the before-mentioned hepatic symptom, is, in Dr. Harley's opinion, high temperature, varying from between 102° and 105°. The fever is often associated with

hectic and sweating exacerbations. The more superficial the abscess is, the easier is it diagnosed. When situated at the lower margin of the liver, where it projects from under the false ribs, the abscess appears as a smooth, hard swelling, with a feeling of more or less distinct fluctuation about it. On the other hand, when it is situated within the margin of the ribs, palpation furnishes no signs whatever of its existence. Even firm pressure causes no increase of pain beyond, perhaps, a feeling of a more diffused discomfort. Smart percussion, on the other hand, in general cannot be readily tolerated. When the abscess is large it causes bulging of the intercostal spaces, even before it actually points, and fluctuation may then be perceptible. But this is not often the case until it points, even when the abscess is below the ribs. To sum up, then, it may be said that all that we have to guide us in the diagnosis of the majority of liver-abscesses is the existence of pain in the liver, increased on pressure, associated with rigors and high temperature, and the other constitutional symptoms above mentioned. But as the combination of even all of these is not always conclusive, in cases of doubt it is true wisdom to have recourse to an exploring trocar.

The one Dr. Harley recommends to be employed in the general run of cases is a fine, six-inch long French instrument, but one eight inches long, the diameter of a No. 3 English catheter, may be used. There is, comparatively speaking, but little risk in the employment of either, if care be taken not to insert them too near the ribs, so as to avoid the danger of the instrument being either bent or broken by the ribs during a sudden and forcible act of inspiration, and keeping the point of the instrument from the vicinity of the larger blood-vessels in the neighborhood of the transverse fissure.

#### *INFLUENCE OF ANÆSTHESIA BY THE INHALATIONS OF NITROUS OXIDE UPON VARIOUS FUNCTIONS OF THE ECONOMY.*

The researches of Drs. Jolyet and Blanche in 1873 demonstrated that anæsthesia, produced by the inhalations of pure nitrous oxide, is always accompanied by a state of asphyxia sufficient in itself to produce anæsthesia. DR. LAFONT (*La France Médicale*) thinks that this asphyxia concomitant on the anæsthesia produced by nitrous oxide may be a source of serious danger. In support of

this fact, he refers, first, to the production of death of the fœtus and abortion at four and one-half months of pregnancy; second, the appearance of chlorosis in a young, growing girl; third, the appearance of epileptic symptoms in a young woman who had been exempt from them for many years; fourth, the appearance of albuminuria in a case of mitral insufficiency; and, fifth, diabetes mellitus, observed twice in the same patient, following each time the administration of nitrous oxide. This latter point Dr. Lafont has studied upon himself. He found, in the first place, that his urine was normal, that is, it was free from sugar, and he found that, two hours after two successive inhalations of nitrous oxide, after a few minutes' interval, his urine contained 1.65 parts of sugar per thousand. Six hours afterwards there were 18.40 parts per thousand, whilst three days afterwards the quantity had been reduced to 3.95 parts, and on the fourth all trace of sugar had disappeared. Dr. Lafont also found that in the dog glycosuria was produced after the inhalation of nitrous oxide. This condition of glycosuria was found to depend upon an actual increase of sugar in the blood, the amount found increasing from one and one-half parts per thousand, which is said to be normal, up to three parts per thousand.

In following up still further the action of nitrous oxide, Dr. Lafont found that the influence of this gas on the respiration varied with the animals experimented upon; that in man the respirations became more ample without changing their rhythm. In the rabbit, at the commencement of the inhalations, respiration becomes more frequent and fuller, but becoming slower at the moment that anæsthesia is complete. In the dog the respiratory movements gradually increase in frequency and fulness up to the moment of anæsthesia, at which time the movements are panting, and may become suddenly arrested, the stoppage being more or less prolonged, and sometimes proving fatal. As regards the influence of nitrous oxide on arterial pressure, Dr. Lafont found also a variation, according to the animal experimented on. On the rabbit the pressure remains stationary, or becomes slightly lower. In the dog it rises gradually up to the moment of anæsthesia, and then becomes stationary. At the commencement of the inhalations there is an increase in the frequency of the pulse in all animals. When anæsthesia is complete, the movements then become slower, and the heart may often be arrested. This slowing of the pulse may

persist even after recovery of consciousness. The increase of pressure observed in the dog Dr. Lafont found to be due to the condition of agitation of the animal, while the slowing of the pulse he attributes to stimulation of the pneumogastric nerve, since it is absent when atropine is given.

#### RESORCINE AND COCAINE IN WHOOPING-COUGH.

According to a note appearing in the *Centralblatt für die Medicinischen Wissenschaften* of February 13, 1886, DR. MONCORVO feels satisfied that resorcine is a valuable drug in the treatment of whooping-cough. Having used resorcine for a long time alone, and also—as is his habit at present—immediately after the application of a ten per cent. solution of muriate of cocaine to the larynx and pharynx, he found that the combined use of these drugs furnished better results than could be obtained from their application singly.

In this connection we recall that in the *Berliner Klinische Wochenschrift*, No. 44, 1885, DR. J. PRIOR, of the University of Bonn, eulogized cocaine as the remedy *par excellence* in pertussis, while, as our correspondent from Berlin assures us, the remedy has received an exhaustive trial at the Charité, and has been found to be almost wholly useless. In this controversy—Henoch *versus* Prior—we are probably safe in following the former as the best guide in the field of pædiatrics.

#### A CASE OF RECOVERY AFTER GASTRO-ENTEROSTOMY FOR CANCER OF THE PYLORUS AND STOMACH, WITH A NEW METHOD OF SUTURE.

Since first designed and performed by Woelfler in 1881, gastro-enterostomy has been undertaken at least twenty times abroad. In sixteen of these cases it was done on account of advanced carcinoma of the pylorus with ten deaths, and in four with non-malignant pyloric stenosis with one death. Most, if not all, of the sixteen were desperate cases for any operation. In the *Brit. Med. Journ.* for February 13, 1886, MR. ARTHUR E. BAKER reports the first successful instance in which this operation was performed in England, and he describes a new method of suture, which seems likely to offer advantages in the future.

The patient, aged 37, the mother of eight children, one of whom died of a malignant growth in the neck in infancy, began to suffer from severe gastric disturbance a year and a

half-ago. This consisted of great sickness and vomiting, with pain in her stomach. Since then hardly a day passed without retching; this was always worse after dinner, but was less in the evening, and when the patient was at rest.

On August 25, 1885, the patient noticed a lump, about the size of a walnut, in the epigastric region, and, at the same time, the vomiting and pain became much worse: the latter was aching and dragging in character. The tumor had grown larger since, especially within the last three months. When first noticed, the lump, the patient thought, was a little more to the left than now. It appeared irregularly nodulated from the first.

On admission into University College Hospital on December 19, 1885, the chief complaint was pain in her left side, and great weakness and loss of flesh (weight, seven stone three pounds). During the week preceding, her attacks of sickness had not been so severe; she had had only four or five. The vomit was watery and frothy, but never consisted of food, and never showed traces of blood; there had been much constipation for a long time.

*State on Admission.*—In the middle line of the body, about two inches above the umbilicus, was a hard, nodular swelling, about the size of an egg, very superficial, and very mobile. It shifted spontaneously from side to side during the day, and ascended a little, but did not descend below the point indicated. When in the middle line, it pulsed with the stroke of the aorta. It was tender on pressure, and caused most suffering when it lay towards the left side. There was no deficiency of resonance to be detected over it, and there was no gastric dilatation; the tumor moved with respiration; the abdominal organs appeared quite healthy.

On December 28 was made a careful examination of the abdomen under ether. The tumor could now be easily grasped through the thin parietes, and was found to be rugged in outline, about half the size of an orange. It showed the most remarkable mobility in all directions except downwards. It could be easily pushed under the last rib on the right side, and be there felt with the hand. It could be pushed almost into the same position on the left side, but with greater difficulty. It could not be made to descend. Nothing else abnormal was discoverable in the abdomen. After this examination, the patient was sick several times, but brought up no blood. The urine remained normal. From this examina-

tion, Mr. Baker strongly suspected cancer about the pylorus, though it was clear that there was much room for a difference of opinion as to the nature of the tumor, and he thought it might possibly turn out to be a floating kidney. One of his colleagues suspected a collection of biliary calculi in the gall-bladder. Every preparation was made for dealing with whatever kind of tumor should be found, and especially for excision of the pylorus, should it be necessary. The stomach was washed out twice on the day before operation, and again two hours before the latter, with warm water, introduced through a long flexible tube; and no food was given afterwards. With the most scrupulous care as to antiseptic, Mr. Baker operated on January 5, 1886, under the spray. An incision was made in the middle line, from just below the ensiform cartilage to the left side of the umbilicus. When the peritoneum was opened, the tumor presented at once to view. It was then easily diagnosed to be a mass of new growth, reaching from the anterior border of the pylorus about three inches to the left, and upwards towards the lesser curvature of the stomach. It was about the size of half an orange, flat externally underneath the serous covering of the stomach, and projecting into the narrow end of the latter. The posterior segment of the pylorus appeared sound to the touch. The tumor was perfectly non-adherent, but there were a few small hardened glands in the gastrocolic omentum. From the position of the growth and the presence of infiltrated glands, it was concluded that excision of the pylorus was contraindicated, and at once commenced the palliative operation of gastro-enterostomy, or the establishment of an artificial opening between the stomach and jejunum. After pushing the omentum, which was not voluminous, to the left, the first part of the jejunum was caught in the fingers, and a loop of it was drawn out of the incision. The middle of the anterior surface of the stomach was also drawn out, and was supported all round by warm carbolyzed sponges. Mr. Baker now passed a piece of the india-rubber tubing through the mesentery at each end of the loop of intestine; and, having emptied the portion of gut between by gentle pressure, drew the ends of the tubing tight enough to prevent access of the contents of the bowel into the loop to be operated on, and fixed each piece of tubing with a catch-forceps. The empty loop of gut was now laid upon the portion of the stomach to be

opened ; and a longitudinal fold of the latter, about an inch and a half from the great curvature, was pinched up between the finger and thumb of the left hand, together with the collapsed gut. An incision about an inch and a half long was now made in the fold of the stomach, and another corresponding in the approximated fold of the gut. These incisions only penetrated through the serous and muscular tunics, and left the mucous coat of both viscera intact for the present. Still holding the parts, as before, between finger and thumb, he now united the corresponding posterior edges of the wounds by a continuous suture, the needle entering and emerging in each case between mucous and muscular coats, and the threads crossing the cut edges of the muscular and serous coats. In this way, the serous surfaces were closely united from end to end before either viscus was opened. This row of stitches (which were about an eighth of an inch apart) was carried about a quarter of an inch beyond each end of the incision in the coats of the bowel. The moment had now come to open both the stomach and intestine completely ; and this was done with a stroke of a scissors through the mucous coat in each case, special sponges being ready to receive any fluid which might escape. A few drachms of *succus entericus* flowed from the bowel, little or nothing from the stomach-opening. After careful cleansing, the anterior borders of both openings were now united by a row of interrupted fine silk sutures, introduced according to Czerny's method. When this was completed, the two openings were securely closed ; but, as an extra precaution, the intestine was turned over, and the posterior suture was reinforced by a second row of interrupted sutures, placed about a quarter of an inch away from the first. The anterior row was then similarly reinforced by a row of continuous suture, taking up, as before, only the serous and muscular tunics. The elastic compressors were now removed from the gut. Lest there should be any "kinking" of the latter, as in one of Billroth's cases, Mr. Baker stitched its efferent portion to the stomach-wall, about three-quarters of an inch from the right extremity of the opening between the stomach and jejunum now established. The "toilet" of the peritoneum, replacement of the viscera, and closure of the external wound, completed the operation, which had lasted an hour and thirty-six minutes. The wound was dressed with salicylic wool. This mode of suturing the posterior edges of the opening

before the stomach is actually opened appears to be a new departure, and offers many advantages, which are obvious.

The patient bore the operation, on the whole, well, though towards the end the pulse became a little feeble. She was warm and comfortable when removed from the table. Peptonized enemata were ordered every six hours, and only ice by the mouth. There was no marked shock noticeable when she had recovered from the anæsthetic, but she complained of pain about the abdominal wound and to the left of it internally. She soon vomited some turbid fluid, and continued to do so for a couple of days, at intervals of four or five hours, bringing up from one to two ounces each time. This was not relieved much by hypodermic injections of morphine. As the vomiting went on, the fluid brought up became more and more turbid, and then became very fetid. It clearly contained matter regurgitated into the stomach from the jejunum, appearing most like pancreatic secretion very slightly stained with bile. The eructations, which were frequent, were also fetid. Thinking all this was due to simple gravitation of the contents of the jejunum through its dependent opening into the stomach, and as there were none of the signs of peritonitis, the patient was placed in the semi-recumbent position in bed on the third day ; at the same time, she was ordered one minim of creasote every hour in half an ounce of emulsion by the mouth. Whether as the result of the change of position, or of the use of creasote, the vomiting now ceased, and did not again return until the next morning, when she vomited for the last time.

The improvement was now uninterrupted ; the rectal temperature was usually below 100°. It is marked as 102° on the fourth day, but this is believed to be an error. Two hours later, it was 99.2°. On this day she was rather depressed, probably on account of menstruation having set in. The amount of brandy and beef-tea was doubled. On the fifth day she was given beef-tea by the mouth in ounce doses every hour, and on the sixth day an ounce of champagne every second hour and a tablespoonful of arrow-root. On the eleventh day she took some minced chicken, all of which was well digested. On the sixth day there were two natural stools, accompanied by a good deal of pain. On the thirteenth day Mr. Baker ordered half a drachm of confection of senna ; and on the fourteenth day she complained of a good deal of pain about the descending colon, which was relieved

by a high-reaching enema, which brought away a large quantity of *fæces*. Her general appearance began to improve after the first week, and the sunken look under the eyes to disappear. She also became cheerful, and expressed herself as very grateful for what had been done for her. She seemed so well on the seventeenth day after operation that she was allowed to sit up in a chair for half an hour, and enjoyed it greatly.

The stitches in the abdominal wall were all removed on the ninth day, and the wound was found to have united by first intention everywhere. It was still supported by broad strips of American rubber plaster in case of straining of any kind.

That the patient has been relieved by this operation, any one who has watched her can see plainly. That the greater rest secured to the diseased stomach by its new aperture of exit directly into the commencement of the jejunum may lead to a retardation in the development of the growth, there are some grounds for hoping. The food has not now to force itself past the cancerous and ever-narrowing pylorus, but can pass easily through the new opening, and so, perhaps, that ulceration of the surface of the growth, which leads to grave complications in many cases, may be staved off. As there is no interference here with the processes of digestion, the secretions of the liver and pancreas mixing as before with the food from the stomach, that slow process of starvation, accompanied by distention of the stomach and frequent vomiting, is prevented, which often renders these cases so painful and distressing to witness; the more so because, in many cases, the process is often very slow.

It is now more than a month since the operation, and still the patient continues well. She has suffered a little from constipation on one occasion, but has been relieved by enemata, and, to prevent this trouble recurring, is now taking small doses of laxatives. She sits up every day for some hours, after being confined to bed for more than five months. Her pulse is 78, her temperature normal, her bowels acting well, and altogether she is much improved and cheerful.

#### NOTES ON KAWA.

The highly interesting essay of L. LEWIN, the well-known Berlin pharmacologist, which was discussed in the February issue of the *GAZETTE*, has naturally aroused the curiosity of the profession to know more about this

powerful and hitherto practically unknown narcotic. In a recent meeting of the Berlin Medical Society, Lewin, being interviewed on the subject, communicated some novel data on this drug, which we abstract from the *Deutsche Medicinal Zeitung* of February 1, 1886.

The active principle of kawa contains no nitrogen. Lewin recently had an opportunity to test the effects of kawa on another physician, and was struck with their intensity and promptness. If six or seven division-marks of a Pravacz syringe are injected into the subcutaneous tissues of a man, sensibility becomes reduced to such an extent that a needle pushed into the subcutaneous tissues can be moved in every possible direction without meeting with a trace of sensibility. Later, Lewin undertook similar investigations on his own person, and found that in the entire neighborhood of the point of the injection, as far as the greenish resin could be seen shining through the tissues, sensation was utterly absent for five days. This anæsthesia was so complete during the mentioned period that local irritation elicited no response at all, and even strong induction-currents caused only a slight prickling sensation.

In conclusion of his remarks, Lewin stated that the drug may be of service, also, in another direction,—viz., as a means of disguising the taste of bitter or repulsive medicines; if the kawa-resin is applied to the tongue, and then quinine in substance or solution placed upon it, no trace of the bitter taste of the latter drug can be perceived.

#### THE ACTION OF CERTAIN DRUGS AND POISONS ON THE HEART OF THE FISH,

DR. T. WESLEY MILLS publishes in the *Canada Med. and Surg. Journ.*, March, 1886, an account of his investigations as to the action of various drugs on the heart of the fish. His experiments were made on the "toad-fish" (*batracus tau*). The drug was applied either in solution with a camel's-hair pencil, or simply dropped over the heart, the fish meanwhile being kept in a perfectly normal condition, bathing its gills in sea-water. That the effects witnessed were not due to indirect influence through the extrinsic nervous system of the fish was shown by isolating the heart, and treating it with the same drug or poison as the heart *in situ*. The results were always harmonious. The follow-

ing is a summary as to the conclusions to which his experiments led him:

*Summary of the results of the action of Atropine and Pilocarpine.*—1. Pilocarpine and atropine are antagonistic in action. The former is a cardiac depressor, tending to lower the excitability of the heart, render its action sluggish, and to stop it in diastole; the latter to improve a sluggish or weakened heart, and heighten the excitability of this organ under all circumstances. While pilocarpine tends to slow the rhythm, atropine quickens it, and increases the force of the beat. It manifests its action rapidly.

2. Atropine freely applied to the heart annihilates the possibility of arresting the heart reflexly.

Atropine applied to the conus arteriosus, arrested by a ligature between conus and ventricle, excites it to pulsation.

*Summary of the results of the action of Sodium Carbonate and Potassium Carbonate.*—Sod. carb. and pot. carb. are antagonistic in action on the fish's heart; the former quickens rhythm and diminishes diastolic relaxation, and heightens cardiac excitability, but is in this respect inferior to atropine. Potassium carbonate diminishes excitability, weakens the heart's action, and tends to arrest it in diastole. This agent seems to be a poison to the fish's heart.

*Lactic Acid.*—Lactic acid in five per cent. solution is a rapid poison, while in solution of one per cent. it depresses the heart, and gradually kills it in diastole.

*Digitalin, in somewhat less than One Per Cent. Solution.*—The action of digitalin may be stated thus:

1. Digitalin, when applied to a rapidly-beating heart, slows it.

2. Its invariable action, no matter what the condition of the heart, is to produce gradually increasing systolic contraction, the diastolic relaxation getting less and less till the heart is finally arrested in most pronounced systolic tetanus.

3. The peculiar action of the drug requires a short period before there is any decided manifestation of its effects; but when the latter do appear, they rapidly advance to a maximum.

4. It is not possible to stimulate a heart, brought to a stand-still by digitalin, to beat by mechanical means.

5. When the action is well pronounced, a large part of the time occupied in the systole of the ventricle is taken up in maintaining contraction when that is complete.

6. Digitalin neutralizes the action of various chemical agents, which, when applied to the heart, tend to cause undue diastolic relaxation (e.g., pot. carb.).

7. A ventricle brought to a stand-still by digitalin is unusually small, hard, and pale ("tonic" contraction).

*Nicotine in One Per Cent. Solution.*—1. The first effect of nicotine has generally been arrest of the heart in diastole for a variable, but brief, interval; when actual arrest has not taken place, the beat has been much weakened and the rhythm slowed.

2. This condition is usually followed by irregularity and an increased rhythm, without much damage to the force of the beat.

3. The different parts of the heart may not act with their usual proportionate force or frequency. There may be two or more beats of the auricle for one of the ventricle, etc. (incoordination.)

4. The fish's heart shows a remarkable power to recover entirely from the effects of nicotine.

*Veratrine in rather less than One Per Cent. Solution.*—It is much more difficult to define the action of veratrine than that of digitalin, though the eye readily appreciates differences. In general, the beat has that sluggish appearance seen after pilocarpine is used, but in other respects veratrine is very unlike that drug in action. One of the most marked effects is the tendency to throw the parts of the heart, and even parts of the ventricle, out of harmony with each other,—e.g., the central portion of the ventricle is sometimes seen to be more relaxed than the rest of it; the auricle often, after the action has lasted some time, gives several beats to one of the ventricle. It is also clear that the diastole takes place in a very sluggish way, quite unnatural to the fish's heart.

The effect on the diastole is certainly much greater than on the systole. In some phases of this action, at least, the systole is strengthened. In consequence of this effect on the diastole, the rhythm is slowed. We may put the salient points of its action thus:

The principal action of veratrine is on the diastole, which it renders more sluggish; the effect on the systole is slight, and possibly variable with the phase of action of the poison; as a consequence of its effect on the diastole, the rhythm is slowed. Want of harmony between the different parts of the heart and different fibres of the same part is liable to manifest itself.

*Chloroform (undiluted).*—Undiluted chloro-

form is a powerful cardiac depressor ; that its readiest effect is on the auricle proper ; that it can arrest the heart in diastole, but that this organ has considerable ability to recover from the effects of this agent.

*Acetate of Strychnine in One Per Cent. Solution.*—From a limited number of experiments with this poison, it appeared that it had the power to shorten the diastole and lengthen the systole, and slow the rhythm ; after arrest of the heart, it was still excitable by mechanical means.

It may be stated that in an area of the ventral wall of the ventricle, extending across it from the point of junction of the auricle, a behavior, under the use of drugs, is witnessed different from that of the rest of this part of the heart. Sometimes it seems more dilated ; at all events, it appears to be more susceptible to the influence of certain drugs and poisons (nicotine, chloroform, etc.) than the rest of the ventricle, but whether there is here difference in structure has not been determined. On hearts so sensitive as those found in the sharks and skates, drugs and poisons act with remarkable celerity.

#### URETHAN.

DR. A. S. MYRTLE writes to the *British Med. Journ.*, February 20, 1886, stating that since last October he has been using urethan in a variety of cases with satisfactory results.

He has used it in over fifty cases as a sedative and hypnotic, and his experience of its action encourages him to recommend the drug, believing that, in certain cases, it will prove of great value. The cases in which he prescribed it were of the usual run of everyday practice, where a sedative or hypnotic was required : general restlessness, sleeplessness, neuralgia, catarrh, certain forms of skin-affections with great irritation, also rheumatism and gout. Many of his patients had some peculiarity of constitution which prevented the use of opiates of the usual type ; and it is in this special class that he thinks urethan will prove of great value. One gentleman, who had suffered from insomnia for weeks, and who could not tolerate opium or chloral, took 15 grains at bedtime with the most perfect result. He wrote to Dr. Myrtle and said, "The sleep caused was most pleasant and refreshing. I awoke without a headache, with appetite for breakfast, and, what was equally agreeable, there was no interruption to any of my functions." Similar testi-

mony has been given by the majority of patients, who have taken full doses to produce sleep. In smaller doses, its action is less marked. Still, it is decidedly calmative and agreeable, causing no unpleasant effect, such as nausea, flatulence, constipation, or headache. It does not affect the nerve-centres of circulation or respiration, but spends itself on the cerebrum. It possesses, therefore, great advantages over the older and valuable sedatives, which have certain evil influences, especially in exceptional cases. Given in gout and rheumatism, in full doses, alone or in combination, it has the great advantage over morphine of not interfering with the action of the bowels or kidneys. Besides, it is not unpleasant to the taste. The only objection to it is its price, although that has been reduced fifty per cent. in the last three months.

#### THE TREATMENT OF STRANGULATED HERNIA BY IRRIGATIONS OF ETHER.

DR. BARTOSZ writes that for the last two years he has been applying with brilliant success irrigations of ether for the reduction of all cases of strangulated hernia which have come under his care. The irrigation is made after the method of Finkelstein (*Bull. Gén. de Thér.*, December 15, 1886), which consists in pouring on the tumor every half-hour a tablespoonful of ether, and allowing it slowly to evaporate. The hernia under such treatment disappears spontaneously, or may be readily reduced in obstinate cases by gentle taxis. In the seventeen cases in which the author states that this method served to reduce the hernia, strangulation had persisted in some only a few hours, while in others it is stated to have lasted already for several days, before the cases were subjected to treatment. The author further refers to a case of intestinal occlusion in a woman 60 years of age, in whom absolute constipation had existed for nine days, incessant fæcal vomiting and tympanites, thready pulse, etc., in whom, after a fruitless trial of all the known remedies, irrigation of ether on the entire abdominal surface in one and one-half hours caused a large evacuation of the bowels and the cure of the patient. This method of irrigation so employed by Bartosz may be replaced by driving the current of air from a bellows over the ether. Whatever, however, may be the means adopted, the ether acts by the refrigeration which its evaporation produces, and is therefore analogous to the application of ice, and

is consequently simply an improvement of the method whose value has long been recognized. We should think, however, that where the strangulation lasted for several days, as is stated by the author to have been the case in one of his instances of cure, even if the reduction of the strangulation should take place, there must be the greatest danger incurred in the return to the abdominal cavity of a knuckle of intestine which cannot but be gangrenous.

#### THE TREATMENT OF ACUTE INFANTILE BRONCHITIS.

At a recent meeting of the New York Academy of Medicine Dr. J. LEWIS SMITH read a paper with the above title (*Medical Record*, March 6, 1886). The subject was considered under two heads: (1) mild, and (2) severe bronchitis. He believed that simple bronchitis could be aborted, or rendered milder, by an emetic employed when the first symptoms appeared. For this purpose ipecac was probably the best. Measures designed to abort the disease, however, were not usually indicated when the patients were first seen; to be employed with success they must be adopted very early.

The treatment for mild, uncomplicated, primary bronchitis was very simple. A favorite mixture of the late Dr. Jackson, of Boston, consisted of equal parts of almond oil, syrup of squills, simple syrup, and mucilage of gum arabic. Of the mixtures in the Dispensary the *mistura glycyrrhizæ composita* was the best. The compound syrup of ipecac of the French Pharmacopœia was a most elegant mixture.

When the temperature was 102° F., and above, and the respiration correspondingly accelerated, he had been accustomed to use a mixture consisting of sweet spirits of nitre, syrup of ipecac, and syrup of balsam of tolu.

**Severe Bronchitis.**—When the inflammation involved the smaller bronchial tubes localized atelectasis was liable to occur, and also catarrhal pneumonia, which was one of the most dangerous diseases of infancy.

The indications for treatment in a severe case of bronchitis were to promote expectoration, to diminish inflammation, to strengthen the action of the heart, and prevent exhaustion.

In reference to cough there was safety in it, and he seldom added opium to any of his prescriptions which were designed to relieve cough. Although children did not expectorate, the bronchial tubes were as effectually

emptied when the sputum was swallowed. To facilitate expectoration two remedies had been used largely, namely, carbonate and muriate of ammonia; the latter was preferred in most cases, except in the advanced stages, when the former might be advantageous as a stimulant.

A favorite formula for the use of muriate of ammonia with him had been muriate of ammonia, one drachm; balsam of tolu, two ounces. When there was great dyspnoea and indications for clearing the bronchial tubes of mucus, this remedy should be administered every half-hour. Dr. Smith had not witnessed any marked benefit from the use of senega or squill. To get rid of large quantities of mucus an emetic was sometimes proper.

**To sustain the Patient and reduce the Fever.**—He had not noticed any marked reduction of the temperature by the use of quinine, but it seemed to him that it had been useful as a heart-tonic administered in small doses. For a child one year of age, half a grain to one grain. Antipyrine might be of service, but care should be exercised in its use. In a vigorous infant, suffering from bronchitis without or with only a very slight amount of pneumonia, it might be used. Digitalis as a heart-tonic was one of the best which could be employed. Alcoholic stimulation was necessary in severe cases; two or three drops of whiskey in water, for each year of age after three months, given hourly or every second hour.

**External Treatment.**—Leeching and vesication have been abandoned. Slight irritation of the surface affords relief, and for this purpose he had been accustomed to use a flaxseed-poultice, first rubbing the chest with camphorated oil in young children, and using a mixture of mustard and flaxseed, one to sixteen, in older children, enveloping the chest with the poultice and covering it with oil-silk. In those cases in which there was hurried respiration, accompanied by continued moaning, to cover the chest posteriorly and anteriorly with a poultice, and over the whole place an oil-silk jacket would afford marked relief.

In robust children the application of cold to the chest during the acute stage, as recommended by Henoch, of Berlin, might be of more service than poultices. For all infants under six months of age, however, poultices were preferable.

Change in position of the child he regarded as a most important element in the treatment,

laying the child first upon one side and then upon the other, and upon the back.

The chairman invited DR. A. JACOBI to open the discussion, who said that whenever Dr. Smith read a paper very little, if anything, remained to be said. There were some points which he would like to impress upon those present who had not seen a great amount of practice, and who would doubtless see more of these cases hereafter. One of the principal points to which allusion had been made, and of which he wished to speak, was the use of *opium* in these cases. We could not do well without opium in many of them, because there was so much irritation; but he would emphasize the necessity of giving as little as possible. If it was to be given at all, give a good-sized dose at night, for the purpose of securing a number of hours of sleep. He would express his conviction that in no small number of cases of capillary bronchitis and acute pneumonia in adults, the patients died in part of their disease, in part of the influence of opium. Certainly opium would suppress expectoration, and without expectoration bronchitis and pneumonia were almost invariably fatal.

There was one great expectorant which Dr. Smith had not mentioned, and that was *water*. Where was the expectoration to come from unless there was fluid in the body? It was all well enough to give muriate of ammonia and expect it to liquefy the expectoration; but the liquefaction could not take place without plenty of water, and the chief danger was that water was not supplied in sufficient quantities to young infants, older children being able to ask for it.

Another important point was the regulation of the temperature and moisture of the atmosphere in the room; this is especially important in all cases of so-called dry bronchitis.

With reference to the use of *digitalis*, he believed that two or three large doses in twenty-four hours were preferable to small doses frequently repeated. A child one year of age would take one grain of *digitalis* three times a day, for as many days as would be required, and the effect would be much better than if the remedy was used as it was usually employed.

Another exceedingly valuable expectorant was *camphor*, the effect of which was permanent, and it was more easily taken than carbonate of ammonia. A child one year of age might take one-quarter, one-half, or even one grain of camphor, rubbed up with glycerin

as often as every hour or every two hours, and in bad cases of bronchitis or pneumonia, where expectoration was wanted, he had not seen any expectorant which had served him a better purpose.

Turpentine, also, by inhalation, was an excellent expectorant. Put a tablespoonful or two tablespoonfuls of spirits of turpentine into the kettle of water which is kept in the room to moisten the atmosphere, and the air will be impregnated with the vapor of turpentine, which will greatly benefit the patient.

DR. JOHN C. PETERS was asked to continue the discussion, and said that one remedy, which was the best of all expectorants, and which allayed the cough, had not been mentioned, and that was potassium. The form in which he usually prescribed it was the liquor potassæ, one drachm to four ounces of water, and he very frequently used anise-seed water, which of itself was somewhat soothing. All of the alkalies, but more particularly potash, increased the ciliary movement of the bronchial epithelia, the only way in which expectoration was brought forward where it could be reached by cough. Besides, a solution of potassium would dissolve mucin, while simple water would not. He had almost abandoned the use of ipecac, except perhaps in small tonic doses. When there was great congestion and dyspnoea the administration of small doses of calomel, sufficiently large, however, to move the bowels, would relieve the heart and lungs, and render *digitalis* more active than it otherwise would be.

With reference to external treatment, he had used flannel chiefly, perhaps covering the chest with cotton. He thought that the frequent changing of poultices exposed the infant too much.

With reference to change of position, he had been in the habit of placing the child on the face, and had found it very beneficial.

He never used quinine as an antipyretic, but thought it beneficial in preventing the migration of leucocytes.

DR. JOSEPH E. WINTERS said that while, perhaps, acute bronchitis could not be aborted, the inflammation certainly could be minimized. During the time when the congestion was limited to the bronchial artery, remedies which reduced the force and frequency of the heart's action would reduce the inflammation, and for this purpose he employed veratrum viride, already mentioned by Dr. Ripley, or aconite; as a reliable article of veratrum viride was somewhat difficult to obtain, he frequently used the latter agent. This ex-

pectation, however, was realized only in cases of acute primary bronchitis.

After this his method of treatment was to use derivatives, and then mild cathartics, consisting chiefly of alkaline mixtures.

The second indication was to prevent accumulation of catarrhal secretion, as here occurred all the deaths. For the prevention of the accumulation of this secretion he used stimulating expectorants, and they varied according as to whether the expectoration was thin or viscid. In this condition cough also became remedial. During the catarrhal stage he combined camphor with other agents in a sufficiently concentrated form to excite a cough, which would, in part, be voluntary. Besides, he applied stimulating liniments to the surface of the chest, which would provoke deep inspiration. For this reason he thought that large poultices were dangerous, and that putting a pound of flaxseed, mixed with water, upon the chest of a child one year of age, would materially interfere with respiration. He preferred the oil-silk jacket, or, perhaps, spongiopylin, with cotton batting and oil-silk. The oil-silk was generally sufficient, with the use of a stimulating liniment, applied by putting the hand under the jacket, without exposing the chest of the child at all. He always insisted upon the following order in most of these cases: First, make the external application, then administer the expectorant, which would excite a cough, and then administer an emetic, and do all this at bedtime.

Opium became a dangerous remedy in young children, and he thought chloral did equally as well. When the secretion was watery and excessive, camphorated tincture of opium might diminish cough and secure rest, but it was not often indicated.

As to whether capillary bronchitis existed independently of broncho-pneumonia, he had his doubts, because when capillary bronchitis was found at autopsy it was associated with more or less of broncho-pneumonia.

DR. H. D. CHAPIN made special reference to the use of bromide of sodium, which he had used with good results. The use of opium had been pretty well condemned by the speakers by whom he had been preceded; and even in the doses recommended he had seen, it seemed to him, unfortunate results due to its use. In rachitic children he had noticed a more rapid and a more marked narcotic action produced by opium than in otherwise healthy children. In one case he felt quite certain that the brown mixture, regarded as perfectly safe in ordinary cases,

nearly caused the death of his patient. For some time, therefore, he had used the bromide of sodium, and although it did not act rapidly, yet, by giving it continuously, it produced a sedative effect, which had seemed to him to be safe and beneficial. He would be more afraid to use chloral than opium.

With reference to cases of mild bronchitis, he thought one of the best remedies was to put the child to bed at the outset, and when this was done the large majority of children would get well without special treatment.

DR. J. H. FRUITNIGHT spoke of the use of iodide of potassium in the second stage of the disease, especially when the secretion was viscid, administered in doses of one-fourth to two grains, according to the age of the child. He favored the use of oil of turpentine combined with balsam of fir.

#### ON PARTHENIUM HYSTEROPHORUS.

DR. ULRICI publishes a brief note on this plant, a native of Cuba, in the *Deutsche Medicinische Wochenschrift* of February 8, 1886, from which we abstract the salient points. The plant is in its home called escoba amarga, or confitilla, and has been in use with the natives as a febrifuge since time immemorial. It contains an alkaloid,—parthenine,—and, besides, four other alkaloids, and the non-crystallizable parthenic acid. Parthenine is crystallizable, and represents the active principle of the plant. One and a half grains of this alkaloid brought on the tongue in a watery solution produces a quickly-disappearing bitter taste and an increased salivation. One-fifth to one grain causes a sensation of warmth in the stomach and an increase of the digestive power. In doses of 3 grains the alkaloid quickens, and in 15-grain doses slows, cardiac action. The arterial pressure and respiratory frequency sink likewise after larger doses. The temperature of a healthy person is not affected by doses below 7 grains; 50 grains given in two doses cause a small reduction of temperature. The urinary secretion remains unaltered under the influence of the drug. Several trials with parthenine go to show that this alkaloid possesses some anti-neuralgic value.

#### THE TREATMENT OF PAINFUL FISSURE OF THE ANUS WITHOUT OPERATION.

The two plans of treatment generally recommended as the only reliable ones for the treatment of anal fissure are incision or

stretching of the sphincter muscle. As a rule, perhaps, stretching may be preferred, as it causes no external wound, and therefore does not render the patient liable to septic poisoning. MR. A. D. MACGREGOR (*Brit. Med. Journ.*, February 27, 1886) treats such fissures without any operative interference at all, and he claims that his success is such as to warrant a continuance of his method. His plan is first to order a full dose of castor oil with some rhubarb; when this has well operated the bowel is to be washed out with an enema of Condyl's fluid. After passing the speculum, the fissure is then to be painted with a solution of chloride of zinc, twenty grains to the ounce, and a piece of lint smeared with boric ointment, then introduced, the contraction of the sphincter serving to keep the lint in contact with the sore. The bowels are kept closed by opium, and liquid food only allowed. The subsequent treatment consists in the use of powdered boric acid half a drachm and violet powder one ounce, sprinkled freely on lint, and introduced into the anus to dry up any discharge. Mr. Macgregor states that one application of chloride of zinc in his experience has always proved sufficient, and only causes some smarting and uneasiness.

#### RESPIRATORY THERAPEUTICS.

There is an evident tendency, especially among continental physicians, to react against the system of endeavoring to treat affections of the respiratory organs exclusively by means of medicinal agents, which act on the system at large. It is beginning to be recognized that many, if not most, of these affections are local in their origin and in their course, until indeed the maintenance of life itself is menaced by the acquired incapacity of one important organ. The sooner this view of the pathology of lung-diseases is recognized, the better will it be for the comfort, if not for the cure, of the patient. We may even go a step further, and maintain that, even in lung-affections where the constitutional condition is not without importance, either in their etiology or in their course, much relief may be obtained and improvement effected by a judicious resort to the means which modern therapeutic research and ingenuity have placed at our command.

The truth of what we have advanced is already partially admitted by the profession and by the public, in the limited applications of

remedies in the form of vapors or sprays; but this method of treatment merits, and will doubtless obtain, a more thorough employment as a knowledge of its advantages becomes more general. Mechanical difficulties have long stood in the way of the more extensive adoption of the method of direct application to the irritated or inflamed mucous membrane of the respiratory tract; but this can now no longer be alleged as a sufficient reason for its non-employment. That it involves more trouble, and especially more direct supervision on the part of the medical attendant, is not to be denied; but that this increased trouble should be deemed an adequate objection to its administration, can scarcely be allowed. A recent contribution by Dr. Murrell on the subject of pure terebene as an inhalation, shows that the value of such applications is gradually becoming appreciated in this country.

The resources of this branch of therapeutics are more extensive than one is apt to imagine. Not only can constitutional effects be readily and promptly induced when desired, but drugs can be inhaled in the form of a vapor, or in solution as a spray, or in the solid form as an impalpable powder. By these means any desired effect can be produced, anodyne or expectorant, soothing or astringent, or antiseptic; all can readily be directed immediately on to the affected surface, and their beneficial results promptly and certainly obtained. Nor is this all. Thermic therapeutics have been resorted to ever since the days of Hippocrates as an adjunct to the more ordinary methods. By means of variations in the temperature of the inspired air, the characteristic effects frequently utilized in what we may call external medication may be made to exercise their influence here, and there can be no reason to doubt their efficacy in this case as elsewhere. Then, again, modifications in the composition of the inspired air may be and have been turned to account. The inhalation of a more highly oxygenated atmosphere, or of one more rich in that active form of oxygen, ozone, has during the present century been largely experimented with; and, even if the results have not come up to the somewhat extravagant hopes entertained when Priestley first discovered and promulgated the novel and curious qualities of this gas, enough has been observed and recorded of its influence to justify one in hoping for its further employment in the future.

The most modern addition to this department of therapeutics is perhaps the mechani-

cal treatment of certain affections of the respiratory tract by means of alterations in the pressure of the air. The various apparatus, designed with this object in view, comprise quite an arsenal, from the complicated inventions of Finkler and Koch to the simple accordion-bellows of Fränkel. On a more elaborate plan, the pneumatic chambers are available, and have been in operation for some years with, it is alleged, eminently beneficial results in a restricted class of cases. We are all of us familiar with the advantages attending a change of air with certain patients and in certain maladies; and it cannot be doubted that much of the good so obtained is attributable partly to the change in atmospheric pressure, in combination with variations in the hygroscopic and electric properties of the respired air. What has been done of late has been with a view of conducting the treatment on a scientific basis, whereby, with careful observation, the credit due to the various factors of pressure, temperature, and composition can be more accurately determined, and long, expensive, and unnecessary voyages rendered to a large extent superfluous.

The methods of inspiring compressed air or expiring into compressed air have given especially good results in certain cases. The effect of the former is obviously to raise the tension of the air in the lungs, thereby facilitating and accelerating the interchange of gases. The expansion of the thorax is perceptibly increased even in a healthy subject; and, where the lung is bound down by false membrane, or is otherwise prevented from complete inflation, the increase in its vital capacity is as rapid as it is marked. Patients suffering from asthma, chronic bronchitis, bronchorrhœa, or emphysema, often experience great relief from even a single application. The increase of pressure need not and ought not to be very great. From one-sixtieth to one-thirtieth of an atmosphere is that most generally employed.

It is to be regretted that in this country no facilities exist for systematic treatment of this kind, beyond one or two special institutions; and in this respect we are much behind our continental brethren. In Germany and France the treatment is in full swing, and is said to be attended with much benefit in those cases where its employment is indicated. In a country like ours, where bronchial affections form a large and distressing proportion of our troubles, it is singularly inappropriate that fresh means and appliances for treat-

ment should be left comparatively untried.—*Brit. Med. Journ.*, March 6, 1886.

#### MANAGEMENT OF BREECH PRESENTATIONS.

At a recent meeting of the New York Academy of Medicine DR. ROBERT A. MURRAY read a paper with the above title (*N. Y. Med. Journ.*, March 13, 1886), which dealt principally with the measures necessary to be taken to deliver in breech cases and to diminish the percentage of mortality. The importance of an effort in this direction was apparent from the fact that the statistics quoted from authorities gave a mortality in breech presentations of about one in eight and a half cases. Among the causes of this class of presentations were a contracted pelvis, an excessive amount of liquor amnii, violent movements, and a peculiar formation of the lower segment of the uterus. It was also remarkable what a large proportion of the cases occurred in premature labor and multiple pregnancy. The statistics of Simpson went to show how frequently, the child being dead, the loss of tonicity of the spine and the presence of flaccidity in the tissues caused malpresentations; those tables demonstrated that there was a constant tendency after the sixth month of pregnancy for the head to present.

In a case of breech presentation in which the mother's pelvis was of full size and regular form, and the child of moderate proportions, labor would probably be accomplished without particular difficulty, and the obstetrician had only to wait. If, however, the indications were that the labor would be difficult, if the pelvic cavity was not roomy, or the child of large proportions, version, if it was to be performed, should be done early, before the rupture of the bag of waters. If the case was allowed to progress, no obstruction being met with, the critical moment for the child would be just after the birth of the trunk and lower extremities, for now the cord was in danger of becoming compressed between the unyielding head and the pelvic wall. The cord should be pulled down and placed next the sacro-iliac synchondrosis by the side of the child's head, where it would be least likely to become compressed. The contractions of the uterus might be followed up by the hand, and flexion of the head might be aided by raising the trunk of the child. But in cases in which the limbs were extended upward over the front of the child, so that the toes were near the face, the breech was not nearly so large as the child's

head, and, being readily moulded, entered the pelvic cavity; the entire foetus then presented, as Barnes had well described, the form of a wedge with the base upward. Now, if traction was made by means of hooks, fillet, or forceps, and unsuccessfully, as it was likely to be, the apex would be dragged into the pelvis, and, the cavity becoming more tightly filled, compression of the cord would be increased, and the uterus rendered more irritable, and here the only measure for the safety of the mother and child was to bring down a foot. The use of the blunt hook to do this was difficult, as it was apt to slip and injure the soft parts or cause fracture of the thigh; consequently, if the child was living, it should not be resorted to. The fillet, if it could be guided over the limb, might cut the tissues or prove too weak to overcome the difficulty. The obstetric forceps had been recommended in these cases, but it was condemned by most authorities. It was only adapted for use on the head. The performance of cephalic version, as recommended by Spiegelberg, would be possible only before rupture of the bag of waters and before the breech became wedged.

The clear indication in such a case was to break up or decompose the obstructing wedge, which was to be done by bringing down one foot. The position of the breech in relation to the pelvis having been determined by ordinary diagnostic points, the hand was to be passed in front of the breech where the foot lay, and one foot seized by the instep and brought down; then the breech would probably soon descend. The cord would be better protected than if both feet were brought down. The foot nearest the pubes was most easily drawn down. If the case was not otherwise complicated, the labor would now go on naturally. If the breech filled the brim, or was forced into the pelvic cavity, little space would be left for the operator's hand, and under these circumstances the hand would have to be passed up to the fundus uteri in order to grasp the foot. That hand should be introduced whose palm would touch the abdomen of the child when introduced. When the foot was reached, preferably the anterior one, it was to be seized by the instep and drawn down out of the vulva. It was essential to get hold of the foot; taking hold of the knee, or hooking the thigh in the groin, would be of no use. During the operation the uterus should be supported by the other hand or by an assistant. If inertia uteri should now exist, we should still have at-

tained, by our hold on the foot, security for further progress of the case.

The operation of extraction by the breech might be divided into: 1. Drawing the trunk through the pelvis. 2. Liberation of the arms. 3. Extraction of the head. Traction on the leg should be carefully made, in drawing the trunk down, coincidently with the pains. The trunk should be drawn downward and backward in the axis of the brim, external pressure being made by an assistant, the traction being kept up until the breech was fairly in the pelvic cavity. After the extraction of the breech, the cord should be carefully looked after. Liberation of the arms might become necessary if the pelvis was at all contracted, or if traction upon the trunk had been too rapid, or had not been accompanied by external pressure on the uterus.

The head being at the brim, Smellie's method might be employed in the manner recommended by Schröder, or the method of Scanzoni. In all cases of breech presentation the forceps should be at hand ready for application to the head if it should be necessary. Particular care should be taken during its introduction not to lacerate the cervix. Passing a catheter up into the mouth of the child at this stage would frequently save life.

The subject of the management of breech presentations had been brought to the author's mind forcibly during the past year from the number of cases which he had seen in consultation, in nearly all of which he had found difficulty arising from flexion of the legs on the abdomen, diminishing the size of the breech to a certain extent, and at the same time forming a wedge that became more tightly impacted as the child descended. In all of these cases unsuccessful efforts had been made to extract before he was called, and he was impressed with the advantage of introducing the hand and bringing down the foot over other methods, such as the use of the forceps, the blunt hook, the fillet, etc.

*ARTIFICIAL ANÆSTHESIA WITHOUT  
SLEEP AND RETENTION OF IN-  
TELLIGENCE, MOTION, AND  
SENSIBILITY.*

In the *Centralblatt für Chirurgie* of February 20, 1886, we find an interesting account by BROWN-SÉQUARD of a novel form of anæsthesia, which he has established by experiments on animals and on man. The author published some years ago a remarkable observation of his, viz., that by irritation of the

laryngeal mucous membrane he could eliminate to a more or less degree all sensation of pain from all parts of the body. This remarkable effect is brought about by an inhibition exerted by the superior laryngeal nerves upon the nerve-centres, and can be limited almost exactly to one-half of the body. Since that time Brown-Séquard instituted numerous experiments on man and animals. In nine monkeys and forty-three dogs the experimenter could produce analgesia without sleep, after the opening of the trachea, by means of carbolic acid, chloroform, or sub-respiratory intramucous injections of cocaine. Especially striking was the effect of an irritation of the mucous membrane of the larynx and neighboring parts, such as the trachea and pneumogastric nerve above the branching off of the superior laryngeal nerve. Other modes of producing an irritation on the mentioned region were also tried, but proved less efficient. Among these the author mentions the following: galvanization of the superior laryngeal nerve or of the larynx, cauterization of the laryngeal mucous membrane by nitrate of silver, hydrate of chloral or other caustics, kneading of the larynx, introduction of a catheter into the laryngeal channel, and division of the trachea or of the integument of the neck in front and on the sides. After the cutting of the integument of the neck the experimenter did not, as a rule, observe general anæsthesia, but noted the same to radiate from the wound over the entire neck down to the ends of the shoulder-blades. This fact suggested to Brown-Séquard the possibility of successfully combating the epileptiform affections of various animals originating in this zone.

The wounds themselves remain insensible up to the time of cicatrization, and in the animals experimented upon, large nerve-trunks can be cut and deep cauterization or galvanization be performed without eliciting any expression of pain. Still, in the majority of cases the analgesia produced in the stated manner extended only over the superficial parts of the body, though its duration was generally from fifteen to twenty hours. The sense of touch and the muscular power remained likewise intact.

It is clear that this method of causing anæsthesia can find but a limited and imperfect application in man. Brown-Séquard indeed made some very interesting experiments in this field which may possibly, at some future time, lead to more definite and available results. He exposed the person to be experimented

upon for two-thirds or three-fourths of an inspiration to pure air and for the remaining one-third or one-fourth to carbonic acid gas, which, however, was, at once again expired. Neither this gas nor chloroform should enter the lungs, lest the analgesic influence of the superior laryngeal nerves upon the nerve-centres be removed. These inhalations had to be continued in man for twenty minutes in order to obtain the three peculiarities of this kind of narcosis, viz.: 1, A complete analgesia of the skin, lasting for forty hours; 2, a cessation of various kinds of pains for the period of two days; 3, a perfect absence of the sensation of fatigue.

Brown-Séquard concludes that it is possible by an irritation of the laryngeal mucous membrane in man and animals to decrease or even abolish the sensation of pain without interference with the intelligence, the senses, and the voluntary movement.

#### THE RELATIONSHIP OF THE FORMATION OF UREA AND URIC ACID TO THE SECRETION OF BILE.

DR. D. NOEL PATON publishes in the *Brit. Med. Journ.* for March 6, 1886, the following summary of an elaborate series of experiments which he made in the physiological laboratory of the University of Edinburgh in order to determine the relationship as to the formation of urea and of uric acid to the secretion of bile.

1. *Salicylate of Sodium*.—(A) *In man*. In dose of 0.106 gramme per kilogramme, salicylate of sodium causes no change in the amount of water passed, a slight increase in the urea, and a very marked diminution in the uric acid excreted. This last change is by far the most manifest; in one experiment the diminution was as great as 64 per cent. (B) *In dogs*. In doses of from 0.45 gramme to 0.6 gramme per kilogramme, salicylate of sodium caused a marked diminution in the water passed, a rise in the urea, and a great diminution in the uric acid excreted.

2. *Benzoate of Sodium*, in doses of from 0.51 to 0.58 gramme per kilogramme, causes little or no change in the amount of water. The urea is greatly increased, and the uric acid is diminished, though not so markedly as with salicylate of sodium.

3. *Colchicum*, in doses of 0.02 to 0.037 gramme per kilogramme of the acetic extract (*B.P.*), causes a very marked increase in the urea and uric acid. When the doses are

small, the water is also increased ; but, with large doses, the water secreted may actually fall, while neither the urea nor the uric acid are so markedly increased as with smaller doses.

4. *Perchloride of Mercury*, in doses of from 0.0015 to 0.0075 gramme per kilogramme, causes an increase in the excretion of water, urea, and uric acid.

5. *Euonymin*, in doses of from 0.04 to 0.10 gramme per kilogramme, causes a slight increase in the water excreted, a very marked increase in the urea and uric acid. In larger doses, 0.16 gramme per kilogramme, it causes purging, with no diminution in the water passed by the kidneys, but without the marked rise in the urea excreted.

It is thus seen that, in dogs in a condition of nitrogenous balance, stimulation of the flow of bile by means of these drugs is accompanied by an increased production of urea. That an increased production, and not merely an increased excretion of urea, occurs, is clearly shown by the fact that, after the administration of the drug was stopped, the amount of urea merely returned to the normal, and did not manifest a fall corresponding to the initial rise.

Dr. Paton therefore concludes that the formation of urea in the liver bears a very direct relationship to the secretion of bile by that organ. On the nature of this relationship he has not touched in the present paper ; but at an early date he hopes to give the results of a series of experiments upon this subject.

To the physician, the results of these observations must have considerable interest, especially of those which, dealing with the influence of salicylates and benzoates upon the excretion of uric acid, afford a key to their mode of action in gout. No less interesting is the demonstration of the fact that colchicum increases, and does not diminish, the production of uric acid.

#### *SALICYLATE OF SODIUM IN IRITIS.*

At the meeting of the Baltimore Academy of Medicine, held February 16, 1886, DR. SAMUEL THEOBALD (*Maryland Med. Journ.*, March 6, 1886) referred to some interesting results he had recently obtained by the use of salicylate of sodium in iritis, occurring in patients with a history of inflammatory rheumatism.

Three weeks ago a young lady had called to see him. She had a most intense plastic iritis, pupil perfectly immovable. She had

only perception of light, and could not count fingers at the ordinary distance. She was ordered sodium salicylate, and in a few days she obtained much relief. This salt was then withdrawn and iodide of iron ordered. She did well until the end of several days, when she reappeared, complaining of the same trouble, which increased in intensity until, at the end of two days, she was in the same condition as originally. The salicylate was repeated, as well as the atropine drops locally, and mercurial inunctions to temples. Cathartics were ordered, and in *two days* she was so very much improved that vision equalled  $\frac{3}{4}$ , and the media sufficiently clear to permit satisfactory inspection of the optic disk.

She had had some glaucomatous tension, but this did not prevent his ordering atropine, nor interfere with the physiological and therapeutical action of the drug.

#### *A NEW METHOD FOR ANÆSTHETIZING THE UNINJURED SKIN WITH COCAINE.*

DR. WAGNER, at the meeting of the Society of Physicians at Vienna, held February 5, 1886, described a method by which the uninjured epidermis might be rendered anæsthetic through the application of cocaine. For this purpose he made use of the property of a galvanic current discovered by Dr. Haertner, in consequence of which fluids move from the positive to the negative pole. If the positive electrode is dipped in a cocaine solution, and placed upon the skin, and the negative pole placed a short distance from it, and a current allowed to pass, the skin lying between these two points of application of the electrode becomes anæsthetic. Wagner made a number of experiments to determine the value of this method to surgical practice in the clinic of Prof. Billroth, and found that by the means of this such anæsthesia as would prevent the appreciation of incisions of the skin was readily attainable.—*Wien. Med. Blatt.*, February 11, 1886.

#### *THE RADICAL CURE OF HYDROCELE.*

At a recent meeting of the Academy of Medicine in Ireland, MR. MCARDLE read a paper on the radical cure of hydrocele. After describing the methods of Volkmann, Julliard, and Bergmann, he read the notes of three cases illustrating the method of incision (*Medical Press*, March 10, 1886). He brought forward specimens to show the ease with which the tunica vaginalis could be removed in the

operation for excision. He then compared the methods of injection and dissection chiefly as regards—1st, the relative difficulties of the operative procedures; 2d, the dangers attending each; 3d, the length of time required for cure; and, 4th, the chances of return after each method. In reference to the third point he called attention to the following as the dates of healing. After

Injection.	Incision.	Excision.
Billroth.....9th	Volkman. 8th-10th	Julliard..... 10th
Stolz.....10th	Küster..... 14th	Bergmann. 11-12th
Weiss.....8-9th	Lister..... 17th	

The chances of recurrence in various methods he stated as follows:

Cases.	Injection.	Recurrences.
315		41
	Incision.	
238		5
	Excision.	
72		0

The percentage of recurrences after injection of different substances seemed to be very much the same. After iodine, fifteen per cent.; chloral hydrate, thirteen per cent.; perchloride of iron, eleven per cent.; carbolic acid, ten per cent.; and chloroform, ten per cent. Mr. McArdle recommended the dissection method in—1st, multilocular hydrocele; 2d, hydrocele connected with tubercular testis; 3d, cases complicated by mucoid transformation of the cellular tissue of the scrotum; 4th, cases where injection of ordinary hydrocele failed more than once; and, 5th, those cases of hydrocele in which the tunica vaginalis becomes greatly thickened, coated with chalky deposit, or filled with foreign bodies.

In the discussion which followed, Mr. STOKES said he could not, in his own practice, recall a single instance of failure in the radical cure of hydrocele by what Mr. McArdle termed the old method of injection, although, however, some of his cases had been injected more than once. In none of the cases was there any serious trouble, such as fever, sloughing of the scrotum, erysipelas, etc., therefore he was not supposed to alter his method of treatment for one more hazardous. He had seen Volkmann's treatment by incision, and one of the most important points connected with it had not been mentioned,—namely, that, having incised the tunica vaginalis, and attached the edges with great accuracy to the edges of the skin by continuous sutures, a series of deep sutures were applied to keep the surfaces in apposition. He had seen serious consequences follow the operation,—for instance,

retention of urine and fever. Another objection was the difficulty of keeping on antiseptic dressings, and there was also that of preventing the sutures ulcerating through the tissues of the scrotum. While there were all these difficulties and dangers attending the treatment proposed, it was obvious that the old and simple method of using some of the preparations of iodine was the one that in the majority of cases was to be preferred.

MR. BARTON said the question was one of choice between the operations which admittedly had certain risks and the well-established procedure which was without any serious risk. He was therefore gratified that Mr. McArdle had recommended those operations for the treatment of hydrocele only in difficult cases which had resisted injection. That limited materially the scope of the recommendation. His own experience was, like Mr. Stokes's, that he could not recollect a single case in which the injection plan had failed to produce a cure, nor one in which it had produced dangerous symptoms. There was occasionally delay experienced, but ultimately, with care, those cases were also successful. Therefore he did not see any necessity for the operations recommended. He could, however, imagine complicated cases in which some other means than injection must be tried; but such cases were very few, having regard to the fact that surgeons of experience had not met any. On the other hand, the treatment of injection by iodine was the outcome of many years' surgical experience.

#### THE TREATMENT OF CERTAIN FORMS OF TYPHOID FEVER BY INJECTION OF ERGOTIN.

DR. EMILE DE MANGE has recently published a paper on a mode of treatment which he claims renders great service in the treatment of certain forms of typhoid fever (*Journ. de Méd.*, January, 1886). Often, when a typhoid fever patient has reached the end of the second week, the temperature will oscillate around 40° C., with scarcely any morning remission, pronounced ataxia will be present with delirium and agitation. The pulse, above 120°, becomes small, compressible, and weak; the movements of the heart are quick and weak, and the heart-sounds, especially the first, are feeble; pulmonary hypostasis is marked; the extremities become cyanosed, livid, and cold; irregularity of the pulse becomes more and more marked, and syncope and impending death is evident. In such a case De Mange

first employed the subcutaneous injection of 15 grains of ergotin. Ten minutes later the pulse, which was thready and scarcely perceptible, had increased considerably in strength and volume. A second injection was made six hours later, and again during the night following, when it appeared that the pulse was a second time becoming feeble. From this moment convalescence set in, and, although complicated by an intercurrent pleurisy, terminated in a complete cure. De Mange explains the influence of ergotin in such a case by claiming that the symptoms on the side of the vascular apparatus are due to some disturbed cardiac and vascular innervation, and therefore ergot, by increasing the arterial tension, is indicated. He, therefore, thinks that ergotin should be administered in what he terms the cardiac form of typhoid fever, or, in other words, cases characterized by excessive acceleration of the pulse and weakening of the arterial tension.

---

*A CASE OF THORACIC ANEURISM TREATED  
BY THE INTRODUCTION OF STEEL  
WIRE INTO THE SAC.*

At the meeting of the Royal Medical and Chirurgical Society held February 23, 1886, DR. W. CAYLEY (*Brit. Med. Journ.*, February 27, 1886) read an account of a man who was admitted into the Middlesex Hospital who had suffered from symptoms of a thoracic aneurism since November, 1884, but it was not until five days before his admission that a pulsating tumor made its appearance at the root of the neck, rising about three inches into the neck behind the right sterno-clavicular articulation.

The patient was at first treated according to Tufnell's method, and given large doses of iodide of potassium. The tumor continued to increase in size, and it was evident that it must either soon burst externally or extravasate among the tissues of the neck. On June 24, Mr. Hulke introduced into the sac, through a fine canula, forty feet of steel wire. This caused no constitutional disturbance or local pain, and this portion of the aneurism became completely consolidated. Towards the middle of August, signs of the extension of the intra-thoracic portion of the aneurism—increasing dyspnoea and severe paroxysmal cough—became more marked, and there was an increase of pulsation behind the sternum and towards the left sterno-clavicular articulation. As it was evident that the aneurism must soon prove fatal from pressure on the trachea, it was de-

termined to endeavor to consolidate the part of the sac producing this pressure. Accordingly, on September 10, Mr. Gould, in the absence of Mr. Hulke, introduced a canula just above the left sterno-clavicular articulation, directing the instrument obliquely towards the middle line, and introduced thirty-four feet nine inches of wire. No constitutional disturbance followed, but no relief was given to the symptoms, and the patient died in a paroxysm of dyspnoea on September 19. On post-mortem examination, a large aneurism was found springing from the ascending part of the arch, and communicating with the vessel by a very large orifice; the whole of the upper portion was completely filled by a clot, embedded in which was the wire. The wall of the aneurismal sac, where it projected into the neck, consisted only of a little condensed connective tissue. The lower portion of the sac, near its origin from the aorta, caused compression and flattening of the trachea just above its bifurcation. The first operation produced the desired result in preventing the imminent rupture of the aneurism. The size and connections of the sac rendered the second operation ineffectual.

---

*THE "DRY TREATMENT" FOR UTERINE  
DISORDERS.*

In a paper read before the St. Louis Obstetrical and Gynæcological Society, DR. GEORGE J. ENGELMANN brings forward what he terms a new departure in uterine therapeutics. Preliminary to a description of his own methods, Dr. Engelmann gives an interesting sketch, showing the national peculiarities of gynæcologists, so far as topical therapeutics is concerned. "In Germany," he says, for instance, "at one time the washing of cervix and vagina with strong solutions was an almost universal practice; in many clinics it was customary, whether other treatment was applied or not, to wash cervix and vagina with strong solutions of sulphate of copper, or carbolic acid, through the Ferguson speculum. In France—I am only speaking of methods which are not used here—they use the cautery, and medicated supports to the uterus; the thermo-cautery also is a specialty in French gynæcology; a common usage is to apply a remedy in a small semicircular bag made of muslin or mosquito-bar, which at the same time serves as a support for the uterus. This country is peculiar in its use of nitrate of silver and iodine, though in England it is used in a similar way, but by no means as freely and as commonly as here."

Dr. Engelmann's new departure consists essentially in the use of medicated absorbent cottons, with or without the addition of a powder-blower or gelatin pencils. The medicated tampons have the advantage, we are told, of giving support to the uterus, of acting continuously and evenly, and of being cleanly. The tampons may also be made of jute, and perhaps the best combination is a medicated jute tampon covered with a layer of the softer cotton. The powders used are those of alum, bismuth, tannin, salicylic acid, iodoform, and zinc. Next after these in value are the gelatin or iodoform pencils. The cotton or jute used is medicated with iron, boracic acid, alum, tannin, iodine, and other substances.

By the use of the powders or pencils and tampons, in endocervicitis, erosions, and other chronic uterine troubles the profuse discharge is often checked very promptly, and a healing process set in action. Dr. Engelmann does not recommend the glycerin tampons which are considerably used in New York. His "new treatment," though a good one, is not, we venture to say, very new; something very much like it—*i.e.*, the use of powder and cotton tampons—was, we believe, at one time quite the routine practice in Vienna. In New York also cotton tampons medicated with alum and other powders have been used for six or more years.—*Medical Record*, March 20, 1886.

#### ON RESORCIN IN THE TREATMENT OF ECZEMA.

There are few diseases for which such a number of various methods of treatment have been proposed as for eczema. The multitude of remedies praised as a cure for diseases of the skin is often embarrassing to the physician, who expects to find the same simplicity in the therapeutics of skin-affections as is established in the general practice. In the absence of any universally recognized treatment of eczema, the proposition of any remedy whose physiological and chemico-physical properties are suitable for the affection may claim our attention.

In the *Fortschrift* of January 5, 1886, Dr. A. Wyss publishes an essay intended to demonstrate the efficacy of resorcin in eczema. We abstract from this paper the main points of interest.

In the treatment of eczema two principal questions present themselves for consideration: 1, Is the eczema acute or chronic; and, 2, with which period of the affection have we to deal? These questions ought not be an-

swered only for each patient particularly, but also for each localization of eczema on the same individual. On one surface of the body, the eczema may have attained its period of desquamation, while on another the affection may still be in its papular phase. The remedies employed in chronic eczema would often have a disastrous effect if applied in acute eczema. In one word, strict individualization is an indispensable requisite with every case of eczema.

In the acute form of eczema the employment of directly healing applications is useless and better avoided. "To do nothing," says Rayer, "is the best treatment of acute eczema." All irritant measures, such as washes of cold water, are especially detrimental. Subjective symptoms, such as pain and itching, may of course receive a special medication by powders or alcoholic lotions, with the additions of camphor, phenic acid, chloral, menthol, and cocaine.

If there is any discharge, desiccant powders form an eligible application.

The period of desiccation calls for emollients, such as oil, glycerin, and pomades. One of the most frequently exhibited pomades is Wilson's preparation, which has the following composition:

R Benzoës pulv., gr. 75;  
Adip. suilli, ʒiv.;  
Digere, cola et adde  
Zinci oxydati, ʒiii. M.  
F. Unguentum.

In the chronic form of eczema the following indications are to be fulfilled: 1, To detach the scales and crusts which surround the affected parts; 2, to dry up such parts as are still moist; 3, to remove the infiltration, hyperæmia, and desquamation of the skin. The choice of the proper medicines and methods of treatment which will best fulfil these indications in each given case, and the perseverance in this medication, constitutes the secret of the successful treatment of eczema. After this brief review of the general therapeutics of eczema the author passes to the discussion of the special drug proposed by him as a cure of eczema, *viz.*, resorcin. This drug, discovered in 1864 by Barth, belongs to the group of dihydroxybenzols, in which two atoms of the hydride of benzol ( $C_6H_6$ ) are replaced by two hydroxyls (HO). It is obtained by the fusion of the resin of galbanum or the benzoldisulfonic acid with caustic potash.

Resorcin presents small, colorless crystals,

striking a reddish tint on contact with air, is easily dissolved in water, alcohol, ether, and glycerin, less so in oils, fats, and vaseline. The taste of resorcin is sweetish and pungent, and its odor recalls that of phenic acid. The antiseptic properties of the drug, are well established, and, alongside of its antipyretic, caustic, and hæmostatic virtues, as demonstrated by the labors of Andeer, Brieger, and Lichtheim, qualify the drug *a priori* as an eligible application in eczema. Hithertofore resorcin has found a limited but by no means an unsuccessful application in the catarrhal affections of the respiratory passages, in febrile affections, especially in connection with antipyrin, and, through the recommendation of Andeer, also in certain skin-diseases, such as erysipelas, scarlatina, pemphigus, leprosy, and wounds of an infectious nature, and burns.

The author of the paper which we are abstracting, Dr. Wyss, happened to suffer from an eczematous condition on both hands, and used a pomade of vaseline containing ten per cent. of resorcin with the view to lessen the intolerable itching subsequent to the vesicular eruption and the infiltration of the skin. The effect was surprising, itching and infiltration disappearing rapidly after the application of the pomade. These good results obtained with resorcin on his own person were later, likewise, obtained in the treatment of other cases of eczema. Wyss employed resorcin in the following forms :

1. As a powder, associated with poudre de riz, talc de Venice, and other bland bases :

R Pulv. amyl. oryz., ʒv;  
Resorcini, ʒss-i. M.  
F. pulv. subtiliss.

The hygroscopic tendency of resorcin offers, however, some difficulty in properly preserving these preparations.

2. In a solution of oil, which dissolves but little of the drug :

R Resorcini, gr. xv-xxx;  
Ol. oliv.,  
Ol. amygdal., ʒi ʒi.

3. In a solution of glycerin :

R Resorcini, ʒi;  
Glycerini, ʒv.

4. In the form of a pomade :

Vasellini flav. sive axung., ʒv;  
Resorcini, gr. xlv-lxxv.

Wyss tried the drug in three forms in nu-

merous eczematous affections of the nose, face, ears, and extremities. The following were the principal effects observed from this medication: The preparations of resorcin, applied on an eczematous eruption during its period of humidity, form, by the coagulation of the albumen of the secretion, a protective disinfectant cushion, which, without being irritant, stimulates the formation of the epidermis, and alleviates the pain and itching.

In the desquamative period, the pomade or glycerite of resorcin causes the fissures of the skin which may still exist to rapidly cicatrize. The new epidermis, stimulated by the action of resorcin, readily expands, and acquires the normal power of resistance.

Wyss details six cases of eczema successfully treated by preparations of resorcin. In all he has treated about thirty cases, and expresses himself well contented with the results obtained by resorcin. He adds that in no instance has he observed symptoms of irritation after the use of the remedy, such as have been observed after the internal administration of doses exceeding 45 grains. The most favorable periods to exhibit resorcin appear, in the judgment of Wyss, to be the times when the eruption shows a discharge, and when the drying-up process begins. In the former stage the inflammatory congestion has disappeared, and in the latter we can usually still find discharging surfaces and fissures between the scales and crusts. Wyss urges other dermatologists to try the remedy, and to confirm its curative value observed by himself.

#### THE TREATMENT OF OLD CORNEAL OPACITIES.

In the last number of Graefe's *Archiv für Ophthalmologie*, DR. DANTZIGER advocates the treatment of old opacities of the cornea by friction performed daily, and continued for two or three months if necessary. When the opacity is of moderate size, but of considerable density, it is recommended that it should first be scraped away, and the friction, or "massage," commenced as soon as the epithelium has been reformed. The scraping is performed with a Graefe's knife, used in the manner in which one scrapes away a blot with a penknife. Antiseptic precautions are used, and iodoform is applied as a dressing; cocaine produces sufficient anæsthesia. Atropine and warm fomentations are used if the reaction be very great; by the fifth to the eighth day the epithelium has generally been reproduced

and the "massage" is then commenced. A minute piece of Pagenstecher's ointment is introduced, and the upper lid is then moved from side to side over the cornea with the forefinger, with a rapid to-and-fro movement, for about half a minute. Some hyperæmia is produced, which should not last more than a few minutes; if it last as long as half an hour, the treatment must be used cautiously, and may have to be abandoned. The author gives a detailed account of ten cases, in four of which the friction was preceded by scraping. With the exception of three, all were opacities which had existed in a stationary condition for more than three years, and in all except one (in which the whole cornea presented a grayish opacity) there was a very great improvement in vision, sometimes without any obvious clearing of the cornea. An improvement from  $\frac{20}{200}$  to  $\frac{20}{20}$  in three months would, perhaps, about represent the average result of the cases, but in some it was much better. Those who know how very intractable these cases are under ordinary treatment, will welcome any method which offers a reasonable prospect of ameliorating their condition; and should these results be borne out by wider experience, a very valuable addition will have been made to the resources of ophthalmic surgery.—*Brit. Med. Journ.*, February 20, 1886.

#### THE MANAGEMENT OF PLACENTA PRÆVIA.

DR. MALCOLM MACLANE offers the following rules as those which should best govern the treatment of placenta prævia (*Amer. Journ. Obstetrics*, March, 1886):

*First.*—In any case avoid the application of all chemical styptics, which only clog the vagina with inert coagula, and do not prevent hemorrhage. At the very first, the patient should be put in a state of absolute rest,—body and mind,—and a mild opiate is often desirable at this stage to quiet irritation.

*Second.*—Inasmuch as the dangers from hemorrhage are greater than all else to both mother and child, at the earliest moment preparations should be made to induce premature labor; and labor being once started, the case should be closely watched to its termination by the accoucheur.

*Third.*—In primiparæ, and mothers with rigid tissues, the vagina should be well distended, by either the colpeurynter or tampon, as an adjuvant to the cervical dilatation.

*Fourth.*—In the majority of cases generally, and in all cases especially where there is

reason to believe that rapid delivery may be required, it is more safe to rely upon the thorough continuous hydrostatic pressure of a Barnes's dilator than on pressure by the foetal parts.

*Fifth.*—Where the implantation is only lateral or partial, and where there is no object in hurrying the labor, bipolar version, drawing down a foot, and leaving one thigh to occlude and dilate the os, may be practised according to the method of Braxton Hicks, except in cases where the head presents well at the os, when,

*Sixth.*—The membranes should be ruptured, the waters evacuated, and the head encouraged to engage in the cervico-vaginal canal.

*Seventh.*—In the majority of cases, podalic version is to be preferred to application of the forceps within the os.

*Eighth.*—In some cases, in the absence of sufficient assistance or the necessary instruments, the complete vaginal tampon, in part or wholly of cotton, may be applied and left *in situ* until (within a reasonable time) it is dislodged by uterine contractions and the voluntary efforts of the mother. In case of favorable presentation,—occiput or breech,—the tampon will not materially obstruct the descent of the child, and in some cases the tampon, placenta, and child will be expelled rapidly and safely without artificial assistance.

*Ninth.*—The dangers of septic infection by means of the tampon or india-rubber dilators are so slight, if properly used, as not to be considered as seriously impairing their great value.

*Tenth.*—Whenever it is possible, dilatation and delivery ought to be deliberately accomplished, in order to avoid maternal lacerations.

*Finally.*—As cases of placenta prævia offer special dangers from post-partum hemorrhages, septicæmia, etc., the greatest care must be exercised in every detail of operation and nursing, to avoid conveying septic material to the system of the mother.

Absolute cleanliness, rather than chemical substitutes for that virtue, should be our constant companion in the practice of the obstetric art.

#### TEREBENE AND TERPINE.

DR. WILLIAM MURRELL writes to the *British Medical Journal*, February 27, 1886, that he has received so many letters from physicians in different parts of the country giving the

results of their experience with terebene in the treatment of winter-cough, that practically there has been an informal collective investigation. He states that out of ninety-four additional cases reported to him, distinct success is recorded in eighty-one. In six of the cases of failure, a further investigation showed that there had been an incomplete diagnosis, the patient suffering from some complication, such as aneurism or aortic disease, the existence of which had not been previously suspected. In ten cases the patient complained of nausea after taking the medicine, and in several instances when inhaled from lint, it excited coughing and apparently acted as an irritant. Dr. Murrell's explanation of the latter fact is that much of the terebene in the market is very impure. According to Dr. Murrell, terebene improves as it grows older, becoming bland and oily. Reports sent to Dr. Murrell also speak highly of the benefit of terebene in acidity and flatulency, and other forms of dyspepsia.

According to the Paris correspondent of the *British Medical Journal* of the same date, Dr. DESCROIZELLES adds his testimony to that of Dr. Murrell as to the value of terpine in chronic bronchitis simulating tuberculosis. The patient was a boy  $8\frac{1}{2}$  years old, small and delicate; he had been previously treated at the same hospital for pleurisy on the right side. He coughed, vomited, and spat blood; had night-sweats, completely lost his appetite, and was too weak to move. Very little could be learned concerning his antecedents. In the right infraclavicular region there were dulness on percussion, a cavernous *souffle*, and subcrepitant *râles*. The sputa were abundant, both mucous and purulent, and mixed with blood. The axillary temperature rose to  $38.6^{\circ}$  Cent. ( $101.5^{\circ}$  Fahr.). The pulse was 120, and respirations 40. The chest over the part affected was painted with tincture of iodine, and a gramme (15 grs.) of phosphate of sodium was given daily. The child grew worse, hæmoptysis occurred several times, and there was alternate diarrhœa and constipation. The dulness on percussion became more and more marked at the apex of both lungs, but especially on the right side, where moist *râles*, almost gurgling sounds, were heard, also a cavernous sound. On the left side moist crackling sounds had replaced dry crackling sounds. The child grew weaker and refused food; his cheeks were sunken and flushed, and death seemed imminent. Glycerin and creasote were substituted for phosphate of sodium without any good result. Dr. Descroi-

zelles then decided to administer terpine. Two grammes (30 grs.) of this substance were dissolved in forty grammes ( $1\frac{3}{4}$  oz.) of alcohol and twenty of distilled water, and the child took three or four teaspoonfuls of this mixture daily. A marked improvement followed; less sputa were expelled, and they were free from blood; the appetite increased, the general condition improved, and the patient became convalescent. Lime-phosphate and gentian wine were given instead of terpine. In the interval between the beginning of September and the middle of November the pulmonary symptoms disappeared, and the auscultatory sounds were normal. The child was sent into the country, apparently re-established in health.

#### THE PROPHYLAXIS OF ASTHMA.

DR. DAVID W. YANDELL (*American Practitioner and News*, March 6, 1886) states that he has obtained almost uniform success in his attempts to prevent attacks of asthma in children by the administration of bromide of potassium and atropine. The method is to give 10 grains of potassium bromide in a glass of seltzer water every morning on rising and at bedtime, while the  $\frac{1}{16}$  of a grain of sulphate of atropine is added to the latter dose. This treatment should be continued steadily for several months, while the patient should live in the open air and take a cold sponge-bath daily, and may possibly require iron and strychnine. This method Dr. Yandell states invariably succeeds in children, while in adults asthma has usually existed so long that it has wrought changes in the pulmonary apparatus quite beyond the control of the remedies under consideration. Even in children the full effects of the drugs are only obtained when they are given with the utmost regularity during long periods of time, and in doses sufficient to produce their distinctive physiological effects. Dr. Yandell states that he has treated nine cases by this method occurring in patients aged respectively, one of 6 years, three of 10 years, two of 11, one of 12, one of 13, and one of 14. All recovered but two, and in neither of these was the treatment fairly carried out by the parents. None were dismissed under fifteen months, while two were under treatment for two years. In five of the nine cases the disease was hereditary. Eight of the nine were unmistakably neurotic, and this fact may serve as the reason for the success of the treatment.

*THE COMBINED USE OF COCAINE AND  
NITRATE OF SILVER IN CERTAIN  
SUPERFICIAL AFFECTIONS OF  
THE EYE.*

At the meeting of the Medical Society of London held February 22, 1886, MR. BRUDENELL CARTER (*British Medical Journal*, February 27, 1886) read a short paper on this subject, to the effect that while local applications of nitrate of silver were often of great service in congestive ulcerative affections of the eye, it was generally quite undesirable and unnecessary to allow its action to spread beyond the particular areas; one of its effects being, he said, to remove the corneal epithelium when allowed to come into contact with it. It was generally somewhat difficult to limit this action, owing to the pain caused by its use and the accelerated secretion of tears which ensued; and it was to mitigate these conditions that cocaine was so useful. By destroying sensation temporarily it allowed the operator to apply his remedy with all the delicacy and certainty he could desire, and the lachrymal secretion did not increase so as to interfere with what he was doing.

*THERAPEUTICS OF BURNS.*

DR. ALTSCHUL, a surgeon of a large steel-factory, having had an excellent opportunity of testing the various therapeutic measures, communicates his experience to the *Monatsh. f. prakt. Dermat.*, No. 1, 1886. All known, or rather recommended, remedies were tried, with the view of securing an ideal healing without suppuration. The aseptic measures were of course found the most and only eligible ones. Iodoform appears to have furnished the most satisfactory results. Only in burns of the first degree dressings with argillaceous earth proved superior to lessen the severity of pain. Iodoform can be said to prevent with certainty suppuration in burns of the second and third degrees. At first Altschul tried the powder-dressings; later a ten per cent. iodoform-gelatin, after the recommendation of Pick. As the latter, however, was found hard to preserve, he followed Unna's advice, and employed an iodoform paste, and in time arrived at the conclusion that the iodoform bolus-paste was the choicest application of all. The formula for this paste is as follows:

- R Boli alb., ʒss;  
Olei olivarium, ʒi;  
Liq. plumbi subacetici, ʒvi;  
Iodoformii, 10-20 per cent. = ʒii-iv.

In order to prepare this paste, the bolus is to be first mixed with oil, as otherwise the subacetate of lead would form an insoluble mass with the bolus. Finely-powdered roasted coffee disguises the odor of iodoform very effectually.

*THE TREATMENT OF VARICOCELE BY  
EXCISION.*

The various methods adopted for the cure of varicocele go far to prove that as yet no one plan is so satisfactory as to leave nothing more to be desired. Of the various means which have been proposed, MR. A. W. MAYO ROBSON (*Brit. Med. Journ.*, February 27, 1886) thinks that none equal in completeness and safety the complete excision of the bundle of enlarged veins.

After any radical operation for varicocele, there must of necessity be a greatly disturbed circulation in the scrotum, and a liability to hydrocele or slight orchitis, and this he has found occasionally even in subcutaneous ligation of the veins; but orchitis supervened only once, and then in a syphilitic subject, who had had specific orchitis a short time before being treated for varicocele.

The train of nervous symptoms frequently accompanying varicocele is often so severe as to demand treatment; and, when some tangible cause is found, such as a varicose condition of the pampiniform plexus, producing congestion and neuralgia, and ultimately atrophy of the testis, it is the surgeon's duty to give relief, especially when it can be done without danger. The operation of excision is performed as follows:

The skin of the scrotum, having been shaved and well washed, is enveloped in a carbolic dressing, which is left on for twelve or twenty-four hours preceding operation.

After the patient has been anesthetized, and every antiseptic precaution adopted, the cord of the affected side is caught between the left finger and thumb over the site of the varicocele; the vas deferens, which is easily felt, is allowed to slip backwards, leaving the enlarged veins within the grasp.

A vertical incision of three-quarters of an inch is now made through skin and fascia, quite down to the veins which immediately bulge through the wound, and are caught between the finger and thumb of the right hand; the finger-nail then serves to break through a film of fascia which separates the veins from the vas deferens. A double No. 2 catgut ligature is passed round the bundle of

veins, and the two ligatures thus placed *in situ* are tied about an inch or more apart, the intermediate varicocele being completely cut away.

No bleeding occurs, as a rule, and the wound is so small, and falls so well together, that sutures are scarcely required. A small catgut drain may be left in, but this is not absolutely necessary. The wound is covered with carbolized gauze, and over this is placed a good pad of salicylic silk or wool. In some cases the dressings are not removed for a week, when the wound is completely healed; but, when a drainage-tube has been left in, it should be removed on the second day.

Mr. Robson reports a number of cases successfully treated by the above plan.

## Reviews.

---

THE USE OF THE MICROSCOPE IN CLINICAL AND PATHOLOGICAL EXAMINATIONS. By Dr. Carl Friedlaender. Translated by Henry C. Coe, M.D. Pp. 195, 12mo.

New York: D. Appleton & Co., 1885.

The appearance of an English translation of Friedlaender's very popular and excellent little volume is a welcome addition to our book-lists.

For such of our readers who may not be familiar with the scope of the book, it may be of interest to indicate its contents. The text has been written entirely from the standpoint, and for the guidance, of the clinical worker, consequently it discusses only those subjects likely to be brought to the notice of the practitioner, making no pretension to systematic completeness.

Of the seven chapters, four are devoted to brief descriptions of the microscope, objectives and accessories most desirable for the special needs of medical work, reagents, methods of preparation, including an excellent review of the most valuable stainings.

The sections on the identification and staining of the schizomycetes will be found very valuable. To those not yet familiar with Gram's method of staining bacteria we strongly recommend a trial of this admirable method.

The remaining chapters give directions for examining living tissues, fluids, and secretions, including blood, sputa, pus, urine, etc., and, finally, solid elements and tumors.

In judging of the merits of the book, it must be distinctly borne in mind that its object is solely to facilitate clinical and patho-

logical investigations. The simplest means by which these ends can be obtained are usually the ones suggested. It follows, therefore, that many procedures described are crude in comparison with the nicety of the present approved methods of microscopical technique. Most will admit, however, the wisdom of Friedlaender in recommending only those simple manipulations which are possible for the busy man, to whom elaborate methods are but sad spendthrifts of precious time.

While Dr. Coe has earned our thanks by his translation, a somewhat more liberal rendering frequently would have improved the smoothness of the text. The retention of such words as "instrumentarium" certainly adds little to the enjoyment of the reader.

The title-page is faced by a reproduction (by no means an improvement on the original) of the excellent drawings by Friedlaender of a number of the more important pathogenic bacteria. The little book in its English dress will undoubtedly gain many new friends.

PRACTICAL HISTOLOGY AND PATHOLOGY. By Henge Gibbs, M.D. Third edition, pp. 195, 12mo. Philadelphia: P. Blakiston, Son & Co., 1885.

The necessity of three editions within less than twice that number of years certainly argues well for the value and popularity of any book. Examination of the present edition of this little volume still further confirms the favorable opinion of its merits. The additions embrace new staining formulæ and other matters of interest. The restoration of carmine to its place among the stains was sanctioned by universal opinion.

The chapter on section cutting seems to have been neglected in the revision. Notwithstanding the very general use of the recent forms of sliding microtomes, all mention of these admirable instruments—by whose introduction the possibilities of microscopical technique have been greatly extended—is omitted; likewise descriptions of the methods of paraffine and celloidine embedding are wanting.

While fully appreciating the convenience of the freezing methods, evidently great favorites with our author, the ignoring of these very important recent methods, which are so well adapted to insure exact results, is to be regretted. In so excellent a guide a few hints regarding refined methods might with great propriety have been included. The book will continue to be a favorite with those entering upon practical histology, and is to be appreciated as a source of trustworthy advice.

SELECT EXTRA TROPICAL PLANTS READILY ELIGIBLE  
FOR INDUSTRIAL CULTURE OR NATURALIZATION.

By Baron Ferd. von Mueller.

Detroit, Mich. Geo S. Davis.

In this, the latest work of Baron Mueller, we have a compact octavo volume of 450 pages, replete with useful information. In its original form the matter of this volume was presented as a series of contributions to the Victorian Acclimatization Society of Australia; but, being accessible to only a limited number in this connection, it was collected into a volume published for the government in Melbourne, 1876. That it supplied a long standing want is proved by the fact that it was soon reissued in India, under the auspices of the central government; in New South Wales, for the benefit of colonists; and went through a German translation in Cassel. Its issue, through the enterprise of a Detroit publisher, now makes it more generally accessible to American readers.

Colonists in a new locality, or persons of culture, desirous of improving their surroundings by a judicious cultivation of useful or ornamental plants, are often quite at loss for proper guides to the collection of suitable subjects for trial. While many experiments have been conducted, and much valuable information accumulated, this material is generally inaccessible to the persons most interested. Scattered through the proceedings of learned societies or stray local journals, it is practically lost. What was needed was a judicious compilation of this vast array of facts. This burdensome task Dr. Mueller has undertaken, and, as the volume before us testifies, has accomplished with signal success.

The species are arranged in alphabetical order, without regard to family relation, and are hence conveniently referred to. The notes under each species are concise, generally well selected, and in non-technical language, which will better meet the wants of the special class of persons for whom the book was prepared. Convenient lists are arranged at the end of the volume, bringing species together under such comprehensive heads as alimentary plants, embracing those yielding (1) herbage, (2) roots, (3) grain, (4) fruits, etc.; condiment plants, hedge plants, dye plants, fibre plants, scenic plants, etc. The geographical index, which embraces the plants of each country, is also an interesting feature.

In several minor points of classification we differ from the arrangement followed. For instance, nearly all the Coniferæ, including *Abies*, *Larix*, and *Picea*, are classed as species

of *Pinus*. In a work like this the points of difference should have been insisted upon, since they are so apparent even to the unscientific. In only one instance have we noted a positive error,—i.e., the North American tulé is *Scirpus validus*, and not the root of a *Sagittaria*.

On the whole, however, it is a very satisfactory book, and we hope it will soon be in the hands of all lovers of plants.

PRACTICAL HUMAN ANATOMY: A WORKING GUIDE FOR STUDENTS OF MEDICINE, AND A READY REFERENCE FOR SURGEONS AND PHYSICIANS. By Faneuil D. Weisse, M.D., Prosecutor (1863-65) to the late Valentine Mott, M.D., LL.D., Emeritus Professor of Surgery and Surgical Anatomy, Medical Department of the University of the City of New York; Professor of Practical and Surgical Anatomy, Medical Department of the University of the City of New York; Professor of Anatomy, New York College of Dentistry. Royal octavo, 468 pages of text. Illustrated by 222 lettered plates.

New York: William Wood & Co., 1886.

This book is evidently the work of a thorough and skilful anatomist, and one who has devoted many years to the teaching of practical anatomy, knowing exactly when and how to show his work so as to be viewed in the best light. The author has apparently intended the book more for the use of the student in the dissecting-room than for the general practitioner, although the latter will find the plates a most valuable and ready field of reference.

It is arranged in a series of twenty-seven dissections, including all parts of the body excepting the eyeball and auditory apparatus, and we agree that these hardly come under the scope of such a work.

At the beginning of each dissection the primary incisions for the removal of the skin are shown in wood-cuts, which are much better, being fewer in number and simpler, than is figured in Gray and many of our dissectors. All through the text and at each stage of the dissection much valuable information is given in small type, stating what is to be removed and what preserved as the dissection progresses. We are glad to see the use of the scissors advised, which are seldom used in this country except by prosectors and advanced students.

No reference is made to surgical or applied anatomy, and nothing is spoken of which cannot be demonstrated with the unaided eye; therefore the structure of any part that requires the aid of the microscope will have to be sought for in histologies.

The plates, two hundred and twenty-two

in number, are nearly all from nature. They are indeed works of art in their way as faithful studies of actual conditions, and represent an amount of work on the part of the author and artist that cannot fail to be appreciated by the student and practitioner.

The plates of the male and female perineum, thigh, region of the neck, and thorax are especially worthy of mention.

The text is short, and in many instances unsatisfactory, and with great tendency to repetition. For instance, we find the description of the anterior tibial nerve occurring in four separate paragraphs in seven consecutive pages. The mammary gland is disposed of entirely in six lines.

The anatomy of the inguinal region, particularly the part which concerns hernia, is not made as clear in the text or drawings as might be desired, and we fail to find any mention of the inguinal canal whatever. This might be treated without the fear of encroaching upon the field of surgical anatomy in any way. Some errors and omissions have crept in, *e.g.* :

In the ligaments of the knee-joint no mention is made of the ligamentum mucosum or ligamenta alaria. Although composed of synovial membrane, the former is the first thing noticed when the knee-joint is opened anteriorly, and plays a most important part in retaining the patella in position after amputation through this articulation.

The subcrureus muscle is described as being attached to the anterior ligament of the knee-joint, whereas it is inserted into the upper portion of the synovial sac of this articulation, its function being to raise the membrane when the leg is extended, so as to be uninjured by the play of the patella.

In the articulations of the fingers and toes a posterior ligament is described, rather contrary to present teaching, as the extensor tendon covers the dorsal portion of the joint, and plays the part of a ligament.

The three phalangeal rows are mentioned as composed of five phalanges, four phalangines, and five phalangettes. If this were generally adopted it would save much unnecessary confusion in speaking of the finger.

We find the scalp mentioned as being composed of but three layers, whereas five are easily demonstrable.

The anconal space, spoken of as just anterior to the elbow-joint, is divided into two fossæ by the biceps tendon, and is analogous to the popliteal space in the lower ex-

tremity. We are at a loss to see why it should be so called, as anconal pertains to the region on the opposite side of the arm.

We venture to find fault with some parts of Professor Weisse's book, not from any spirit of hostility, but rather to suggest for future editions. We congratulate the author on his book, and also on procuring the services of so talented an artist as Mr. Maximilian Cohn.

Typographically the volume is most praiseworthy, and the publishers, William Wood & Co., have done their part in making the book most acceptable to the profession.

#### THE METHODS OF BACTERIOLOGICAL INVESTIGATION.

By Dr. Ferdinand Hueppe. Translated from the German by Hermann Biggs, M.D. 12mo, pp. 214.

New York: Appleton & Co., 1886.

The original of this translation appeared in February, 1885, and the leading points of value in it have already been incorporated and presented to American students in Dr. Dolley's "Technology of Bacteria Investigation" (Boston, S. E. Cassino & Co., 1885). The present translation is, however, none the less welcome. It enters well into details in describing methods, is illustrated with some thirty wood-cuts of apparatus, and devotes a few pages to the morphology of bacteria. The colored plates of the original have been omitted in the translation.

The author—docent in hygiene and bacteriology in the chemical laboratory of R. Fresenius in Wiesbaden—has been a student of Prof. Robert Koch, and prepared the book at the request of that investigator, the only other books on methods in German at that time being Plaut's "Färbungs Methoden zum Nachweis der faulniss und pathogenen Mikroorganismen" and Kaatzer's "Technik des Sputum Untersuchungs auf Tuberkel-Bacillen." These were both superficial pamphlets, and the best articles on the subject were unavailable from being scattered through various journals and reports, and hidden in accounts of experiments.

The subject is treated in seven chapters; spontaneous generation and morphology are handled briefly in the first and second, followed by directions for staining and mounting.

Chapters three, four, and five are devoted to culture methods, inoculation, and general biological problems respectively, while the sixth chapter treats of the special methods employed in the investigation of earth, water, and air from a hygienic stand-point. In the last chapter bacteriology as an object of instruction is considered.

The importance of instruction for medical students in the methods of investigating bacteria and in the relations held by them to special diseases, hygiene in general, and many physiological problems, is being daily more thoroughly appreciated. Copenhagen, Munich, Göttingen, Breslau, and Wiesbaden now furnish special courses of instruction in connection with their respective universities. In this country special instruction can be had in the Carnegie Laboratory of New York, in the Biological Department of the University of Pennsylvania, and elsewhere; but as yet there have been no special laboratories established for bacteriological research.

Dr. Hueppe is right in saying (p. 213), "The actual every-day necessities lie at present more in the preparatory courses. Every practising physician, and especially every medical officer, is desirous of so far informing himself concerning these methods as to be able to follow intelligently the recent investigations, since the morphological and biological foundations of the general processes of decomposition and the ætiology of infectious diseases have assumed tangible form through the development of the methods."

Bacteriological instruction should, however, be placed in the hands of men thoroughly versed in the technique of the immediate subject, and at the same time possessed of a training in general biology sufficiently broad to enable them to maintain a conservative position amidst the wrangling of rival investigators.

The bitterness that exists between Koch and Pasteur should not be shared by American physicians, and the unseemly haste with which the medical profession have chosen sides in questions concerning the ætiological agency of bacteria should in the future be avoided.

Anything tending to enable the would-be investigator to select the good out of the conflicting experiments constantly reported is of value. For this reason Dr. Biggs's translation of Hueppe's work is to be welcomed. The work of translating has been well done; the index is complete; and, while the book does not replace or displace any of the works already in the market, it will be found a valuable addition. There is now no excuse for idleness among American investigators; with such books at hand as are to be had in English by Klein, Stemberg, Dolley, Woodhead, and Biggs every essential step in manipulation may be acquired, and complete references found to all papers up to the last few

months in connection with any special branch of the subject.

ORGANIC MATERIA MEDICA AND THERAPEUTICS. By James Young Simpson, M.D.  
New York: J. H. Vail & Co., 1885.

The writer has compiled this book with a view to affording the medical profession the use of a synoptical *materia medica*. Dealing with organic remedies, under each head we find the English name, origin, natural order, habit, constituents, description, solubility; then its general, physiological, therapeutical, and toxicological action, and its various pharmaceutical preparations. Everything is concisely stated, and if at times somewhat dogmatic, the author pleads the necessity for brevity and his own careful study of authorities. As a means of impressing the outlines of *materia medica* and therapeutics on the mind the book will prove useful. The practitioner who would refresh his memory, as well as the student, may read this book with profit.

ESSENTIALS OF VACCINATION: A COMPILATION OF FACTS RELATING TO VACCINE INOCULATION AND ITS INFLUENCE IN THE PREVENTION OF SMALL-POX. By W. A. Hardaway, M.D., etc.  
St. Louis: J. H. Chambers & Co., 1886.

The author has collected together about all the useful information concerning vaccination that is extant. His manner of treating the whole subject is unpretentious and modest. For most of his facts he gives his authority, and a perusal of his book—the operation being simple—will make any person of average understanding a better and more intelligent vaccinator than most men who vaccinate. Of the American vaccinator he has by no means a high opinion. He quotes Reynolds's system for his authority in saying "that vaccination has been worse performed generally in England, its birthplace, than in any country in Europe;" but adds, "I doubt if there is a civilized land where less is known of the theory and practice of vaccination than in America." This is owing to "vaccination from arm to arm being comparatively unknown." Of course, vaccination from the "scab" meets with no support from him; yet we imagine it possible that the value of such vaccination has been much underrated, and would hazard the opinion that had such vaccination been thoroughly performed,—*i.e.*, with several insertions and from carefully selected human crusts, even though of long descent,—the individual so vaccinated would have fared as well in the presence of contagion as the average population vaccinated with calf lymph.

The great uncertainty of the latter leads to so many being left in the unsuccessful list, while its violence at times has been simply terrifying, not only to parents and friends but even to the vaccinator himself. Certainly, in regard to the transmission of vaccinal syphilis there seems to be less danger, in using human crusts, well selected, than in arm-to-arm vaccination.

Of the danger of transferring bovine diseases in general the author makes light, though why and on what just grounds he fails to say. Of one thing, however, the reader will be thoroughly convinced—if convinced he ever can be—after reading Dr. Hardaway's little book, and that is of the inestimable value, despite all drawbacks, of vaccination.

CLINICAL NOTES ON UTERINE SURGERY, WITH SPECIAL REFERENCE TO THE MANAGEMENT OF THE STERILE CONDITION. By J. Marion Sims, A.B., M.D., etc. Memorial Edition.

New York: William Wood & Co., 1886.

The speculum of Sims was the gate of gynecology through which, and through which alone, the eager hordes pressed on to the fertile fields beyond; and they are still pressing on. The extremely modest title of Dr. Sims's book scarcely prepared the medical world for its contents. Extreme modesty of a certain sort marks its pages, though dealing with topics of the most delicate nature, and at a time, too, when the world was not yet educated to its present insensitive conditions as to such matters, at a time when the student was highly favored who was admitted to view operations of the character herein described. In fact, Dr. Sims's style in the treatment of these topics is to be eminently commended, much more, perhaps, than his experiments in regard to the sterile condition which he so carefully narrates; and it is probably fortunate that these experiments and their result in practical failure were so honestly set forth by so eminent a man at so early a stage in the growth of gynecology. Had this branch of the art been pursued as eagerly as some others, it would soon have required a child far wiser than the proverbial one to "know his own father." But in reading again this reprinted work one is struck at every page with the immense value of Dr. Sims's labors. So many of its suggestions and procedures have become household words and household facts in the medical world that we have ceased to remember our indebtedness. The publishers have done us all a service in the reissue of the book, and those who do not possess it

should hasten to own one of the few true classics of modern medicine.

DRAINAGE FOR HEALTH; OR, EASY LESSONS IN SANITARY SCIENCE. By Jos. Wilson, M.D. Second edition, with Important Additions.

Philadelphia: P. Blakiston, Son & Co., 1886.

The lessons are easy, but the scholars are often dull of understanding. The book is devoted mainly to drainage. It deals with general principles, well illustrated by cases in point. The grand principles of drainage—of fields and swamps, as well as the streets and houses of the city—are forcibly put before us. The rural resident will find as much instruction in the book as the citizen who dreads typhoid and diphtheria. The subject of traps is discussed, and, leaving the subject somewhat, we have a chapter on parasites, and some declamation concerning boards of health. The wood-cut illustrations are intelligible, and the author's style interesting, and one gets a good deal of information on the kindergarten principle before he knows it. It is a good book for the general reader, since it is sound and not too technical.

ELEMENTS OF PHARMACY, MATERIA MEDICA, AND THERAPEUTICS. By W. Whittle, M.D. Third Edition. London: H. Renshaw, 1886.

This is a small volume of nearly six hundred closely-printed pages; the first half of which is occupied with the discussion of pharmacy, administration of medicine, and materia medica; the last half being devoted to therapeutics and certain other matters. The materia medica refers to the British Pharmacopœia; and the description of the various remedies, although exceedingly brief, is sufficient we suppose for the purposes of the medical student. The discussion of therapeutics is on the whole good, although we notice certain things which seem to us might be better. Thus, in iodoform the exact amount which it is dangerous to use on an external wound should be stated in grains, and we doubt very much the truth of the assertion that pilocarpine is eliminated by the kidneys and not by the skin.

The close relation of this book to the British Pharmacopœia will prevent its being used in this country by medical students, but a careful looking over of a good many of the articles convinces us that the work well deserves the success which it has received in England. The writer is apparently well posted in English literature, at least, and is evidently a close reader of the THERAPEUTIC

GAZETTE. New remedies, such as arbutin, boldo, tannate of cannabin, hyoscine, delphine, receive brief but careful consideration. At the close of the volume is a most elaborate table of the chemical reactions of the official remedies, which we have no doubt is very valuable to students who have to pass examinations in chemistry, and affords most excellent material for rapid forgetting. In contrast with this table, as affording excellent material for permanent remembrance, are the few pages devoted to prescription-writing. They seem to us the best consideration of the subject that we can remember to have read. The so-called index of poisons and their antidotes is, to our thinking, very brief, and especially and emphatically do we dissent from the statement that "Murrell's 'What to do in Poisoning' should be in every practitioner's instrument-bag." The contents of that book ought to be in every practitioner's head. The subject of poisons is so important, and covers so little ground, and the knowledge when wanted is wanted so badly, that there is no excuse for the practitioner's not being thoroughly posted in it.

#### REVUE SCIENTIFIQUE.

Recent numbers of the *Revue Scientifique* have contained the following articles of general medical interest.

February 6, 1886 :

Military Medicine in 1866 ; The Fermentation of Milk (M. Bourquelot) ; Biographies of Carpenter, Huxley, and Hooker.

February 13, 1886.

Instinct and Intelligence (M. Hermann Fol) ; The Derivatives of Menthol (M. Arth).

February 27, 1886.

Instinct and Intelligence (M. Hermann Fol) ; Sterility and Fecundity of Parisian Families.

#### THE ABDOMINAL BANDAGE AFTER LABOR.

To the Editors of the THERAPEUTIC GAZETTE :

GENTLEMEN :—On page 333 of the *Medical Record*, under the caption of "The Abdominal Bandage after Labor," attention is directed to Prof. Czerny's ideas of abdominal bandaging, as set forth by him in the *Centralblatt für Chirurgie*, January 16, 1886. I would like to ask the question that often presents

itself, What is the general custom of American practitioners in reference to the use of the bandage in question? The popular opinion is that the bandage is designed exclusively to aid in restoring the form possessed previous to pregnancy. I had always supposed the professional idea in the use of the bandage was to give support to the uterus and its appendages during the period of involution. I believe the theory wrong and the practice worse than useless. In point of fact, the results sought after by those who advocate the use of the bandage are either negative or directly opposite those desired. Especially is this true, to say the very least, of the bandage as commonly applied.

Instead of a support, it actually retards the restoration of the uterus to the normal condition. After an experience of several years, with a fair average of cases, country practice, I have come to regard the bandage of so little importance that I leave its use almost entirely to the wish of the patient. To some it carries with it a sense of comfort in supporting the abdominal parietes that may recommend its use in exceptional cases. Many of the diseases from which the mothers of human-kind are suffering refer their origin to the lying-in chamber. Not because, as some would infer, of the absence of, or the improper use of, the abdominal bandage, but because of the inconsistencies indulged in by many subsequent to the parturient act. Women will insist on leaving their beds and performing many items of work not permissible in view of their physical condition, and this, too, in opposition to the dictates of common sense and the earnest protests of their medical attendant. And the results are confronted almost daily by the busy practitioner in the form of displacements, cervicitis, metritis, ovaritis, and many other diseases of the uterus and its appendages, with their concomitant symptoms and consequent sufferings and misery. The question is not easily answered, How can the accoucheur impress upon those subject to his professional care the importance of giving rest to those delicate and highly sensitive organs that have but recently and are still undergoing important changes? The beauty and symmetry we so much admire, the strength of body and vigor of mind so essential to woman in the discharge of her maternal duties, depend more upon the proper observance of natural law than upon any mechanical contrivance or device of man.

E. E. BRITTON, M.D.

SPENCER, OHIO, March 23, 1886.

(From our Special Correspondent.)

## ANTIPIRETICS IN VIENNA.

We find hyperpyrexia treated in Vienna not only by drugs, but by the application of cold in compresses, packs, baths, and in a most efficient and convenient manner by Leiter's coils, or "kühlapparat." This consists of flexible metal tubing, wound in coils of varying shapes and sizes, so made as to fit different regions of the body. These coils are connected by rubber tubing with receptacles placed above the patient; cold water traverses the coil, and is discharged by siphon action. A cold compress may be laid over the skin, and the coil lightly bandaged upon this. These coils are lighter, more comfortable for the patient, and more convenient and cleanly than ice-bags. These coils may be connected with an alcohol lamp and hot-water reservoir, and warm applications made if desired. This apparatus has been used in several American hospitals. It has been made lighter and more convenient, until for both doctor and patient it is efficient and agreeable.

Cold compresses are especially used in high temperature with local inflammations, as in puerperal sepsis. Cold packs, followed by the wrapping of a blanket or dry sheet about the patient, are used frequently with children. Hospital wards have movable bath-tubs which can be brought to the bedside, and in which a fever patient can be immersed. Antipyretic drugs in common use are quinine, antipyrin, thallin, and hydrochinon. The latter two are used much less frequently than the former. For rheumatic hyperpyrexia salicylate of sodium is given.

In the clinical wards of Prof. Bamberger antipyrin is given in doses varying from 2 to 3, 4, or 5 grammes (15 to 75 grs.) in twenty-four hours in all hyperpyrexias except typhus abdominalis and rheumatism. In the former quinine is given, in the latter sodium salicylate. Depression is rarely observed after the use of antipyrin; a general erythema is the most common inconvenience experienced. For typhus abdominalis the stimulant properties of quinine are desired. In this clinic thallin is rarely used. Cold applications and packs are in constant requisition.

In the clinic of Prof. Nothnagel experiments have been made by Dr. Jaksch with thallin, and his results have been published in a reprint from the *Zeitschrift f. Klinische Medizin*. He states that thallin is worthy of a further trial, and especially in cases where a

rapid reduction of temperature is necessary. In his experiments the hydrochlorate, sulphate, and tartrate were used, the last being least desirable. The effects of thallin resemble those of kairin, but its use is not attended by the unpleasant stomach and general disturbances which often follow the giving of kairin. Cyanosis and collapse did not occur. Free perspiration accompanies a reduction of temperature, and a subsequent rise of temperature is ushered in by a chill. A lessening of pulse and respiratory rate was observed. In doses of  $\frac{1}{8}$ ,  $\frac{1}{4}$ , or  $\frac{1}{2}$  gramme (2 to 7½ grs.) perspiration and fall of temperature occurred one-half to one hour after taking. Minimum temperature was reached in two, three, or four hours. It will be observed that the best results from thallin were obtained with comparatively small doses, and that its use was followed by no ill effects. The formula for thallin is  $C_6H_5NO$ . Its salts have a somewhat bitter, aromatic taste, are very soluble in water; solutions are acid, and give with ferric chloride a green color.

Cases of sepsis treated in the wards of Prof. Nothnagel are given sodium salicylate, alcohol in free doses, and are treated also by cold applications.

In children's diseases Prof. Monti recommends the very cautious use of antipyretics, because of their depressant effects. He prefers quinine and the application of cold.

Prof. Wiederhofer, at the Saint Anne's Children's Hospital, uses in the hospital antipyrin with good results. In ambulatory cases he does not trust the parents or friends of the child to administer antipyrin, but prescribes quinine instead. He uses also very commonly cold compresses and packs.

In Prof. Spaeth's lying-in wards antipyrin is given to reduce temperature in gramme (15 grs.) doses three times in twenty-four hours. Quinine is used when collapse is imminent. The local use of cold is a routine practice for all puerperal fevers. In the clinical wards of Prof. Carl Braun hydrochinon is a favorite antipyretic. It is given in doses of  $\frac{1}{2}$  gramme, repeated in an hour if needed. Salicylate of sodium is also used in doses of 1 gramme, repeated several times until a fall of temperature occurs. Antipyrin is also given, and no ill effects from depression and collapse have occurred in its administration.

Cold baths are not often employed. Ice-bags are placed upon the abdomen in abdominal inflammations.

In hyperpyrexias occurring in Prof. Billroth's wards antipyrin is given in free doses,

and Leiter's coils are used. In Prof. Albert's clinic quinine is usually administered in pyæmia and surgical fever. As one would expect, antiseptic surgery has little fever to treat, and infrequent occasions for the use of antipyretics.

(From our Special Correspondent.)

## HENOCH ON THE TREATMENT OF PERTUSSIS—NOTE ON THE CASE OF DIPHTHERIA TREATED BY GALVANOCAUTERY—ICHTHYOL.

It will be interesting to our readers, we hope, to gain a full insight into the therapeutics of whooping-cough, as advocated by Henoch. The following, originally a clinical lecture on the subject, embodies the principal views of the Berlin authority.

Pertussis is an affection the treatment of which confers but little credit on those who have embraced the healing art. The enormous figure of the remedies alone, recommended since the oldest times, against this affection is proof enough of its incurability. We know no drug capable of aborting the affection or shortening its convulsive stage; while on the other hand, in its third phase, the so-called stadium decrementi, when the natural healing process has set in, every remedy is apparently successful. The numerous drugs which, following the recommendation of other physicians, have been tried, have been nearly all discarded. At present, Henoch relies solely on one remedy, viz., morphine, which is even superior to the vaunted belladonna medication, and is at least able to lessen the gravity and frequency of the paroxysms, especially the nocturnal ones, without, however, influencing the general course of the disease. Henoch usually prescribes the following:

R Morph. acet. s. mur, gr.  $\frac{1}{4}$ — $\frac{1}{2}$ ;

Aq. dest.,  $\mathfrak{f}\mathfrak{ss}$ ;

Syr. alth.,  $\mathfrak{f}\mathfrak{ss}$ . M.

S.—Two to four times daily a teaspoonful.

If excessive somnolence should set in, the drug is at once to be discontinued. In one instance a child, being treated by morphine, slept for eighteen consecutive hours without being interrupted by the paroxysmal coughs, which of course returned after the passing off of the narcosis. In another case, that of a six-months-old child, there was an actual intoxication proceeding with collapse, contraction of the pupils, and sopor, which, however, readily yielded to cold affusions and analeptic measures. It is therefore necessary to in-

struct the nurses and mothers in every instance of the nature of the prescribed medicine. Using the proper precautions, Henoch states that he has never experienced any accident with the morphine mixture, even if half a teaspoonful of it were given daily for several weeks. He consequently feels justified in preferring this drug to all other narcotics, especially to the dangerous atropine. Still, he regards the morphine only indicated in the graver cases, marked by at least twenty paroxysms within twenty-four hours. In milder cases, inhalations of carbolic acid recommend themselves, which on the ground of the alleged—but hitherto not yet demonstrated—parasitic nature of the affection, appear even theoretically indicated, and have recently acquired a certain reputation with many practitioners of renown, such as Thorner and Burchard. In Henoch's experience this medication has not furnished any constant results, its effects being sometimes remarkably favorable, sometimes doubtful, or again wholly negative. Injurious effects at least have never been witnessed from these inhalations. Their application can be executed in various ways. Henoch uses a one-half per cent. solution of carbolic acid by means of an atomizer, or if this procedure meets with difficulties, orders the air of the sick-room to be impregnated with the same evaporating solution, or a sponge saturated with it to be hung up at the child's bed, over its head, and have the sponge placed several times daily before the nose of the child for a period of several minutes. Other inhalations, such as those of chloroform, benzine, salicylate of sodium, oil of turpentine, tannic acid, and quinine, have all received fair trials, but have not given the expected satisfaction. The same holds true of the internal use of bromide of potassium, of hydrate of chloral, and of quinine. Following the instruction of Dr. Sauerhering, of Stettin (*vide* THERAPEUTIC GAZETTE), the systematic exhibition of quinine in gradually increasing and then decreasing doses has also been tried, and again convinced Henoch that the morphine medication and the carbolic acid inhalations were the best treatment of whooping-cough.

Therefore the idea of aborting or lessening the duration of the affection will have to be abandoned, and the parents must be instructed that a mitigation of the attacks is all that can be expected from the treatment. Fresh air is a decided adjuvant to the prescriptions, though damp and rough weather and the existence of a pronounced bronchial

catarrh contraindicate an out-door sojourn. If the child be attacked during the summer months, one will often be asked whether a trip to the sea-shore be advisable or not. Henoch says that he has often complied with the wishes of parents in this respect, but never saw any benefit from such a change of locality, and the only, though lamentable, result of the journey was often the infection of previously healthy children which came in contact with the sick child at the sea-shore or watering-place. Only exceptionally, as in his own child, he observed a characteristic pertussis disappear in fourteen days after the child had been sent to the Reichenhall Springs. Still, he believes with Trousseau in the existence of so-called abortive cases of whooping-cough, and that the affection in the case alluded to belonged to this category. Trousseau, by the way, has reported a case of genuine pertussis which aborted after a three days' duration.

Your correspondent has obtained some additional data in reference to the young girl treated at the Berlin Charité for diphtheria with actual cautery.

The girl, Martha Tegge, 8 years of age, was presented for treatment on February 9 with diphtheritic deposits on both tonsils, though the uvula and post-pharyngeal wall were free. Decoction of quinine and gargles with chlorate of potassium were ordered. The pulse was 132 and the temperature 38.3° C. On the 10th the cauterization was performed,—*i. e.*, two days after admission to the hospital and about five days after beginning of the disease. This shows that the case was by no means a highly suitable one for the cauterization treatment, as the very initiatory phase of the disease, which can alone be regarded as the proper time for cauterization, had already passed. Pulse 100, temperature 116°, after the cauterization. From this date the course of the pulse and temperature was fluctuating, though a gradual and steady improvement was registered with both. On the day following the operation the deposit had materially decreased in extent, and of course assumed the desired traumatic character, instead of its prior septic one. On the 13th the deposit was pushed off. Unfortunately, the infra-maxillary glands became swollen, assumed a phlegmonous nature, and kept up an elevated temperature. The glandular abscess being opened, the temperature at once went down, and a satisfactory state of the subjective health appeared.

On the 1st of March the patient was seen

for the last time, and was just about being discharged as in every way cured.

It is to be added that both the extent of the deposit and the high elevation of temperature justified the attending physicians in regarding the case from the beginning as a hopeless one. Prof. Henoch will, of course, make further trials with the cauterization in diphtheritis.

The testimonies of the high therapeutic value of ichthyol are too numerous and come from too authoritative sources to be overlooked. There are, however, two drawbacks attached to the remedy which will prove a serious obstacle to its gaining a firm hold with the regular practitioner, *viz.*, the secrecy of its preparation in the hands of a few men (the Ichthyol Company, Cordes; Hermann & Co., in Hamburg), and its liberal eulogization for far too many affections in the lay press.

Your correspondent had an opportunity of trying the local application of ichthyol in six cases of painful tumefaction in the knee, elbow, and other joints following upon various traumatic accidents, such as sprains, fractures, and luxations, and must express an unqualified satisfaction at the rapidity and completeness with which both swelling and pain disappeared under its use. These tests of the remedy were made during a trip from Hamburg to New York on the German steamer "Polynesia" on the crew and passengers, and were duly recorded in the medical journal of the vessel.

The principal utilization of the drug is said to consist in its specific anti-rheumatic virtues, though some clinicians are very positive in declaring the salicylic acid and its allied sodium salts as unquestionably superior. True, Dr. Schwenger, Professor of Diseases of the Skin at the University of Berlin, by the dictatorial grace of Bismarck, praises the drug as an anti-rheumatic of the highest rank, and Bismarck, having been relieved from untold suffering by the aid of ichthyol, did not hesitate to allow his illustrious name to figure as a recommendation of the medicine.

Prof. Schwenger also claims that ichthyol is an unexcelled remedy in neuralgia, sciatica, muscular rheumatism, and in all skin-affections. Your correspondent knows of a case of ichthyosis and of psoriasis which were cured by ichthyol. There is one thing, however, connected with the drug which we do not quite understand, *viz.*, the alleged necessity, especially in rheumatism, to take the drug internally simultaneously with its external application.

We had an interview some little time ago with Captain Rühn, who is one of the firm of the ichthyol company, and who volunteered some interesting points concerning the discovery of the drug. Schroeder, a chemist of Hamburg, was sent by several merchants of Hamburg to Styria, in order to ascertain the nature and products of certain mines which these merchants intended to buy there. He accidentally discovered in this visit a curious stone, which, on a closer examination, revealed its descendency from antediluvian fish deposits. Chemical treatment of this stone gave in time birth to the product which we call ichthyol. Profs. Schotten and Baumann vouch for the absolute harmlessness of the remedy.

We learn that an ointment, an oleate, a soap, and various plasters have likewise been prepared from ichthyol.

### Notes and Queries.

---

#### NOTES FROM THE CLINIC OF PROF. J. M. DA COSTA AT THE PENNSYLVANIA HOSPITAL.

*Aneurism of the Aorta relieved by Iodide of Potassium.*—This woman has been in the hospital for some time; when she first came in she complained of a small throbbing lump situated in the episternal notch, and which was very painful. She had first noticed this lump about two years ago, and while it has been growing larger, its course has been somewhat variable, for at times it has seemed to diminish to the size that it was when originally noticed. She has had, during this time, very frequent attacks of dyspnœa and palpitation; in fact, she says that she has rarely been free from these conditions. She has also been troubled with cough, and, at times, has had some difficulty in swallowing. Her appetite has always been fair, her bowels normal, and there is nothing wrong to be noted about her urinary function or apparatus. Her eyesight and hearing are both good. She cannot lie on her left side, but can usually derive relief from the dyspnœa by lying on her back. The cough which she has is somewhat croupy in character and is worse at times. She is now better in reference to the inability to lie on her left side, and can assume various positions without so much discomfort. There is a great deal of pain about this tumor, and recently the glands in its vicinity have become enlarged. She suffers also from vertigo, and says that she every now and then takes cold, when all her symptoms become aggravated;

at these times she will suffer from nausea, but has never had any œdema. The main symptoms, then, in this case, are a pulsating tumor, just above the sternum and a little to the right of the median line, associated with dyspnœa, and at times quite severe attacks of vertigo. At present all the symptoms are much better than when she came in, so far as their urgency goes, though we can still plainly see the tumor, which, however, is smaller than it was at the time of admission, the dyspnœa is scarcely complained of, and the vertigo not at all. When she came in the signs of an aneurism were obvious,—it could be nothing else,—and we have the gratification of knowing that it has clearly diminished in size. Dr. Da Costa states that he never had any doubt about the diagnosis. As regards the condition of the pulse, a very perceptible difference may be noted: the right is much stronger than the left, this fact being noted in the temporal as well as in the radial artery. There is, apparently, no difference in the pupils, but this woman has those eyes where it would be a difficult matter to note any very slight disparity. The heart is not increased in size, and there is no murmur. The respiratory murmur is good in both lungs, though it is rather feeblor on the right than on the left. The pulsation at the notch of the sternum is still present, but it is only moderate, and when the stethoscope is placed over it no murmur is heard, but there is a long, loud, wavy first sound, produced by the expansion of the sac, followed by a short second sound. The glands about the neck are still enlarged, more markedly so on the right and but little on the left, though some time ago they were very plainly enlarged on the left. No murmur can be heard in the right carotid, and it never was present. Now, there can be no doubt about the diagnosis; when we consider the presence of a pulsating tumor, croupy cough, pain, a wavy first sound, dyspnœa, they all indicate a pressure on some nerve, most likely the inferior laryngeal nerve. Often, in such cases, the use of the laryngoscope will aid in the diagnosis, for occasionally one vocal cord will be paralyzed from this pressure, while the other will be normal. Just now all the symptoms are better, but there is no doubt that we have to do with an aneurism, and there is also no doubt as to its location: it is surely located in the arch of the aorta. There is no doubt either that it has markedly decreased in size. It is obvious that you should be very careful in making a diagnosis in such a case, for an error might be fatal. If, in connection

with the enlarged condition of the glands, you were to mistake this pulsating tumor for a scrofulous gland and plunge a bistoury into it, the result would not be very satisfactory. This improvement has taken place under the free use of iodide of potassium. This woman has had 15 grains thrice daily, which is a very full dosage for her, because every now and then frontal headache and coryza will demonstrate that she possesses an unusual susceptibility to the drug, and its use must then be intermitted. She has been on this treatment since the 19th of January, and has had nothing else, save a little morphine, when the pain was very severe, and iodide of cadmium ointment to the enlarged glands. She has had no particular diet, and nothing special has been done for the cough or dyspnoea, save a little morphine and atropine at first, when the cough was very severe and irritating. Now, Dr. Da Costa thinks that the blood is clotting in the sac of this aneurism, and if this process goes on there will be a complete cure. You will seldom see a cure where the benefit to be derived from the iodide of potassium is so very marked. Dr. Da Costa thinks that the only treatment really worth anything is that by the use of *full* doses of iodide of potassium and a moderate diet, rather under- than over-feeding the patient, and absolute rest in bed. This latter injunction is very important, for we would not have had such good results in this case if the patient had been allowed to be up and about.

#### REMARKABLE TENACITY OF LIFE.

To the Editors of the THERAPEUTIC GAZETTE:

GENTLEMEN:—A most remarkable case, showing the tenacity of human life, has occurred in my practice, an account of which may, perhaps, benefit the profession.

On the morning of the 16th of March I was summoned as coroner to the inquest of a child in the vault of the water-closet adjacent to one of the hotels of this town. It had been there on the frozen excrement about two hours. It had been thrown forcibly by the mother down the hole, and then pushed out of sight under the flow with a broom-handle, so that nothing but the hand and wrist were to be seen. With a pair of blacksmith's tongs the hand was grasped and the child removed. It was pale, cadaveric, cold, motionless, with about one foot of cord attached to the umbilicus. I called for a bucket of hot water and immersed the child, also using artificial respiration. After a few minutes noticed a

gasp. I removed the child to a warm room in the hotel, and used friction, artificial respiration, and immersions in hot water alternately, and in about an hour the body was fully restored to life, a fine boy of nine pounds, and perfect with the exception of an abrasion on the back and the contusion of the hand made by the tongs in extrication from the vault. As soon as life began to manifest itself blood began to ooze from the cord, which I tied properly.

The mother after her delivery, which occurred on the floor of the water-closet, cleaned up the floor with a mop and went to bed, stating she was sick. She was removed to a home over a half-mile distant, when the after-birth came of its own power. I hunted her up in the afternoon, when the particulars were made known. The girl is 20 years old, unmarried, and will not take her offspring. Mother and child doing well at present.

GEORGE ROBERTS, M.D.

CREIGHTON, NEB.

#### VINUM COCÆ.

The *Fortschrift* of January 5, 1886, gives the following prescription for the wine of coca: Take 30 grammes of foliæ cocæ and moisten the same with diluted alcohol, and add 1 litre of wine (Muscat, sherry, or Malaga). A better and quicker way is, if instead of the coca-leaves the corresponding quantity of the fluid extract—*i.e.*, 30 grammes pro litre of wine—is taken.

#### QUININE IN CHRONIC DYSENTERY.

The following case, reported to us by DR. CHEVES BEVILL, of Winfield, Ark., may be of interest to some of our readers:

R. P., aged 55, a very stout man, had typhoid fever some ten years ago, and has suffered ever since, more or less, with his bowels, and especially for the last three years, from severe chronic dysentery, with griping and bloody stools. He had been treated by five or six physicians, and no one seemed to do any good. The different astringents, such as acetate of lead, sulphate of zinc, sulphuric acid, creasote, nux vomica, opium, and pernitrate of iron were employed. Fluid extract of ergot and paregoric did him a great deal of good for two or three months, while using it, but it failed at last, and he was getting into such a state that there seemed no chance for him to live much longer. At

this time he began to have chills and fever, and Dr. Bevill was called to see him. He was extremely weak. Quinine was given in large doses, and morphine sul., gr.  $\frac{3}{8}$  to  $\frac{1}{4}$  with the dose, to ease the griping pains. He was kept on this treatment for three or four weeks. This was in September and October last; and since the 10th of October he has had only two bloody stools. He lives in a malarious region, but had no chills until September last for years. He now is healthy, can eat anything he wants. Dr. Bevill is sure it was the quinine that cured him. If some, or any, of our readers know of such cases being benefited by such treatment, it is to be hoped they will report them.

#### CHILDBIRTH DURING AN ATTACK OF SMALLPOX. THE INFANT NOT INFECTED.

DR. R. J. BANNING writes to the *British Med. Journ.*, February 20, 1886, an account of a case in which a woman, during the height of a tolerably severe attack of confluent smallpox, gave birth to an infant perfectly uninfected. The baby was vaccinated within a few hours after birth and successfully, both mother and child doing well. This fact is not in accordance with the general opinion that a child born during a developed attack of smallpox in the mother must necessarily be infected.

#### ON THE TOXIC NATURE OF IVY.

DR. AL. JANDOUIS having learned of several fatal accidents produced in children by the eating of berries of *hedera helix*, the ordinary ivy, examined this plant, and records his results in the *Deutsche Medizinische Wochenschrift* of February 8, 1886. Pliny long ago spoke of its toxic nature, and Matthioli praised its emmenagogue virtues.

The berries were found to contain sixty per cent. of pulp and forty per cent. of semen. The former consists of a dark red pigment colored green by ammonia and hydrochloric acid, of grape-sugar, gum, and a resin, which constitutes an amorphous green-yellowish powder, having at first a sweetish, then a sharp, pungent taste; there exist also albumen, fibrin, water, and mineral matters in the pulp. The semen consists of a fatty oil, albuminous matters, and a peculiar substance of an acrid and astringent taste, almost insoluble in water, mineral matters, and water. Of all these constituents the resin in the pulp

and the astringent substance of the seed can alone be regarded as poisonous elements, and to their combined action the toxic character of ivy is to be attributed.

#### PYRIDIN IN ASTHMA.

DR. JOSEPH S. NEFF (*New York Med. Journ.*, March 13, 1886) has followed the example set by Sée, already published in the columns of the *GAZETTE*, in treating asthma by inhalations of pyridin. Dr. Neff used from one-half to one drachm poured upon a saucer placed in one end of a small room, with doors and windows closed, or, what is better still, a large closet, and allowed patients sitting a little distance from it to inhale vapors mixed with the air. The absorption is immediate, the drug being detected in the urine in a few moments.

Upon the healthy adult, as shown in himself, assistants, and nurses, there was almost universally a flushing of the face, with quickening of the pulse and respiration, the latter lasting but a few moments, the former from fifteen minutes to ten hours, depending largely upon the length of time of inhalation. In several instances temporal headache of a slight character persisted for several hours; at times a peculiar full sensation approaching giddiness is experienced.

The fact that in the healthy the pulse and respiration are quickened for a few minutes does not hold good in asthmatic patients, for, almost without exception, the heart's action, which previously may have been accelerated, slowly falls to the normal, without change in character or rhythm; and less rapidly the respirations, which become slower, easier, and more full, the intense longing for air disappearing, with diminution of the oppression.

In most cases there is a desire to sleep, which in some becomes irresistible; this resembles, however, normal sleep, from which patients are easily aroused, and without insensibility or loss of intelligence, thus distinguishing it from the sleep produced by narcotics and anæsthetics, although there is a slight loss of muscular reflex action.

Dr. Neff used this preparation many times in a series of twelve cases of asthma. The following represents a summary of his results:

Four were females, eight were males; the ages ranged from twenty-six to sixty-five, divided as follows:

Nervous pulmonary asthma, three. No return of attacks in any.

Cardiac asthma, three. All were relieved of attacks. One remained under observation three months, and one for two weeks only.

Bronchial asthma, three. In one there was no return during ten weeks' stay in the hospital. The two others were relieved of their attacks and insisted upon their discharge, being under treatment less than three weeks.

Asthma in advanced phthisis, two. In one there was but slight relief during the paroxysm; in the other there was absolutely no benefit.

Asthma as a complication of gout, one. No return in a month. Albuminuria from interstitial nephritis was present.

Of the fourteen cases reported by Sée, four were in females, ten in males, from thirty to sixty-eight years of age. Nine were what he terms "pure asthma," all of which were more or less relieved, and five cases of cardiac asthma.

In one case of twelve years' duration pyridin caused nausea and vertigo after eight days of treatment, which necessitated its discontinuance, although great relief was obtained. Nausea Dr. Neff has not seen; vertigo but once.

In one or two cases where the expectoration had been purulent it lost that character after the inhalation.

All unpleasant symptoms seem to be confined to cases with long-standing emphysema, or valvular or degenerative heart-disease, with small, irregular pulse. In young, robust people with "simple" pulmonary asthma there seems to be drowsiness alone.

The beneficial results obtained from this remedy seem to be from its action on the sympathetic and the medulla.

Any depressing effects on the heart would seem due rather to the interference with the pulmonary functions, death being caused, in the lower animals at least, by paralysis of the respiratory centres.

Pyridin is not to be classed as a curative agent. Most likely its greatest value will be seen in cases of simple or nervous pulmonary asthma, when the iodine preparations cannot be borne, or nitro-glycerin and sodium nitrite are contraindicated. Although in the bronchial or catarrhal forms of the disease the relief of the paroxysms has been marked in ninety per cent. of the cases treated, of the remaining number nearly all had emphysema of long standing.

In asthma occurring in advanced phthisis the drug should be given with care on account of the small amount of lung-tissue left unaf-

ected, especially where there is a great degree of consolidation with fibroid induration, when, perchance, the spasm may be relieved, but few air-vesicles remain in condition to respond. Here at least morphine will hardly be superseded.

In phthisis the recurring dyspnoea and orthopnoea are relieved during the period of inhalation only, returning in a few moments, and at times with increased violence.

With so little experience, this drug must be administered with a certain degree of caution until its action is thoroughly understood, severe or persistent headache, nausea, vomiting, and vertigo acting as danger-signals, warning us to proceed with care.

#### THE VITALITY OF CHOLERA BACILLI.

GUTTMANN and NEUMANN publish in the *Centralblatt für die Med. Wiss.* of February 13, 1886, some of their observations made on the vitality of cholera bacilli. They found the vital duration of these pathogenetic microbes relatively very high. Bacilli cultured on "agar-agar" were, after the expiration of two hundred and nineteen days, found still living, and capable of propagation, and those planted on peptone-gelatin showed equal signs of life after two hundred and nineteen days. From the former it was even possible to secure pure cultures capable of causing infection.

#### ARTIFICIAL MILK.

It is a curious fact that when a fat is boiled with caustic potash in the relation of fifty parts of alkali to one hundred parts of fat, it is gradually dissolved: the glycerin, however, is not set free. If the alkaline solution is now acidified, the original fat will be regained; but it will have new properties. It is now soluble in alcohol, and when added to ordinary fats, even in very small amounts, it imparts to them the property of forming complete emulsions with extraordinary dilute solutions of the alkaline carbonates. In order to make a liquid which shall possess the appearance and the most important chemical properties of milk, Chichkoff proceeds as follows. Some of the modified fat is added to ordinary fat, and the mixture emulsified with a dilute solution of potassium or sodium carbonate. Calcium and magnesium phosphates are then added in the form of powders, and also a certain amount of casein which has been rubbed up with a little ammonia. Another

solution is now made by dissolving milk-sugar in dilute hydrochloric acid and adding a solution of albumen. The two liquids are now cautiously mixed, the acid liquid being poured into the alkaline one, and the mixture well stirred after each addition. This artificial milk does not contain the ferment occurring in natural milk, but if a little sour milk is added to it, a thick layer of cream soon rises which possesses all the properties of real cream and can be worked into butter. The artificial milk also curdles and forms whey. The taste of the milk, however, is not quite as palatable as it might be; but this may be improved by further experimenting. This peculiar power of the modified fat to form emulsions may be of use in pharmacy.—*Druggists Circular.*

#### A NEW NARCOTIC AND MYDRIATIC.

According to a note appearing in the *Deutsche Med. Wochenschrift* of February 8, 1886, PETIT, of Paris, examined the rind of *Bowdichia major* (*sehipira major*), which, in Brazil, is used by the natives as a febrifuge, and found it to contain an alkaloid, which, in doses of  $\frac{1}{4}$ -grain in frogs and in 1-grain doses in guinea-pigs, showed distinct narcotic properties. In the latter animals the alkaloid causes also convulsions. Besides being a narcotic the drug evinced also powerful mydriatic properties.

#### ON THE POSITION IN NUTRITION OF THE VARIOUS CLASSES OF FOOD-STUFFS.

In no department of science, perhaps, has more energy been shown than in the inquiry as to the part played by the various classes of food-stuffs in the animal economy. Nowhere has the evolution of ideas and theories followed more rapidly its course, thanks to the indefatigable zeal of the workers in this branch. Liebig was one of those who did much to place the subject on a scientific basis, and by the contribution of carefully ascertained facts to give the whole research a stimulus to which we are largely indebted for the progress accomplished. We have had to modify, it is true, his views on the correlation of exercise and the excretion of urea; and the altered views materially influence the theory of nutrition. The opinion formerly entertained that urea represented the wear and tear of the tissues of the body, and therefore bore a constant relation to the work done by them, has to be abandoned. The

albuminoid constituents of the tissues are in such a condition of stability, that they do not themselves readily undergo metabolism in conditions of health; and it is only under the influence of an acceleration of metabolism on the one hand, or a diminished supply of albuminoids on the other, that they are decomposed. That portion of the albuminoid constituents of the food which circulates with the blood is more easily split up; and, as the activity of the cellular elements in effecting these changes is to some extent dependent on the amount of this "circulating albumen," so the excretion of urea will correspond to some extent to the amount of nitrogenous material taken in with the food. There is, however, for every individual a limit to the activity of his cellular elements, and if this be surpassed, metabolism will be diminished and oxidation only imperfectly performed. Hence a liberal nitrogenous diet does not, of itself, tend to an increase of body-weight or strength.

Contrary to the behavior of the albumens in the organism, the extent of fatty metabolism is independent of the ingestion of fat, but is markedly affected by the amount of work performed by the organism, and by the maintenance of bodily heat. The material effects of albumen and fat in the system are in a certain sense opposed, for the former increases the tissue-waste, and secondarily the oxidation, while fat induces the opposite effects. This action of fat is of special importance, when we have to consider how best to attain an increase of the constituents of the body. With an exclusive supply of albumen, only very small quantities of this substance can ever be retained in the body; for each accession of albumen to the food gives rise to an increase of waste, until, after a few days, the balance between income and expenditure is again established. With a simultaneous administration of albumen and fat a less amount of albumen is on this account necessary to meet the material wants of the organism, and if it be present in excess the metabolic processes do not attain the same proportions as with a diet consisting exclusively of albumen, so that a larger proportion of the excess remains undecomposed in the body and adds to its weight. The fat stored in the body acts in like manner with the fat contained in the food, since it likewise lessens the waste of tissue and secondarily the oxidation. This is the reason why corpulent individuals frequently continue to gain in bulk, although they are not in the habit of indulging immoderately in food. The action of carbohydrates

resembles that of fat in protecting from metabolism a certain amount of the circulating albumen; and if given in excess they will, in consequence of the greater facility with which they undergo metabolism, lead to the more hardly metabolizable fat being left unchanged and deposited in the tissues. From this we may conclude that the generally assumed transformation of carbohydrates into fat does not take place.

As already stated, an increase in the nitrogenous substances in the blood leads to increased metabolism, and at the same time the amount of "circulating albumen" is augmented. This explains why a highly-fed animal can better withstand privation than one more poorly nourished, since it is only after several days that the stock of circulating albumen will become exhausted, and the organism is forced to draw on its own tissues for nitrogenous material. Let us take an animal fed on a quantity of albuminoids insufficient for its needs, it will then have to draw upon its own tissues to make up the deficiency. If some fat be added, a part of the albumen is economized, and the amount of nitrogenous waste, as shown by the urea excreted, is lessened; so that in a well-fed animal starvation provokes a diminution, but in a poorly-fed animal an augmentation of nitrogenous metabolism. Similarly alcohol, in consequence of its metabolism and of its fat-sparing action, behaves in the character of a food. The main value of stimulants is, however, more in the direction of slowing metabolism and so lessening waste, than from any nutritive qualities which they may possess. Most of them, moreover, have an influence on the process of digestion which in certain cases may, by rendering it slower, conduce to more perfect assimilation.—*British Medical Journal*, February 13, 1886.

#### TWENTY-NINE CASES OF TRACHEOTOMY OF A PRIVATE PRACTITIONER.

BUCHHOLTZ, in a recent inaugural essay (Berlin, December, 1885, Niethe, p. 28), reports the results of twenty-nine cases of tracheotomy performed in private practice against croup and diphtheria. The number of lives saved out of these twenty-nine was twelve. This is a very good showing, and a welcome communication from the usually rather neglected statistics of the private practice in a small town (Kottbus, Prussia). We have here another proof that even under the most unfavorable circumstances the results of

tracheotomy are more favorable in the private house than in the hospital.

#### TUMBEKI: A PERSIAN NARCOTIC.

In the consular reports from Trebizond, for some years past, mention has been made of a vegetable product, "tumbeki," occurring in the same list as tobacco, and evidently an article of regular commerce between Persia and Turkey. Quite recently also, in an interesting article in *Harper's Magazine* on "The Domestic and Court Customs of Persia," tumbeki is referred to as a species of tobacco in high repute in Persia, which, owing to its remarkable narcotic properties, is always smoked in a water-pipe. In order to obtain more definite information with regard to tumbeki, and the importance of its narcotic and possible medicinal properties, Mr. E. M. Holmes, the curator of the Museum of the Pharmaceutical Society, has entered into correspondence with consular and other authorities upon the subject; and the results were embodied in a communication made at an evening meeting of the Pharmaceutical Society on Wednesday, February 10. Mr. Holmes found the authorities somewhat at variance as to whether tumbeki is the product of *Nicotiana rustica* or *N. persica*; but leaves, which he received as tumbeki from Trebizond and Constantinople, both correspond in character with *N. persica*, the stem-leaves of which are sessile, whilst *N. rustica* has stalked cordate leaves. It appears, further, that there are three qualities of tumbeki,—the Shiraz, Kechan, and Teheran,—all derived from the same plant, though the value of the first is double that of the last two. In order to test the accuracy of the statement that tumbeki contains more nicotine than tobacco-leaves (*N. tabacum*), portions of four samples were submitted to analysis by Messrs. Eastes and Ince. After trying various processes for the estimation of the nicotine, they arrived at the conclusion that the most reliable method consisted in preparing an extract of the leaves with dilute sulphuric acid, removing albuminous matters from the extract, and precipitating the alkaloid with a standard solution of Mayer's reagent (a mixture of mercuric chloride and potassic iodide). By this method, they obtained results corresponding to the following average percentages of nicotine: Shiraz, 5.835 per cent.; Ispahan, 5.4945 per cent.; Hidjaz, 2.046 per cent.; and Kechan, 2.90925 per cent. In further analysis of the leaves, the authors found the extractive matter to range from forty per cent. in the Kechan

to fifty-five per cent. in the Shiraz sample; the saccharine matter to be highest in the Kechan sample, whilst the ash was about twenty-five per cent. in all the samples.—*British Med. Journ.*, February 27, 1886.

#### A SPECIMEN OF A GERMAN MIXTURE.

The balsam de Bori, up to rather recent times not infrequently prescribed by heroic German physicians, is truly a little pharmacopœia by itself, and unquestionably also a good thing—for the apothecary. The prescription for the balsam reads as follows:

R Tinct. angelic.,  
Tinct. aloes,  
Tinct. myrrhæ,  
Tinct. benz., aa ℥vii;  
Ol. lavendulæ, gtt. ii;  
Bals. Peruv., ℥iii;  
Stor. calam.,  
Olib. pulv., aa ℥i.

Fiat mistura, digere secundum artem et filtra.—Bon appetit!

#### VESICATING INSECTS.

The wings of vesicating insects possess a singular softness of the elytra and the integument, differing from that of other insect tribes. The explanation of this fact is found in the histological, and not on the chemical, characters of the wing, as was at one time supposed. Between the two layers, which are connected at their edges by chitin, there is a considerable space, and the two layers are connected by chitinous pillars, which, although thin and delicate, form substantial supports. In most other insects the chitinous layers are much thicker, the pillars more numerous, and the spaces are almost obliterated. The peculiarities noted have, it is believed, much to do with the irritation produced by minute particles of wings when applied to the skin of human beings.—*Medical Press*, January 13, 1886.

#### THE MEDICAL USE OF SACCHARINE.

At the meeting of the Manchester Medical Society, held February, 1886, DR. DRESCHFELD (*Brit. Med. Journ.*, March 13, 1886) showed some preparations, and spoke of the therapeutic uses of this new sweet compound (benzoic sulphinide, or anhydro-ortho-sulphamin benzoic acid) obtained from coal-tar. This body was prepared by Dr. Fahlberg, of New York, and its physiological properties had been recently studied by Stutzer and

Mosso. Saccharine was a white powder, of acid reaction, soluble in 500 parts of distilled water, and a little more soluble in alcohol and ether. It was intensely sweet, and a dilution of 1 in 10,000 had still a very sweet taste, very much like that of sugar, together with a peculiar by-taste like bitter almonds (solution of sugar lost its sweetness in a dilution of 1 in 250). Saccharine, when given internally or subcutaneously, was exuded completely by the urine in an unaltered state; it was, therefore, not decomposed in the body. Neither the saliva nor the fæces contained any traces, even after large doses. It had scarcely any retarding effect on the digestion of either proteids or hydrocarbons; in fact, given in small quantities, it increased the diastatic action of malt in the presence of sugar. It had no injurious effect if given even in large quantities (2 to 5 grammes) in man, and produced no appreciable alteration in the appetite. The urine showed no alteration during its administration either in specific gravity or quantity. The urea and sulphuric acid in the urine did not show any changes. The urine had, however, an intensely sweet taste, and did not undergo fermentation readily. Saccharine was slightly antiseptic. Beyond being a substitute for sugar, it possessed no therapeutic properties, except that, in two cases of acid dyspepsia, it relieved some of the troublesome symptoms. Its use was indicated in diabetes and obesity. In diabetic patients, it had no effect either on the quantity of urine or on the amount of sugar passed.

#### A CASE OF POISONING WITH STEINER'S VERMIN-KILLER.

At the seventh meeting of the Medico-Chirurgical Society of Edinburgh for this year, DR. ALLAN GRAY read a paper on "A Case of Strychnine-Poisoning, with an Analysis of Steiner's Vermin-Killer." In the case on which the communication was based there was a remarkable delay of the fatal result for three or four hours. The patient was alcoholic, and had been imbibing freely previous to the suicidal act, which consisted in the swallowing of the contents of a packet of Steiner's vermin-killer. Dr. Gray thought that possibly the presence of the alcohol was sufficient explanation of the slow advance of the symptoms. He then explained the method of analysis followed, laying stress on the sulphuric acid and bichromate of potassium test for strychnine. Appended to the paper

was a comparative analysis of the different vermin-killers.

DR. FOULIS showed scrapings from a wall-paper containing a large proportion of arsenic, and dwelt on the great danger accruing to the too easy possibility of obtaining such poisons. Some discussion followed as to the cause of the delay in the fatal result.

DR. PHILIP asked if Dr. Gray was prepared to place implicit confidence in the sulphuric acid and bichromate of potassium test for strychnine, and if the purely chemical tests should not always be supplemented by the physiological. He referred to a curious case, where the first verdict of poisoning by strychnine had been overthrown through the absence of the evidence afforded by these latter.

DR. GRAY thought the chemical tests often failed through the fault of the chemist.—*Medical Press*, March 10, 1886.

#### THE INTERNAL ADMINISTRATION OF ANTISEPTICS.

The administration of antiseptic drugs, either as prophylactics or as remedies, has been frequently resorted to in the treatment of infective diseases, but not hitherto with an amount of success which has encouraged the profession at large to adopt the method. Some experiments, however, which Dr. Theodore Cash is now conducting for the Local Government Board, appear to justify the hope that this line of treatment may eventually be useful. In a communication recently made to the Physiological Society, he stated that he had been led to test the influence of perchloride of mercury, because it was retained in the body for some days after its administration had ceased, and because it was still a powerful germicide even when very greatly diluted. He found, in an experiment on a rabbit, that, after a quantity of perchloride of mercury, equal to about 8 milligrammes per kilogramme of body-weight, had been injected hypodermically, in divided and highly diluted doses in the course of seven days, the animal only suffered a passing disorder after inoculation with a virus of anthrax which killed another rabbit in forty-four hours. The animal, moreover, was found to be protected against further inoculations with virulent anthrax. A smaller dose (equal to about 5 milligrammes per kilogramme of body-weight) was found to delay, but not to prevent, the onset of the disease. The number of bacilli found in the blood after death in such a case

was very small, but it was found that their virulence had not been diminished, the blood of the animal producing an unmitigated and unmodified attack of anthrax in other animals.—*British Med. Journ.*, February 13, 1886.

#### THE PRESERVATION OF SALICYLATE OF SODIUM.

Salicylate of sodium belongs to the class of preparations which undergo change in time. If salicylate of sodium, either in crystals or in powder, is exposed in a glass vessel to the light, in four to six weeks the exposed portions become darker, and lose their faintly acid reaction, and when dissolved form a dark solution, while the portions protected from light remain colorless, and retain an acid reaction. Salicylate of sodium is also particularly susceptible to the action of moisture. Salicylate of sodium perfectly dry and kept in glass away from the light remains unaltered, while another portion kept in paper at the same temperature soon becomes useless, lumpy, and gray. It seems, therefore, necessary to protect salicylate of sodium from light and moisture. It has also been noticed that the character of the water in which the solution has been made is of influence in the permanence of the solution. When spring water is used, a solution of salicylate of sodium will become brown in a few hours, while it remains colorless when distilled water is used.—*Pharm. Centralhalle*, January 7, 1886.

#### CONVULSIONS IN AN INFANT CURED BY MORPHINE.

DR. H. PLUMMER, of Harrodsburg, Ky., reports in the *Medical Record* for March 27, 1886, the case of an infant, 22 months old, who was seized after a short period of malaise with convulsions. She was seen after the second convulsion, and did not then appear to be very ill, but was fretful. The temperature was 102° and there was some little cough, but there were no signs of pneumonic trouble. Bromide of potassium in 5-grain doses was given every hour, but the convulsions increased in severity and frequency. The bowels had been moved by calomel and castor oil. In the afternoon of the second day the child was in the following condition: The tongue was protruded between the teeth, swollen, and constantly in motion; the forearms were flexed and rigid, the thumbs being firmly drawn into the palms, and the lower

extremities were likewise rigid. The child was now unable to swallow, and the pupils were widely dilated. The convulsive attacks recurred at such short intervals that they seemed to be continuous. Other remedies having proved ineffectual, Dr. Plummer determined to employ morphine, and accordingly gave  $\frac{1}{6}$  grain hypodermically. In a few minutes the little patient fell into a sleep, in which she remained, awaking only to drink, for twenty hours. The pupils became of nearly the normal size, and the muscular system became relaxed. From this time she continued to improve, although she seemed nervous and fretful for a time, and the convulsions did not return.

*A NEW METHOD OF KEEPING PERFORATION OF THE MEMBRANA TYMPANI OPEN.*

DR. McKEOWN (Belfast), at a recent meeting of the Academy of Medicine in Ireland, described a method of making an artificial perforation of the membrana tympani, which would remain open for a period varying from two weeks to two months (*Medical Press*, March 10, 1886). He made a triangular flap of the membrane, commonly selecting either that part in front of or that behind the handle of the malleus. He used a speculum, and illuminated the membrane by the frontal mirror. He then introduced the knife,—a very fine straight knife with thin handle,—punctured the membrane in front of or behind top of handle of malleus, cut upwards as far as he could; then he made a second incision, beginning below, either at anterior or posterior part of membrane, as the case might be, and in a horizontal line with lower end of first incision, and cut upward until the two incisions joined. The flap thus formed, unless in case of very thickened membrane, fell down, or might be turned down with a fine probe, and commonly remained in position, adhering to the membrane below by blood exuded from the cut surface. He had operated on a considerable number of cases, some of long standing, and he gave particulars of some of the most interesting. The ordinary incisions hitherto practised, except to discharge products of inflammation, were of no therapeutic use whatever. The operation proposed was not for the purpose of making an artificial way for the waves of sound, but to give rest to the ear for a long period, and to induce a nervous and vascular equilibrium favorable to the absorption of

deposits and restoration of function. Most troublesome obstructions of Eustachian tubes of long standing had given way to this treatment alone. As to relief of tension in old cases, a simple incision, closing in a day or two, could do no good, but an opening for a period of two weeks to two months might do a great deal. Time was the very essence of the question from a therapeutic point of view. He illustrated the use of the method in diagnosis, and also in opening a way for efficient treatment of some cases of hypertrophic change of the lining of the middle ear. So far as he could follow his cases he found none were made worse, some were not benefited, but the majority were relieved in a greater or less degree, some to a remarkable extent. According to authorities, after certain operations on the middle ear a relapse or even an aggravation followed; but after this method, in which the fundamental points were a large opening, no destruction of tissue, and the avoidance, as a rule, of all irritation, the improvement had been found sometimes to become even greater after the perforation had closed for some time.

*THE MODE OF ADMINISTRATION OF SPARTEINE.*

We have already published abstracts of the papers of various authors as to the use and physiological action of this new cardiac remedy. M. HOUDE publishes the two following formulæ in the *Journ. de Med.*, January, 1886, for the administration of this drug: Sulphate of sparteine,  $7\frac{1}{2}$  grains; milk-sugar, 75 grains; simple syrup, q.s. M. Div. in pill No. 50. S.—Two to ten of these pills may be given daily, according to indications; each pill contains  $\frac{15}{100}$  grain. Or, sulphate of sparteine,  $4\frac{1}{2}$  grains; distilled water, 32 minims; syrup of bitter orange-peel, 10 ounces. M. S.—Three teaspoonfuls of this syrup are about equivalent to two of the pills made under the preceding formula.

*VIBURNUM PRUNIFLORIUM IN ABORTION.*

DR. W. MACFIE CAMPBELL states in the *Brit. Med. Journ.*, February 27, 1886, that he has had an opportunity of testing the use of viburnum pruniflorum in several cases of habitual miscarriage, and can entirely endorse the good opinion which is generally held as to its value; and he reports six cases in five of which the administration of 3 grains of the solid extract three times a day served to prevent threatened miscarriage.

### THE PHYSIOLOGICAL AND THERAPEUTIC ACTION OF HYDRASTINE.

BY THOS. J. MAYS, M.D.

**H**YDRASTIS CANADENSIS, or golden seal, as it is commonly called, has been long and favorably known and used by the eclectic practitioners of this country. It is claimed by them, and with good reason too, that it exerts a powerful tonic influence upon the mucous surface of the alimentary canal, nasal passages, etc., when administered internally, and externally it has proven itself an

excellent remedy in chronic mucous inflammations of the eye, mouth, bladder, etc.

In 1851, Mr. A. B. Durand discovered a powerful alkaloid in the plant, which was further investigated by Mr. F. Mahla, of Chicago, and which is now called hydrastine. Dr. King,\* the ablest exponent of that school of medicine, attributes the therapeutic action of the plant to this alkaloid. The latter has recently received a good deal of attention from various experimental physiologists, with the desirable result of placing its action on a very intelligent basis. Thus, Slavatinski ("Ueber die Pharmakologische Wirkung des Hydrastins," *Med. Obosrenje*, November 16,

\* American Dispensatory, p. 432.

1884, p. 346) found that the subcutaneous injection of 1 to 2 mg. produces disturbance of co-ordination, diminution of reflex action and of the pulse, and acceleration of respiration in the frog. In doses from 6 to 10 mg. it gave rise to transient spasm, complete paralysis, and diastolic arrest of the heart. The irritability of the motor nerves was enhanced, while that of the sensory nerves was depressed. In mammals he saw no alteration in the blood-pressure.

Dr. Fellner (*Centralblatt für die Med. Wissenschaften*, November 24, 1884, p. 417) details in a condensed form the physiological results which he obtained from the subcutaneous injection of the fluid extract of *hydrastis canadensis*. All the experiments were performed on curarized dogs, and the influence of the drug on the blood-vessels, the heart, the stomach, the small intestines, and the uterus was closely observed. He obtained the following results:

1. Large doses produced a transient rise in the blood-pressure, which was followed by a protracted depression of the same.

2. Medium doses are followed by the same phenomena, only in a less pronounced degree.

3. Small doses produce a very slight diminution of the blood-pressure, which is very soon succeeded by a permanent rise. Repeated injections of medium doses had the same effects as a single large dose, and repeated injections of small doses had the same influence as a single medium dose.

4. Division of the splanchnic nerves did not materially alter the above-described effects of small and medium doses, nor did compression of the abdominal aorta.

5. However, after division of the spinal cord in the neck, it produces no rise in the blood-pressure.

6. During the period when large doses exercise their depressing influence on the circulation, both strychnine and dyspnoea elevate the blood-pressure.

7. During the stage of lowered blood-pressure the alimentary canal becomes hyperæmic, while during the stage of elevated blood-pressure the same becomes pale and anæmic.

8. In the first stage of the action of large and medium doses considerable slowing and occasional cessation of the pulse occurs. Division of the vagi counteracts or entirely prevents this.

9. During the stage of heightened blood-pressure and general vascular contraction the whole uterus undergoes spontaneous contractions.

Dr. Bartholow (Lloyd's "Drugs and Medicines of North America," vol. i. page 156) ascertained that in frogs hydrastine produces stiffness, hyperæsthesia, convulsions, and diastolic arrest of the heart. The same phenomena were produced by it in the rabbit, in which he also observed a slight lowering of the blood-pressure. This author concludes from his experiments that the convulsions are spinal, that it exhausts the irritability of the motor nerves and muscles, and that chloral is probably a physiological antidote to it.

I think the following *résumé* comprises the chief points in the above-given experiments on the action of hydrastine, viz.: That in small doses it elevates and in large doses depresses the blood-pressure; that in small doses it produces contraction and in large doses dilatation of the vascular walls; that through the period of elevated blood-pressure it inhibits cardiac action; that in small doses it produces anæmia, and in large doses hyperæmia of the alimentary surface; that it induces uterine contractions; that it enhances the irritability of the motor and depresses that of the sensory nerves; and that it exercises its control over all these organs through a central and not through a peripheral influence.

While all these experiments cover valuable ground and bring out very clearly various phases of the physiological action of this alkaloid, it seemed very important to develop more definitely whether it acts chiefly on the sensory or on the motor nerves, and with this end in view the following experiments were instituted during June and July, 1885:

*Experiment 1.*—To test the action of hydrastine hydrochlorate on the reflex frog when locally applied, by immersing the right leg at intervals in a three per cent. solution, and by comparing the minimum reflex irritability of both legs by connecting them with a secondary coil of an induction apparatus by means of a commutator.

11.14. No spasms induced in either leg at 0.		

*Experiment 2.*—To test whether the above-shown interference with reflex sensibility is due to a central or peripheral influence. The blood-vessels of the right leg were ligated in the region of the thigh, in order to obviate the general absorption of hydrastine. The right leg was immersed in a one and a half per cent. solution of the salt, and its minimum reflex irritability tested and compared with the opposite leg for some time, after which the left leg was immersed and the effects watched. Reflex frog large. Brain pitthed at 5.15 P.M.

A.M.	Left foot.	Right foot.
6.20. Minimum reflex irritability before immersion.....	12	15
6.23 to 6.26. Immersion of right leg.		
6.27.....	12	11
6.30.....	12	11

7.32 to 7.35. Immersion of left leg.		
7.35.....	10.5	10.0

A.M.	Left foot.	Right foot.
7.42.....	10.0	9
7.43. The slightest touch of the right or ligated leg is sufficient to call forth a spasm, while a number of sharp taps on the left are required to induce the same.		
7.44. Minimum reflex irritability....	9.5	9.5
9.46. Minimum reflex irritability....	9.5	8.5
8.10. No blow or tap, however forcible, on either foot will serve to call forth a spasm. Striking the anterior extremities will quickly induce one.		

This experiment undoubtedly shows that a reduction of sensibility is brought about by a local peripheral action of hydrastine; but that it exerts this influence much more readily and effectively if it is absorbed, and thus allowed to come in direct contact with the spinal centres of sensation.

*Experiment 3.*—To test the action of hydrastine on the reflex sensibility of the frog, when introduced subcutaneously in small doses. Blood-vessels of right leg ligated in region of thigh. Reflex frog small, and prepared at 7.00 P.M.

P.M.	Left foot.	Right foot.
Minimum reflex irritability before injection.....	14	12

9.10. Minimum irritability of both sciatic nerves.....	0	15
9.12. Heart arrested in diastole.		

This experiment shows the same results as those which were yielded by Experiment 2, although brought out by a different method. It demonstrates that hydrastine exerts both a

peripheral and central anæsthesia. A number of other experiments have been made which demonstrate that hydrastine has a decided affinity for sensory nerves, and affects these before it does the motor nerves, and that it exerts a great deal of its influence through the spinal cord and not through the cranial centres; but, in view of the fact that its physiological action has been brought out so well by other observers, I do not deem it necessary to publish these. The results of my experiments on the frog may be summed up as follows:

1. That it produces paralysis in the early stage of poisoning, which is followed by convulsions.

2. That the convulsions are chiefly spinal in their nature.

3. That a stage of hyperæsthesia precedes that of convulsions.

4. That it depresses sensation or blunts sensibility when locally applied.

5. That it affects the posterior before the anterior extremities.

6. That it affects sensation before motion.

7. That it affects the sensory nerves principally from the centre to the periphery, and not *vice versa*.

*On Man.*—My friends Drs. Seiss and Stevenson kindly aided me in ascertaining its physiological action on the human body, at least in so far as its influence on the pulse and on local sensibility is concerned. It was tested both subcutaneously and *per os*,—five times by each method. A copy of the protocol of three experiments with the subcutaneous method reads as follows:

## NO. 1.

P.M.

- 8.44. Pulse 68.
- 8.55. Pulse 68.
- 9.00. Injected 6 minims of one per cent. solution of hydrastine (P. D. & Co.),  $\frac{1}{8}$  grain, in left forearm directly below elbow.
- 9.05. Areola around seat of injection numb.
- 9.10. Pulse 72.
- 9.23. Pulse 72. Red blush around seat of injection.
- 9.25. Numbness over ulnar region of hand and little finger.
- 9.30. Pulse 68.
- 9.37. Pulse 66.
- 9.45. Pulse 64.
- 9.52. Whole arm below seat of injection benumbed to some extent.
- 9.54. Pulse 66.
- 10.00. Arm below seat of injection itching.
- 10.05. Pulse 60.
- 10.15. Pulse 64.
- 10.30. Pulse 60.
- 10.59. Pulse 60.

P.M.

- 11.00. Feels very well. No bad effects except a soreness around seat of injection. Sensation restored throughout the whole arm.
- 11.15. Pulse 60. Very full.

## NO. 2.

P.M.

- 8.44. Pulse 76.
- 8.55. Pulse 76.
- 8.56. Injected 7 minims of one per cent. solution of hydrastine (P. D. & Co.),  $\frac{1}{4}$  grain, in left forearm below elbow-joint.
- 9.05. Small area around seat of puncture perfectly numb. Can push a needle through skin in this neighborhood without producing any pain.
- 9.08. Pulse 76.
- 9.22. Pulse 74. Red blush around seat of injection, which is raised.
- 9.25. Numbness over ulnar region of hand.
- 9.35. Pulse 68.
- 9.45. Pulse 68.
- 9.50. Blush around injection disappearing, but still a little swelling.
- 9.52. Whole arm below seat of injection somewhat benumbed.
- 9.68. Pulse 65.
- 10.10. Pulse 65. Full.
- 10.24. Pulse 65.
- 10.35. Pulse 65.
- 10.54. Pulse 65.
- 10.59. Pulse 65. No bad effects, except pain around seat of injection. Sensation in arm restored.
- 11.15. Pulse 65.

## NO. 3.

P.M.

- 8.44. Pulse 102. Not feeling well, on account of an ephemeral fever due to a slight cold.
  - 8.57. Pulse 102.
  - 9.02. Injected 6 minims of hydrastine (P. D. & Co.),  $\frac{1}{8}$  grain in left forearm.
  - 9.05. Raised areola around injection.
  - 9.10. Pulse 100.
  - 9.15. Pulse 92. Red blush around seat of injection.
  - 9.25. Numbness over ulnar region of hand.
  - 9.30. Pulse 92.
  - 9.35. Pulse 86.
  - 9.45. Pulse 80.
  - 9.52. Whole arm below seat of injection somewhat blunted in sensibility.
  - 9.55. Pulse 86.
  - 10.00. Arm below seat of injection itching.
  - 10.10. Pulse 84.
  - 10.20. Pulse 86.
  - 10.38. Pulse 82.
  - 10.57. Pulse 80. Feel very much better than at beginning of experiment. Sensation in whole arm restored. Sore around seat of injection.
  - 11.15. Pulse is full and strong, and 80 per minute.
- (In no instance was the irritation produced by the puncture of the needle prolonged over twenty-four or forty-eight hours.)

In the following cases it was taken by the mouth:

## NO. IV.

- P.M.  
 8.05. Pulse 78. Two hours after supper.  
 8.10. Pulse 78.  
 8.15. Pulse 78. Took  $2\frac{1}{2}$  grains hydrastine (P. D. & Co.).  
 8.20. Tingling of tongue, as if benumbed.  
 8.25. Pulse 78.  
 8.35. Pulse 78.  
 8.45. Pulse 78.  
 8.55. Pulse 76.  
 9.05. Pulse 76.  
 9.15. Pulse 75.  
 9.25. Pulse 75.  
 9.35. Pulse 74.  
 9.45. Pulse 72.  
 9.55. Pulse 68.  
 10.05. Pulse 70.  
 10.15. Pulse 70.  
 10.25. Pulse 70.  
 10.35. Pulse 70.  
 9.15 A.M. next morning. Pulse 80.

## NO. 5.

- P.M.  
 8.05. Pulse 72.  
 8.10. Pulse 72.  
 8.15. Pulse 72. Took  $1\frac{1}{2}$  grains hydrastine (P. D. & Co.).  
 8.35. Pulse 74.  
 8.45. Pulse 72.  
 8.55. Pulse 72.  
 9.05. Pulse 70.  
 9.15. Pulse 72.  
 9.45. Pulse 66.  
 10.00. Pulse 68. Fuller.  
 10.15. Pulse 68.  
 10.20. Pulse 66.  
 10.30. Pulse 66.

## NO. 6.

- P.M.  
 2.20. Pulse 72.  
 2.30. Pulse 72.  
 2.35. Pulse 72. Took  $\frac{1}{2}$  grain of hydrastine (P. D. & Co.).  
 2.55. Pulse 72.  
 3.10. Pulse 72.  
 3.25. Pulse 70.  
 3.35. Pulse 69.  
 3.50. Pulse 68. Fuller.  
 4.20. Pulse 68.  
 4.22. Took 1 grain more.  
 4.30. Tongue feels slightly numb at tip.  
 4.50. Pulse 64.  
 5.00. Pulse 64. Numbness on tongue gone.  
 5.25. Pulse 61.  
 5.50. Pulse 66.  
 6.05. Pulse 68.

## NO. 7.

- P.M.  
 2.25. Pulse 77. Dinner one and a half hours ago.  
 2.40. Pulse 76.  
 2.45. Pulse 76.  
 2.50. Pulse 76. Took 1 grain of hydrastine (P. D. & Co.).

## P.M.

- 3.05. Pulse 74. Tongue tingles like as if it had cocaine.  
 3.30. Pulse 73.  
 3.40. Pulse 71.  
 4.00. Pulse 71.  
 4.15. Pulse 69.  
 4.45. Pulse 72.  
 5.15. Pulse 65.  
 5.35. Pulse 69.

## NO. 8.

## A.M.

- 9.30. Pulse 80. Took 2 grains hydrastine (P. D. & Co.).  
 10.00. Pulse 70.  
 11.00. Pulse 66.  
 12.00. Pulse 64.  
 12.30. Pulse 64.

*Therapeutic Indications.*—These experiments show that in the healthy organization it has a decided affinity for the circulation,—slows the heart, and in all probability elevates the blood-pressure, and also produces local anæsthesia, therefore confirming the experiments which have been made on the lower animals.

Its influence on the circulation in man is certainly pronounced enough to make itself sufficiently obvious; and, when this fact is coupled with the interesting observation of Dr. Fellner, already cited, that in the lower animals it constricts the capillary circulation to such an extent that it produces anæmia of the mucous surfaces in small doses, it should be a valuable agent in the treatment of all hyperæmic and catarrhal conditions of these organs. Especially is this assumption pertinent when we reflect that it has the power to counteract a relaxed capillary circulation, a condition which, in the great majority of instances, is associated with such hyperæmiæ.

Its anæsthetic action, which is not so striking as that of cocaine or brucine when locally applied, nor so evident as that of theine when subcutaneously introduced, is still remarkable for remaining unobserved so long in an agent which is one of the most popular remedies of the day. It has been used locally to soothe irritable surfaces for more than a quarter of a century, yet the credit of first perceiving its local anæsthetic effect on man in a clinical way belongs to Dr. Charles H. Burnett, Professor of Otology in the Philadelphia Polyclinic, who, but quite recently, called attention to this fact in a contribution to *The Polyclinic* for December, 1885, entitled "Hydrastis with Boric Acid in the Treatment of Otorrhœa."

Dr. Edward T. Jackson, while experimenting with a number of mydriatics a few months ago, was the first to notice that hydrastine dilates the pupil to some extent when applied locally.

Dr. William Rutherford, of Edinburgh, Scotland, in his work on "The Physiological Action of Drugs on the Secretion of the Bile," found hydrastis—a resinous substance prepared from the root of the plant by Keith & Co.—to be a moderately powerful stimulant of the liver.

From what has been said, I think it is evident that hydrastine, on account of the properties which it is shown to possess, is most applicable in catarrhal states of the stomach, bowels, eye, ear, nose, and throat, although it is also indicated in other diseased conditions. A familiar picture to the physician is a combination of the following symptoms: An uneasiness in the gastric region and some eructations after eating, impaired appetite, irregular bowels, coated tongue, bad breath, yellowing conjunctiva, etc. This condition is very much benefited by the administration of hydrastine in  $\frac{1}{8}$  to  $\frac{1}{4}$  grain (Merck) doses before each meal.

The following is a case of gastric catarrh which was relieved by the fluid extract of hydrastis:

J. D. consulted me November 3, 1879, in regard to a pain and swelling in the region of his stomach. His bowels were regular, appetite tolerably good, except when he had pain. Occasionally vomits after a meal, which is always preceded by pain. Vomit very sour. Tongue clean at the tip, but coated at its root. Subject to this disorder for the last three years. Gave him 3 drops of fluid extract of hydrastis canadensis every three hours. Saw patient again November 8, when he felt very much better. Less pain and constriction in stomach, and no vomiting since. He gradually improved, and with the aid of iron and quinine was fully restored.

A similar disorder of the digestive organs is found as a sequel to intermittent fever. A derangement of the stomach and duodenum is one of the most constant concomitants of this disease, and there is little doubt that through its power of relieving this condition, and of stimulating the biliary secretion, hydrastine has earned the reputation of curing "fever and ague." Dr. Brunton, in his work on "Pharmacology, Therapeutics, and Materia Medica," very beautifully explains the rationale of the action of cholagogues in the

treatment of intermittent fever, by eliminating the malarial poison from the portal circulation, and thereby preventing its entrance into the general circulation. Therefore any drug which possesses the power of accelerating the flow of bile often effects a cure, without exercising any direct febrifuge property. A number of years ago I had the opportunity of testing the fluid extract of hydrastis canadensis in intermittent fever, but obtained no results sufficiently positive to warrant the belief that it has any antipyretic virtue.

In studying the action of hydrastine clinically it must always be borne in mind that experimentation shows it to have a powerful action on the spinal nervous system, and hence it should be a most valuable tonic to this portion of the body.

The following case of general enervation, resulting from alcoholic intemperance, is one in which the disorder was due probably to a semi-paralyzed condition of the spinal axis, and in which the beneficial action of hydrastine was well brought out.

CASE.—October 1, 1879. B. M. complains of extreme prostration, diarrhoea, irregular chills, fever, and complete loss of appetite. Very much addicted to alcohol. On examination I found a pulse of very low tension, 100 beats per minute, and pressure along and over the spinal column caused a good deal of pain. He received no benefit from quinine. On the 10th instant his condition was much the same as it was at the beginning of the attack, and the following is a typical sphygmogram of a number which were taken at that time:

From this time on he received 4 drops of the fluid extract of hydrastis canadensis every two hours in water. He began to mend immediately. His appetite improved, bowels became regular, the pain in the spine as well as the chills left him, and he felt better in every way. On the 25th of the same month his pulse was 76 per minute, and I obtained the following sphygmogram, which shows a marked improvement in his circulatory organs:

I think the change that occurred in this patient was principally confined to the vaso-

motor nervous system, and is a strong confirmation of the physiological action of hydrastine on the circulation, as brought out by Fellner in his experiments on animals, as well as by my own on man.

In a future paper I hope to develop more fully the practical aspect of hydrastine, and think I will then have clinical material to show that it is a valuable addition to our materia medica.

In conclusion, I will add that there are many spurious articles of the drug in the market, which are either principally composed of berberine, or contain too large an amount of the yellow coloring matter of the plant. Pure hydrastine is a white crystal, and the finest preparation to my knowledge is the hydrochlorate, manufactured by Merck, and which has been chiefly employed in working out the results of this paper.\*

1716 CHESTNUT STREET, PHILADELPHIA.

### *HAMAMELIS VIRGINICA.*

BY DRs. JOHN MARSHALL AND H. C. WOOD,  
PHILADELPHIA.

**T**HIRTY years ago every American housewife, at least every one in the neighborhood of Philadelphia, gathered the flowers of St. John's wort, soaked them in sweet oil that they might impart their virtues to it, and reverently labelled it "red oil." The red liquid thus obtained was carefully hoarded for the comfort of battered young humanity. A little later than this in the local history of our forefathers, arnica was the sovereign remedy, without which no household could be contented. To bring up a child without arnica was considered almost as hopeless as to bring him up without the Bible or the rod of Solomon. Probably owing to the enterprising, if not praiseworthy, efforts of an American drug firm, the days of arnica have been superseded by those of hamamelis, an herb whose reputation has waxed greater and greater until it has reached even a high point with the medical profession.

The enormous sale and mysterious properties of hamamelis have led us to undertake an investigation of the drug.

Unfortunately, the records of the physio-

logical experiments have been mislaid, and we have been unable to give the exact strength of the preparations used in the experimentations. Some pounds, however, of the powdered drug were allowed to macerate several days in water and then distilled. The first six ounces of the distillate were kept separate and used physiologically.

It will be seen that if the activity of hamamelis depends upon a volatile principle, the distillate which we employed was many times stronger than that sold in the drug-stores. Nevertheless, it was thrown into frogs until they were so full that their skins would hold no more, and the effects produced were no greater and no less than those which would have been caused by injections of similar quantities of distilled water. A single experiment was made upon mammals, with no more positive result, and we must conclude, therefore, that so far as the frog is concerned, and probably also mammals, the watery distillate of hamamelis has precisely the physiological value of water. It may be well to add that the distillate used had a very strong odor of the drug, but a chemical examination showed that it contained only the faintest trace of the volatile oil. In order to test the matter further a complete elaborate analysis of the drug was made, as follows:

Three kilogrammes of the finely-powdered dry root were macerated ten days with 6 litres petroleum ether (boiling-point not over 45° C.). A small portion (2 c.c.) of the resulting extract, in an appropriate vessel, was placed under a bell glass, and a stream of dry carbon dioxide passed over it until the odor of petroleum ether was hardly perceptible. The vessel containing the evaporated extract was then immediately covered and weighed. It was then uncovered and exposed to the air exactly one minute and then weighed. No loss of weight was observed. It was again uncovered and exposed to the air for one minute and weighed, without noticeable loss in weight. From this it was concluded that if a volatile oil were present in the volume (2 c.c.) of extract employed, it was in such small quantity as to be unweighable, therefore a larger volume (100 c.c.) of the petroleum ether extract was employed in the same manner as above described, but no loss of weight was observed.

The remaining quantity (about 4 litres) of petroleum ether extract was allowed to evaporate spontaneously until the odor of the ether was entirely dissipated. The residue possessed the odor which is peculiar to the aqueous and

\*Merck's hydrochlorate of hydrastine is about six times more powerful than Parke, Davis & Co.'s hydrastine, which has been used to test its action on man because the Merck supply became exhausted.

alcoholic distillates of the root, but this odor lasted only a few minutes. The odor was most likely due to the presence of a volatile oil, but its quantity was so small, or it was so exceedingly volatile, that it could not be isolated qualitatively or estimated quantitatively. The fixed residue remaining in the vessel in which the evaporation took place consisted of fats and wax, which were not further investigated.

One kilogramme of the root, which had been previously extracted with petroleum ether and washed with about 2 litres of the same fluid, was macerated ten days with 2 litres of ethyl ether. The ether extract was collected and evaporated spontaneously, and the remaining residue, which was very small, and consisted mostly of fat which had escaped solution by the previous treatment with petroleum ether, was treated with water containing a couple of drops of dilute sulphuric acid, filtered and allowed to evaporate. Nothing was obtained.

The above-mentioned quantity (1 kilo.) of the powdered root which had been macerated with ethyl ether was now macerated ten days with strong alcohol. The extract obtained was dark brown in color, and contained only tannic acid and coloring matters.

The same powdered root which had been macerated with strong alcohol was dried at 35° C., and macerated twenty-four hours with 3 litres distilled water. The evaporated aqueous extract contained nothing but tannic acid and coloring matter which had not been wholly extracted by the previous treatment with strong alcohol.

The wet mass of the powdered root, after the extraction with water, was macerated twenty-four hours with 2 litres distilled water containing a very small quantity of sodium hydroxide. Nothing other than tannic acid and coloring matter were found in this extract.

The same mass of powdered root which had been extracted with water containing sodium hydroxide was now washed with distilled water and macerated twenty-four hours with water containing one per cent. hydrochloric acid. Nothing but a trace of calcium oxalate was found in the evaporated extract.

A portion of the powdered root which previously had been macerated in turn with petroleum ether, ethyl ether, and strong alcohol was treated in turn with chloroform, carbon disulphide, and benzol without obtaining anything other than fat which had escaped removal by the former treatment.

An examination was now made of the dis-

tillate obtained by distilling the powdered root separately with water and with alcohol.

One kilogramme of the powdered root was distilled with water, and the distillate concentrated by several distillations until the final distillate amounted to 150 c.c. This was divided in three equal portions, and to one portion a couple of drops of dilute acetic acid were added, to the second portion a couple of drops of very dilute sodium hydroxide solution were added, and to the third portion nothing was added. The three portions were evaporated in a stream of dry air, but no organic principle could be detected in any of them.

A quantity of water was added to 4 kilogrammes of the powdered root in a large copper retort, and to the latter a long Liebig's condenser was attached. Three litres of distillate, possessing the peculiar hamamelis odor, were collected, and a portion (1 litre) placed in a stoppered cylinder, a quantity of petroleum ether was added, and the two liquids thoroughly agitated, and the mixture allowed to stand twelve hours. By means of a pipette the separated petroleum ether was removed from the cylinder and placed in a suitable vessel and allowed to evaporate under a bell jar in a current of dry carbon dioxide until the odor of petroleum ether had disappeared. There remained a slight quantity of water possessing the odor noticed in ordinary aqueous distillates of hamamelis, but in more marked degree. Upon warming gently on a water-bath the odor entirely disappeared, and upon continuing the evaporation no fixed residue was left in the vessel.

The remaining 2 litres of the above-mentioned distillate were redistilled several times in order to concentrate the volatile substance in small volume of water. The final distillate, amounting to about 400 c.c., was placed in a stoppered cylinder and agitated with petroleum ether, and allowed to stand twelve hours. The petroleum ether was removed with a pipette and evaporated in a stream of dry carbon dioxide until the odor of petroleum ether was no longer perceptible. The residue consisted of a slight quantity of water, in which was observed what appeared to be an exceedingly small globule of oil, and which disappeared in very little time. The odor was strongly hamamelis-like, and disappeared upon warming on the water-bath, as did also the remainder of the liquid in the vessel without leaving any solid matter.

Four kilogrammes of the powdered root were distilled with alcohol until 3 litres of distillate were obtained. The three litres were

twice redistilled, and the distillate obtained in the final distillation, which amounted to 300 c.c., was placed in a stoppered cylinder and agitated, and allowed to stand twelve hours. The petroleum ether was removed and allowed to evaporate in a stream of dry carbon dioxide. When the petroleum ether had completely evaporated, there remained several minute globules of oil, hardly sufficient to produce the tiniest grease-spot on a piece of paper. It possessed the hamamelis odor, which disappeared in a little time.

The results which we have reached with hamamelis are in accord with those of Dr. Hector Guy, of Paris, who came to the conclusion, as the result of numerous experiments, that hamamelis *Virginica* is not toxic; that it has no special physiological action on the vascular system; and that it contains no alkaloid. We have shown that there is a very large percentage of tannic or gallic acid in the fluid extract, and the results which have been obtained by some physicians by the use of this fluid extract in cases of hemorrhoids and varicose veins are apparently explained by the presence of the astringent principle. The tannic acid, of course, would not come over in the distillation; therefore the much-used and still more lauded witch-hazel, or the so-called distillates of witch-hazel, must depend for their virtues upon the alcohol which they contain and the faith which they inspire.

MEDICAL DEPARTMENT,  
UNIVERSITY OF PENNSYLVANIA.

### *THE ACTION OF THE BROMIDE OF NICKEL.*

BY HOBART AMORY HARE, M.D. (UNIV. OF PA.),  
PHILADELPHIA, PA.

THE bromide of nickel was first brought to the attention of the profession, I believe, by Dr. J. M. Da Costa as a remedy for epilepsy and kindred disorders. The literature concerning it is limited, and few reports on its use and value have been made. This article is designed to call attention to a remedy which from all reports appears to be of value, in order that additional clinical research may be made by those who have the opportunity to give it a fair trial.

The chief interest in this drug centres on its action on the nervous system, and while analogy points to the belief that its action resembles the other bromine salts, the writer thought it well to perform the following experiments: If 3 grains of this drug be given

hypodermically to a medium-sized frog, he rapidly becomes quiet and drowsy, more and more vehement stimuli being required each moment to make him move; pricking with a pin soon fails to call forth any response. After ten minutes have elapsed the drowsiness passes into stupor, and the batrachian allows its toes to be burnt off without moving. The question at once arises, Is this failure of response to pain due to an action of the drug on the receptive centres in the brain, spinal cord, or on the sensory nerves? Analogy, again, tells us that the drug would hardly depress the brain receptive centres without also affecting the same centres in the spinal cord, and the truth of this is demonstrated by the fact that reflex action was lost, so that even a spinal movement of the limb failed to take place. If both hind legs of a frog be partially severed from the body in such a manner that the sciatic nerve is the only bond of union between the limb and the trunk, and a hypodermic of 3 grains of the salt injected into the left leg, it will be found that from the first there is a progressive failure of function on the part of the sensory nerve-fibres, for both electrical and other stimuli fail to call forth any reflex action or other movement in the poisoned member, while much weaker currents and irritants produce marked movements, both of pain and by reflex in the right leg. It seems likely, however, that under these circumstances there is at the very first only a cutaneous loss of sensation, since stimuli of a superficial character, which caused no muscular movements through reflex or pain, when applied directly to the nerve-trunk itself brought forth a response. I reiterate that this condition was only at the very first and of short duration. This experiment was now repeated, with the exception that strychnine was given into the posterior lymph-sac at the same time the bromide was injected into the leg for the purpose of stimulating the spinal cord to such a pitch that even the faintest impulse from the periphery would be recognized.

Notwithstanding the presence of the strychnine, which brought on a spasm when the unpoisoned leg was touched, strong galvanization of the poisoned limb at first only brought out slight response, and finally failed to produce any effect at all. Again, it was found that if the sciatic nerve, just as it emerged from the pelvis, was soaked in a solution of 4 grains to the drachm of this salt, stimulation, either of the foot or of the nerve itself, at the point of exposure, caused but slight response, and if the drug remained for five

minutes in contact with the nerve, no impulse apparently reached the cord, even when strychnine was again given for the purpose already detailed. That this was not due to any extraneous cause was proved by having the nerve in the opposite leg as much exposed to the air as its poisoned fellow, and by using the same stimuli to that nerve in order to obtain control results. That the drug affects the efferent nerves as well as the afferent was also proved by like experiments in other frogs. Thus, if the drug was injected into a partially severed leg, or if it was applied for some moments to the nerve-trunk of such a leg, strychnine having been injected into the trunk, it was found that during a convulsion the poisoned leg escaped entirely, while the unpoisoned partially severed leg was tonically contracted. This experiment was so frequently performed that there can be no mistake as to the result. Along with the failure of the nerve-trunks comes later on loss of muscular contractility, for in a leg to the muscles of which was applied for some minutes the 4-grain solution already named, it was found necessary to increase the strength of the current to twice the strength required to contract the normal muscle.

On the spinal cord the drug exerts its influences very powerfully and rapidly. After the giving of 3 grains hypodermically into the trunk there was progressive failure of reflex motion, and that this was not due to the influence of the drug on the nerve trunk already described was proved by preparing a leg in the same manner as before, and by tying the artery of a leg previous to the administration of the drug, both of which procedures of course protected the nerve-trunks in those limbs. This result was verified by using strychnine and the bromide of nickel together, when it was found that larger doses of the excito-motor were needed to produce convulsions than when no bromide was used. Again, direct stimulation of the spinal cord when the drug was applied to it, failed to produce movement.

If the cut-out heart of a frog be dropped into a solution of the bromide of nickel of the strength of 4 grains to the drachm of water, its movements are instantly stopped, and do not return even when the viscus is immediately withdrawn from the fluid and dipped in pure water to rid it of the poison. Galvanization of the heart-muscle also fails to produce movement, and it is evident, therefore, that this salt must in large doses paralyze the contractile power of the heart-muscle. As a control experiment, the hearts of other frogs

were exposed as they lay in their pericardial sacs and the solution above named dropped on them. In a period of time only slightly more prolonged than when the viscus was isolated, the heart stopped in diastole. The same result is also obtained more slowly if 10 grains of the drug are administered hypodermically, the cardiac movements gradually becoming more and more irregular and imperfect, until they stop altogether. According to several manometrical tracings taken from the higher animals, as represented by the dog, it is evident that this salt affects the heart of the mammals in the same manner as that of the batrachian. If a large dose (15 grains) be injected in ten seconds into the jugular vein, the heart is instantly stopped, so that the manometer pen falls almost perpendicularly to the abscissa line. That smaller doses depress the heart also is shown by the fact that even a dose of 1 or 2 grains decreases the height of each individual pulse-wave very considerably, and produces a fall in rate and pressure. If the above-named doses are used, the rate and pressure return in the course of ten seconds to their normal points, but cardiac force, although it recovers slightly, does not ever again regain its former strength. As the size of the dose is increased the cardiac force progressively fails. Large doses depress the arterial pressure very considerably, the fall seeming to be due to cardiac failure as well as to vaso-motor palsy. Both small and large doses momentarily slow the heart, and that this slowing is not due to stimulation of the inhibitory nerve but to weakness seems probable on account of the fact already proven, that the drug is a paralyzant to the heart-muscle; and also because of the feeble pulse-waves which accompany the decrease in rate, and which in no way resemble the pulse-waves of inhibition. Apparent contradiction to this belief lies in the fact that when the heart had been slowed from 192 to 132 beats per minute by the injection of 10 grains of the drug, section of the vagi caused the rate to rise to 186 per minute, with an accompanying rise of pressure due to the increased rate. While at first sight this seems to prove the falsity of the opinion already expressed, I do not believe that it is in reality proof of vagal stimulation for several reasons. In the first place, the increase of rate on section of the vagi did not reach the rate present previous to the dose (*viz.*, 192 per minute), which it should have done had the slowing been due to vagal stimulation. Indeed, under such circumstances, the rate

should exceed by many beats the normal, because before the dose and section the inhibition always present was exerting its effects, while after section of the vagi *all* inhibition was swept away.

The second reason for clinging to the first opinion has already been stated, consisting in the weakness and feebleness of the heart, with the knowledge that in large doses the drug acts as an absolute paralyzant of the heart-muscle. It is very evident also that the drug produces vaso-motor palsy eventually if in large enough dose, from the progressive lowering of arterial pressure from the moment the first dose was given until the last.

Details of experiments showing rise of rate and pressure after section of vagi.

I. Dog; weight, 17 pounds. Bromide of nickel. Arterial pressure already depressed by previous doses.

The only clinical report on this drug which I have been able to find is that of Dr. R. Leaman, in the *Medical News* for April 18, 1885, who, after getting unsatisfactory results from its use at first, concludes that the remedy is of great value. The bromide of nickel is a greenish-yellow powder, of a sharp, almost burning taste; when dissolved in water the solution becomes almost grass-green. Notwithstanding its burning taste, the writer quoted says that he has found it borne by the stomach better than all the other bromides, and he also recommends its use in an effervescing form, made by mixing the salt with bicarbonate of sodium and tartaric acid, moistening with alcohol, passing the moist powder through a sieve, and then drying it in a warm closet. He then goes on to say that he estimates that 10 grains of the nickel salt is equal in efficiency, in his opinion, to 30 grains of the bromide of potassium. He believes it to be particularly indicated in those cases suffering from melancholia and hysterical conditions, and quotes cases of sexual melancholia and epilepsy which were much benefited by the use of the drug. The dose he believes to be from 5 to 10 grains, but states that when the effervescing mixture already named is used slightly larger doses are necessary.

*A FEW REMARKS UPON THE METHODS  
EMPLOYED NOWADAYS FOR THE DIS-  
POSAL OF THE DEAD, WITH SUG-  
GESTIONS TENDING TO REM-  
EDY THE PRINCIPAL EVILS  
OCCURRING AS A RE-  
SULT OF THESE  
METHODS.*

BY A. F. EKLUND, M.D., STOCKHOLM, SWEDEN.

**H**APPILY, the dangers to which individuals and the public at large are exposed as regards health, occurring as a direct result of the presence of cemeteries, are so limited, and imbued with so little authenticity, that the necessity of speaking upon a question already solved to the satisfaction of almost all interested parties may be relegated to a position of doubt. But, however, as the author of these lines belongs to the minority, certainly

not small, of those who have gradually arrived at a positive opinion that not only the arrangement of cemeteries, but also that certain funeral practices offer grave and unwarranted imperfections, he has not hesitated to formulate objections,—first, as to the manipulation of corpses during the time which elapses between the moment of death and the final burial; second, as to the rules and regulations promulgated by competent authorities upon these subjects; and, third, upon projects proposed by honorable colleagues tending to decrease the imminent dangers to general health occurring as a consequence of the putrefaction of the interred bodies.

In the first place, allow me to call your attention in a few words to a few details representing, in my opinion, the most natural explanation of the fear, nay, the detestation, in which cemeteries are at present held by the public. The execrable hygienic conditions of the greater portion of our fellow-men who form the lowest classes of society cause many organisms to fall into a state of degeneration long before the last spark of life has left the body. As an example, I need only cite the case of little children affected with intestinal catarrh or with diphtheria, who, since their birth, have breathed night and day the emanations of excrementitious gases, alcoholic exhalations, and tobacco-smoke of adults living in the same hovel. The cadaveric odor of such corpses is far beyond expression, and natural instinct suffices to demonstrate the fact that such cadavers are prodigiously venomous and pestiferous. Corruption and its resulting fetid emanations reach their greatest intensity, however, when, in addition to the wretched hygienic conditions, the different forms of debauch associated with prolonged sleeplessness and unwarranted loss of rest have contributed to undermine the health and accelerate disorganization. To what excesses have drunkards, syphilitics, and tobaccophiles not “putrefied” themselves long before death! What rapid progress the process of putrefaction must make immediately after death! What disgusting cadavers!

Again, I want to cite two of the most frequently met with diseases,—phthisis and carcinoma. What nauseating infection do consumptives and the cancerous disseminate, as a rule, around them, especially when the end is near at hand! What progress the putrefaction process must have already made during their miserable life! As is well known, there frequently results in these affections, and almost always in nephritis, in fatty accumula-

tions, in heart-troubles, and adipose degeneration of the latter, in cirrhosis of the liver, etc., a dropsical state, presenting itself early or late in the course of these affections. When, after all medicinal means have failed, and the patience of the physician and the surroundings has given way, recourse is had to scarification of the skin, so as to allow the serum to run off, if it has not already begun to do so spontaneously. It is evident that after death the flow of serum continues, nay, often increases. The bed and bedding, and frequently several boards of the floor, have imbibed a quantity of the fluid, which not only contains different patho- and sapriogenic germs, but constitutes a potent fertilizer for the micro-organisms which find themselves beforehand in the dust between the cracks of the floor.

What of autopsies? Are hygienic considerations conscientiously observed, or does want of all cleanliness not demonstrate the contrary? Sometimes, in carrying the dead out of the house in which the demise occurred, it happens that the cadaveric humors ooze out through the slits of ill-constructed coffins, soiling the balusters, the halls and stairs, the church floor, etc., and it frequently happens that indifference is pushed to a degree sufficient to allow the places and things soiled by the cadaveric fluid to remain uncleansed. Generally, however, the cleansing process is at once begun, but it in no way differs from the usual every-day procedures, their efficiency depending entirely upon the habits and natural tendencies of the persons intrusted with the job. It stands to reason that the infiltration of cadaveric fluids into the dirt lying between the floor-boards, etc., must form a source of great danger, in a sanitary point of view.

Another state of things may be added to the above, one which repeats itself every day. It is certainly sad that no student of sanitary science has as yet given it serious attention, although it is well worthy of it, the more so since no voice has as yet been raised against it with an energetic appeal for reform. I am alluding to the careless changing of residence, or of furniture, and to the reckless wearing of clothes, etc., having belonged to deceased individuals, and left by them as legacy, etc. How many chances do parents take for their children when, unsuspectingly and without due circumspection, they place their pets in rooms which have probably contained within the last six months the corpse of a case of diphtheria, scarlatina, smallpox, etc. ! Again,

what risk does an individual not run who occupies the non-disinfected rooms or clothes of a recently deceased tuberculous or carcinomatous patient? How many times have we observed large white swellings over the kneecaps of small children, the result of a splinter introduced under the skin while crawling? This demonstrates that hygiene has as yet not only many problems of the highest importance to solve theoretically, but that police ordinances should cause the hygienic mandates to be practically enforced.

An important indication of the general appreciation of these dangers is, that the partisans of cremation are increasing in number every day, and it is quite likely that the time is not far distant when its practice will be recognized by law. While I do not myself belong to the advocates of incineration, I do not hesitate to admit my acquiescence to this mode of procedure, on the condition that the applicants present a death certificate, signed by three persons, belonging, if possible, to different "beliefs," for instance, an idealist, a realist, and an atheist, each having cared for the patient upon his death-bed. I am positive that this return to pagan customs, which cremation certainly is, will not by any means involve the extinction of Christianity, as desired probably by many proselytes of incineration, and I seriously believe that one can be a passable Christian and believe in this method of treating the dead, which does not possess the least anti-Christian tendency; but, however, I perhaps do not err greatly in supposing that in the future, as now, burial in sacred tombs, such as that of our Saviour, for instance, will constitute the general rule.

In the first place, we must determine what reforms, in the methods of burial now employed, are of prime necessity. I have already alluded to the disgusting state of dissolution into which a large number of sick subjects have arrived before death. In cases in which this preliminary disorganization does not exist, only a very brief period transpires, even in our cold climates, before signs of putrefaction present themselves, the disorganization then progressing rapidly. At all times and in all countries great repugnance, horror, and aversion have existed at the sight of putrefaction. It is, in fact, terrible for loving parents to witness the putrid degeneration of one or more beloved children, or of relatives and sincere friends to behold those they dearly loved undergoing the same fatality! How terrible! This forms one of the principal causes for the daily increasing sympathy in

favor of embalming, which already has assumed sufficient importance to form a majority, which places the cremation clique in the shade. For this I would humbly solicit that an interest in the public mind be awakened in favor of embalming, and that its benefits be extended to and obtainable by everybody, even those deprived of all resources. In fact, I maintain that embalming of the dead should become obligatory with time, provided that a general agreement as to methods of procedure and ends to be attained be reached. Old women's unconfirmed and unverified tales about the burial of living subjects will at the same time be brought to an end.

It is a well-known fact that the process of putrefaction, of which vibrios, bacilli, and micrococci are the foundation, and which are found in quantities innumerable in the intestines of human organisms during life, progresses rapidly during the first, or the first three, months after death, when the simultaneous colliquative softening of the organs causes the bacteria of putrefaction to develop in myriads. The quantity of putrefactive products, liquid and gaseous, formed, which penetrates the ground, and especially the underlying stratum, is much more considerable during that time than later, when the decomposition of the cadaver decreases after the liquids have escaped and the bacteria of putrefaction have been supplanted by mere moulding of the remnants. The putrefactive process is most rapid in the cadavers of the victims of epidemics, without demonstrating in any manner that specific pathogenic schizomycetes, for instance, those of scarlatina, or those of ileo-typhus, are rendered inactive, or destroyed by the bacteria of putrefaction.

Thus have things been conducted to the present day. In my opinion, however, the best means would be to encourage rapid destruction of cadavers by chemical means, reducing at the same time the process of putrefaction, and consequently checking the deleterious influence upon the ground, the water permeating it, and the surrounding atmosphere.

The simplest procedure that I would suggest, for the purpose of arresting putrefaction, would be to inject a saturated solution of common salt, with a little "depurated ferric acid" and boracic acid, into the arteries of cadavers. In cases of death from infectious diseases, however, it would be advisable to inject first a solution of biniodide of mer-

cury or of bichloride of mercury, dissolved in a hot solution of iodide of potassium, this again in alcohol, or a solution of chloride of ammonium or sodium. As is well known in the medical world, mercuric iodide heads the list of disinfectants. According to Miguel, 25 milligr. of biniodide of mercury and 30 milligr. of bichloride of mercury are sufficient to prevent the putrid degeneration of a quart of beef-tea. To obtain the same result, 165 gram. of chloride of sodium must be employed, so that the action of common salt is inferior to that of biniodide of mercury 6600 times. Again, since other minerals, such as sulphuric, nitric, or hydrochloric acids possess powerful energy in preventing the multiplication of schizomycetes, and are sold at very low price, it would be advantageous, and at the same time cost almost nothing, to introduce, by means of a sound through the œsophagus, the trachea, and the rectum, a certain quantity of these acids into the stomach, lungs, and colon. Again, I would recommend that the trunk and the extremities of the cadavers be wrapped with a layer, 5 to 8 millim. thick, of lime packed into long flat bags that can be wrapped like a belt around those parts.

It would be desirable that police ordinances relating to the burial of the dead contain provisions with a view to enforcing the following features: That the bottoms of coffins be made impermeable to water, and be covered with a layer, 5 to 8 mm. thick, of substances possessing absorbent properties, such as dry earth, the crushed acicular leaves of resinous trees, ashes, saw-dust, and charcoal-dust. Just before closing the coffin, the hands and face should be covered with lime.

For the fulfilment of the above measures a new form of educated labor would become necessary,—there must be "embalmers," of both sexes; while to insure the proper carrying out of the project, a special police service, under an inspector, should also be established. The former would be specially instructed in the performance of their duties, and only to exercise them when thoroughly acquainted with the several manipulations. At the occurrence of a death, the police inspector, notified at once by the friends of the deceased, would repair to the house of the latter, accompanied by the embalmer, who should at once carry out his duties, and thus check from the start any danger of infection.

*THE HYGIENE OF OLD AGE.*

By H. C. WOOD, M.D.

WITHIN a few weeks the city of Philadelphia has been called upon to mourn the loss of the man who, although very far from intellectually the greatest within her borders, as a citizen was pre-eminently chief. Dying at the age of eighty or eighty-one years, he is universally spoken of as being gathered like a ripened sheaf; yet, within a week of his burial, he was full of mental and physical vigor, and his death at the time was as unnecessary and avoidable as though he had only reached threescore years. A very notable percentage of the deaths of persons who have been successful in life, and have attained beyond the seventieth year, could be, by proper care, long postponed. Failure in life in a large proportion of cases saps vitality, and the man who carries the load of self-knowledge of such failure lives under a persistent strain, whose effects, though usually not recognized, are none the less irresistible. In order to protract an advanced life it is well to understand not only the dangers that beset such life, but the reason why old age has been attained.

The humorist is greatest when underlying his rollicking is the lesson of a great truth; but perhaps few readers, when they enjoyed the broad fun of the "One-Horse Shay," as portrayed by our inimitable Holmes, have recognized the fact that the man who reaches old age does so largely because he has been constructed upon the principles of the famous vehicle "that ran for a hundred years and a day." Barring accidental deaths from railroad collisions, typhoid fevers, lightning-strokes, and other more or less preventable causes, the man who is so built that he is equally strong in all his parts, lives out his appointed days.

Excessive strength in one part is a veritable source of danger. The athlete perishes because his over-developed muscular system perpetually strains and finally wears out a heart or a lung that was originally constructed for a muscular apparatus of half the power of that which he has artificially built up. The larger proportion of mankind die early on account of some local weakness. It ought to be generally recognized that human age is not to be counted by years, and that in some constitutions the general tissues are older at fifty than they are in other individuals at one hundred. Many of the cases of so-called neurasthenia, or nervous exhaustion, of men and

women suddenly or gradually breaking down at forty or fifty, ostensibly from overwork, are really cases of premature old age, and are to be nursed and treated precisely as other individuals would be who had reached to four-score years. Moreover, a larger proportion of early deaths are the result of some vital organ being originally endowed with a longevity less than that of the rest of the organism. The reason that consumption is so often utterly irremediable is to be found in the fact that in not a few cases the lung has reached its allotted term of days, and must die because its vitality is exhausted. If an eye, or other not vital part, fails from lack of vital power, the man exists; but if a lung dies, he perishes.

The result of these lucubrations is to lead us to this point, namely, that the individual who enjoys fair health at seventy-five years of age has probably been built upon the principle of the "One-Horse Shay," and that he should be treated as a wise man would treat such a venerable instrument of progression. He would certainly keep it off Philadelphia cobble-stones, and allow it only to be bowled along some smooth turnpike, and especially would he avoid all jolts and jars which would throw an unexpected strain upon one part. The principle involved in such case is that which is most vital in the treatment of the old,—protection, and especially protection from strain of any one vital part. An old man exposes himself to inclement weather, and especially to a high wind, which suddenly drives the blood from the surface upon the internal organs, and at the same time by its very force checks the enfeebled movements of respiration, which aid in forcing the blood out from those organs. As a result, the man perishes at once, because he has thrown too great a strain upon a weak heart, or, if able to momentarily resist the strain, dies in a few days of pneumonia, due to the congestion of the lung. I have known the sudden shock of good news to strike the old man down, as fatally as the pole-axe fells the bullock, by causing the blood to rush with renewed force through the brain, and tear its way through the weakened walls of the blood-vessels. Again, the violent emotion of a sudden bad news may overwhelm a heart which, with care, would have sufficed for its duties for many years. The young athlete in the boat-race pulls at his oar until he drops from heart-strain, and, if the heart-strain has not been too severe, recovers himself in a few weeks, because the vital elasticity of the heart-tissues is in high-

est vigor. But the enfeebled and brittle heart-muscle of the old man, strained in some hurried effort to catch a railroad train, or in some equally unreasonable procedure, has no power of recovery, and rests itself only in death. What is true in regard to the healthy ordinary conditions of the old man is more abundantly true in regard to the diseases of the old. Medicines that perturbate—measures that bring relief through violent local actions cannot be borne, and are not to be employed. At the same time, when possible, it is most essential to arrest at once any incipient disorder in the aged. I knew an old doctor, renowned in all lands, who lived ten years beyond the period attained before by any one of his name, largely because, knowing himself thoroughly, every few weeks he arrested in its inception an attack, which, in a few hours, might have gathered fatal force.

I feel some hesitation in attempting to point out in detail the application of the principles which have just been enunciated, lest this paper may fall into the hands of aged persons, and be substituted for a careful consideration of their individual cases by some skilful medical practitioner. Every person, when he advances in years, should go over his whole methods of life and personal habits with some wise counsellor, and should adapt his mode of life to the peculiarities of his individual case. With this warning, it is probably safe to briefly point out some of the more important details in the regulation of the life of old people. The first question is in regard to food. The teeth in old age are, of course, lost, and they should, unless under exceptional circumstances, be replaced by artificial teeth, for the thorough chewing of food is even more necessary in the old than in the young, because in the old the digestive powers are apt to fail. With the best artificial teeth mastication is apt to be imperfectly performed; hence the food of the aged should be soft and readily comminuted, and especially should it be of easy digestion. Very few old people need stimulating diet; very many are injured by an excess of nitrogenous food. The kidneys, like all other organs, are feeble, and, if meats and other rich foods are used in excess, they greatly increase the strain upon these organs. Milk and milk products, or preparations of breadstuffs cooked with milk, should form a very large proportion of the food of the ordinary aged individual; but individual peculiarities differ so much that personal medical counsel should in all cases be taken, so that the diet may be regulated to the needs

of the individual case. Very many old people are hurt by the use of food in excessive quantity; but little exercise can be taken, all growth has ceased, and the bodily furnaces which make heat are able to destroy by very little of food fuel. Some little time since I had occasion to lecture on this subject at the Philadelphia Hospital, and an assertion that I then made that most old people are more comfortable, enjoy better health, and probably live longer for the use of wine, has met with very severe disapprobation at the hands of some of the profession, whose strong sympathy with the temperance movement dominates their judgment. No valid reasons have, however, so far as my judgment goes, been brought forward to lead me to change my opinion. In the overfed American people the habitual use of wine during youthful or middle age and vigorous health is, we think, an injury rather than a good; but when the powers of life are failing, when digestion is weak, and the multitudinous small ills of feebleness perplex and annoy, one or two glasses of generous wine at dinner aid digestion, quiet for the time being much nervous irritation, and in no way do harm. The sum total of ruin wrought by alcohol in the world is appalling, but it is not lessened by our shutting our eyes to the good that wine properly used may achieve. When in the aged there is a distinct failure of vital power, and especially of digestive power, the call for the habitual use of alcoholic liquors is, in my opinion, imperative. The danger of the formation of any evil habits when a man has crossed the line of seventy is so slight, that the most conscientious physician need not hesitate in recommending the daily use of alcoholic beverages to his patient.

It is, perhaps, not universally recognized, that in numerous cases of various character death finally is due, in greater or less measure, to cold and to an absolute failure on the part of the body to keep itself warm. In the old the heat-making functions are exceedingly low, and hence it is that few old people are comfortable in a room whose temperature is less than 80°. It is especially important, therefore, that an abundance of clothes be worn by old people; but the very weight of the clothes oppresses, so that it is important that lightness of material should be combined with warmth. There is no ordinary garment which compares in heat-preserving powers with the buckskin jacket, and, in our climate, every man who passes the seventieth year should furnish himself with such covering. At first the jacket should be only worn when

going out of doors ; but in very advanced age it should form a part of the habitual underwear. The jacket should be high up in the neck and long in the sleeves, and should be of such a length as to thoroughly cover the abdomen. If worn as an under-jacket, it should be perforated so as to allow the escape of the vaporous emanations from the body. Whenever there is any tendency to abdominal weakness, in addition to the jacket and the ordinary warm underclothes, an abdominal flannel bandage should be worn. It ought not to be forgotten that the mass of blood of the human body is in the abdominal organs, and that this is especially so when the circulation is sluggish. It is affirmed by authority, that after death all the blood of the body can be put in the relaxed abdominal vessels ; hence the importance of maintaining the abdominal warmth, and hence also the good effect in feeble people with pendulous bellies of the bandage, which helps to sustain the relaxed vessels, and thereby maintain the general circulation. The mechanical effects of tight abdominal bandages are well understood by the profession in the treatment of ascites. It is well known that the sudden removal of the fluid by tapping over the abdominal cavity take away so much pressure from the abdominal vessels as to cause them to relax, and draw the blood away from the heart and lungs and brain in sufficient quantity to produce fainting. It is to prevent this that the patient about to be tapped is bound up, and the bandage continually tightened as the water flows off. The importance of the habitual abdominal bandage is, perhaps, no less although not as universally recognized.

*ON THE USE OF QUININE IN CHRONIC DYSENTERY.*

By C. J. MARSH, M.D., THRACE, ARK.

THE report by Dr. Bevill in the last number of the *GAZETTE* of a case of chronic dysentery cured, as he claims, by quinine, leads me to report a case that came under my care a few years ago.

In the spring of 1880, a man, about 35 years of age, applied to me for treatment of a chronic dysentery of four years' standing. He gave the following history of his case :

Four years previous to his coming under my care he had been attacked, while working on a Mississippi River steamer, with acute dysentery of a violent type, for which he had,

I presume, the ordinary treatment, and made a partial recovery. He had, however, never at any time been entirely well, as the stools all the time were of a more or less dysenteric character.

When he came to me he was much emaciated, and suffered a great deal of pain both day and night, as the bowels moved from twelve to twenty times during the twenty-four hours, the discharges being of the typical dysenteric character.

On the supposition that there was more or less of a malarial element in the case, I gave him 5 grains of quinine three times a day in capsules.

In connection with the quinine, to relieve pain and tenesmus, and to secure rest to the bowel, and to facilitate the healing of the ulcers of the mucous membrane, I gave him a pill three times a day before meals, composed of subnitrate of bismuth 5 grains, nitrate of silver and morphine each  $\frac{1}{8}$  grain, with enough extract of gentian to make a mass. I gave him also an occasional laxative dose of castor oil at night. By following out this course of treatment, with proper regulation of diet, he made a perfect recovery in three months.

While it would be absurd to claim that the quinine effected the cure in this case, it seemed to do its full share in bringing about that happy result,—that is, I consider quinine as a valuable adjuvant in the treatment of such cases when caused or complicated by malarial intoxication.

*POISONING FROM BELLADONNA OINTMENT.*

By DR. J. BLOOMFIELD, NAPOLEON, OHIO.

THE following case is of interest, as showing the extreme susceptibility of some persons to the effects of belladonna.

L. D., a strong, healthy girl, 12 years of age, was recently taken with pneumonia. About the time of the crisis I noticed the parotid gland began swelling, and by the second day after the crisis the gland was considerably swollen and painful. At this time the pulse and temperature were normal, and resolution well established.

I directed that belladonna ointment (U. S. P.) be rubbed on the skin over the gland night and morning to relieve the pain. The ointment was applied in the evening (the child sleeping during the night) and again in the morning.

About two hours after the last application I was called in a hurry to see the patient.

I found her pupils largely dilated, face very red, and imagining she saw all kinds of horrible things around her. Her hallucinations were of such a character that considerable force was necessary at times to keep her in bed. Pulse 76, temperature 98° F.

This condition continued till nine o'clock in the evening, when the patient went into a quiet sleep, not awaking till morning.

I visited her the next morning, and found hallucinations had disappeared, the pupils but little dilated, and only slight redness of the cheeks remaining.

The swelling of the gland subsided in a few days, and the patient made a good recovery.

#### MYCOTIC ENDOCARDITIS.

DR. WYSSKOWITSCH details the particulars of an experimental inquiry into the nature of ulcerative endocarditis (*Virchow's Archiv*, 103, Heft 2), to which is prefixed an account of the histological examination of twelve cases of endocarditis in the human subject. Four of these cases were chronic valvular thickening with calcification and necrotic areas, surmounted by warty deposits of fibrin; in four others the vegetations were more or less vascularized at their union with proliferated endothelial layers (thrombo-endocarditis); the ninth case appeared to be a chronic condition of the preceding; the tenth and eleventh showed post-mortem œdema after chronic endocarditis, with, in one case, bacteria (undoubtedly saprophytes). Lastly, there was a recent case of ulcerative endocarditis, which yielded abundance of micrococci on the valves, in the spleen, and kidneys; on cultivation the micro-organisms had the characters of staphylococcus pyogenes aureus. The experiments which form the second part of his paper consisted in inflicting on rabbits an injury of the aortic valve by means of an instrument passed down the carotid artery; then injecting into a vein a few hours later cultures of various micro-organisms. It was shown that the operation of piercing the valve was well borne, and not *per se* followed by any pathological consequences; but that the inoculation was often productive of a malignant mycotic endocarditis upon the injured valve, with secondary metastasis, as in human ulcerative endocarditis. These positive results occurred when the inoculation was made with either of the following micro-organisms:

Streptococcus pyogenes, staphylococcus pyogenes aureus, and coccus sepsis (Nicolai); but the injection of micrococcus tetragonus and bacillus pneumoniae had no such sequel. It was also found that the staphylococcus produced much inflammatory reaction and supuration, whereas the streptococcus, although causing much more valvular deposit and more numerous infarctions, had no such severe action. The changes in the heart and vessels were not limited to the valves pierced by the stylet; the micrococci growing also on the mitral valve and aortic wall, which happened to be eroded by the passage of the instrument. It is, therefore, suggested that mycotic endocarditis may be of various forms depending upon different varieties of micro-organisms. Other experiments to induce endocarditis after inhalation and subcutaneous injection of streptococci yielded negative results; but it was found that the rabbit can only bear inhalation of very small quantities, and it was doubtful if the micro-organism entered the blood-stream at all. Professor Orth, under whose direction this research was undertaken at Göttingen, comments in another article upon the results obtained; they prove, he thinks, that the term "disposition" is no empty one, the mechanical injury of the tissue laying it open to the attacks of the micrococcus which is deposited in the clots. The experiments show also how slight may be the amount of injury required to so lower the vital resistance of the tissue.—*Lancet*, April 10, 1886.

#### ANTIPYRIN IN PERNICIOUS FORMS OF MALARIAL FEVER.

DR. JOHN HOPE POTTER, writing to the *Lancet* for April 10, 1886, states that he has obtained very satisfactory results in the treatment of severe forms of malarial fever by the administration of large and repeated doses of antipyrin; he says that particularly in cases of a remittent type, which are not amenable to ordinary treatment, whether by quinine, arsenic, or diaphoretics with aconite, the administration of antipyrin has produced an instant cure in cases which for weeks had been quite unaffected by the ordinary remedies. In a few cases where the effects were found to be unsatisfactory, abscess of the liver, phthisis, or other complication subsequently developed. He is of the opinion that in pernicious forms of uncomplicated malarial fever we have in antipyrin a most valuable aid to treatment.

### ADMINISTRATION OF THE SALICYLATES.

CLINICAL experience seems to us to have proven that the salicylates are almost as much of a specific in rheumatism as is quinine in intermittent fever. The cases are further parallel in the facts that precisely as we have no knowledge of the nature of the malarial poison, and the way in which it affects the system, so have we no knowledge of the nature of the rheumatic poison and its relation to the system; if, indeed, rheumatism be due to the presence of the poison, and be not after all a neurosis. Further, since the pathologist has failed to give the basis, the therapist cannot explain either how quinine acts in malaria, or how the salicylates act in rheumatism. Until our pathological knowledge be more complete, to essay an explanation of the therapeutic facts would be to attempt to build a house in the air without a foundation.

The best method of administering quinine in malarial fever is even yet one concerning which physicians are not agreed, but in our opinion the right method is not to give for a length of time 6, 8, or 10 grains a day of the

cinchona alkaloid, but to employ it in overwhelming dose, so as to at once abort the intermittent paroxysm. We are much inclined to believe that the proper use of the salicylates is in the same way, and that many of the failures that occur with it in rheumatism are due to an incorrect method of administration. We have always obtained the best results by giving the remedy for thirty-six hours in doses as large as can be borne, then ceasing medication for one, two, or three days, and again giving a very large dose. Even the Apostle Paul expressed fears lest he himself should at some time forget his own teachings, and most of us occasionally lose sight of our own principles. Such forgetfulness led quite recently to a new lesson concerning the salicylates. A patient had been under our care for six weeks with sciatica, the salicylates of sodium had been exhibited in moderately full doses daily for weeks with only a measure of improvement, then the case was treated with iodide, etc. Finally, the symptoms not yielding, the man was put back upon the salicylate, and was ordered a dessertspoonful of a mixture three times a day containing 30 grains of sodium salts. By mistake of the nurse a tablespoonful was given instead of a dessertspoonful, so that the patient got in the twenty-four hours 3 drachms of the salicylate; the consequence was an immediate arrest of all the symptoms. Those of our readers who have ever camped out in the woods will appreciate the fact that you may tap all day at a half-rotten dry log with an axe without splitting it, but one-tenth of the force thus wasted will disrupt the wood when concentrated into a single tremendous blow.

There is little or no danger from the use even of very large doses of the salicylate, provided that these doses be separated from one another so that no accumulation of the salt can occur in the system. Recent experiments show that, except in enormous amounts, the salicylates are not depressant to the circulation. Indeed, Hugues Oltremare, of Paris, and Danewsky, of Moscow, are in accord in showing that moderate doses in the lower animals produce an increase of the arterial pressure, which, according to the experiments of Danewsky, are chiefly the result of the excitation of the vaso-motor centre, as is shown by the fact that it is prevented by section of the spinal cord,—i.e., by vaso-motor paralysis. Further, in 1884, Maragliano published a long series of sphygmographic and sphygmometrical studies upon men, which showed that the arterial pressure is usually elevated,

and never depressed even by the largest therapeutic doses of the drug. It is possible that the general feeling of weakness and nervous depression which the drug in full doses undoubtedly causes has been mistaken by clinicians for the more serious cardiac depression. Only in cases of distinctly weak heart is there any reason for fear of using the salicylates in very large doses, provided, as we said before, that care is exercised to prevent any possible accumulation in the system.

There is one very important contraindication to the use of salicylates which we have not seen much dwelt upon by writers, namely, chronic congestion or catarrh of the middle ear. The tinnitus aurium which salicylic acid produces has been proven to be the result of an intense irritative congestion of the middle and internal ear. A notable deafness is always present in persons who are fully under its action, and when the inner portions of the aural apparatus are diseased this deafness is greatly exaggerated. More important than the mere temporary inconvenience and distress which is produced in these cases is the liability of permanently intensifying the existing deafness. The circumstances must be very urgent which would warrant the exhibition of full doses of the salicylates to the victims of chronic aural lesions.

#### DIRECT ELECTRIZATION OF THE HEART.

THE conditions in which heart failure is a source of danger are so frequent, that any points bearing on the treatment must possess the greatest interest, especially since the fact that heart failure implies as a rule the impossibility or the difficulty of the introduction of drugs into the circulation, therefore their action on the nervous centres, and hence necessitates the direct action of our remedial agents on the heart itself; and here we are reduced either to the problematic action of external stimulants or the direct action of electricity on the heart. Thorough clinical studies of the action of electricity upon the heart are at present a desideratum: the evidence at hand is not sufficient to warrant any positive conclusion, but certainly is enough to stimulate further research, and it lies within the horizon of the possible that in the future direct electrical stimulation of the heart may be a recognized procedure in all cases of severe sudden heart failure such as occur in an anæsthesia. The direction of investigation at present should be toward the determination of the best methods of applying

the electricity to the heart and of the best currents to be employed.

Owing to the inaccessible location of the heart within the thorax, it is evident that the direct concentration of the current upon the heart is opposed by very considerable difficulties. This difficulty has been to a certain extent removed by a method suggested by Dr. J. Leonard Corning (*Virginia Medical Monthly*, April, 1886), of directly applying the electrical current through the heart. The means which he employs is as follows: He first sprays or brushes the pharynx with one-eighth per cent. solution of the hydrochlorate of cocaine. When he has satisfied himself by repeated trials that the reflex nausea is abolished sufficiently to admit the introduction of the handle of a spoon as far as the epiglottis, he first introduces an œsophageal electrode well insulated, except about one and one-half inches at the point, passing it down the œsophagus until the non-insulated extremity of the instrument lies behind the heart. This region lies between the seventh and ninth dorsal vertebræ, and the exact distance through which the electrode must be passed may be determined by measuring accurately from the eighth dorsal vertebra to the mouth. This electrode is then connected with one pole of the battery, while the other is connected with a flat electrode, which is placed over that portion of the anterior aspect of the heart not overlapped by lung (a triangle, whose apex is at the fourth left sternal articulation, extending downwards and outwards to the union of the fifth rib with its cartilage, and inwards and downwards to the sixth rib).

It is evident that this method will be much more successful in localizing the electric current on the heart than passing it directly through the body. Dr. Corning says that either the galvanic current or the faradic current may be used. It is evident, however, that there must be the greatest difference in the results of these two currents. For it was found by Ziemssen in his experiments on the direct electrization of the heart, in a woman in which that organ was entirely exposed, that the induced current was incapable of producing any modification of the heart rhythm when the strongest currents were passed through the auriculo-ventricular ganglia, the body of the ventricle or the apex. It would seem, therefore, that the faradic current can never be indicated in cases where electricity is desired as a heart stimulus. On the other hand, Ziemssen found that the constant cur-

rent was able to control with the greatest exactness not only the energy and form of contraction, but also the rhythm and frequency of cardiac pulsation. With sufficiently strong currents each irritation with a constant current is followed by a complete and perfect systole of both ventricles. It is thus seen that any desired frequency above the normal rate may be produced by using a corresponding rate of interruption, each ventricular systole, as determined by Ziemssen, even when produced as rapidly as one hundred and forty per minute, being strong enough to cause a perfect and strong pulse at the same rate of the radial artery. Again, Ziemssen found that a strong constant current passed without interruption through two points on the surface of the ventricle, one being on the left ventricle, two centimetres below the left auriculo-ventricular furrow behind the vertical branch of the coronary artery, the other on the right ventricle in the neighborhood of the phrenic nerve, the rate of pulsation is doubled or trebled, to return again to the normal rates as soon as the current is broken. From these results the hope is held out that by passing the interrupted galvanic current through the ventricles, according to the method of Dr. Corning, a heart which is nearly arrested in opium- or chloroform-poisoning, in suffocation, or in various other pathological conditions, might be restored to activity; and it should be remembered here that there is no advantage in using a strong current, for increasing the strength of the current does not increase the strength of the contraction, and a current which is strong enough just to influence the beat of the heart will be quite as efficacious as an extremely strong current, and will be less liable to produce other disturbances. Of course, the possibility must not be forgotten that the phrenic nerve will probably be included in the action of the current, but this will probably not produce any untoward effect.

Dr. Corning states that he has not yet had an opportunity of employing his method in poisoning or suffocation, but that he has been greatly impressed with the benefit derived from this treatment in cardiac weakness and tremor due to excesses and any conditions characterized by intermittent and irregular action of the heart. In such cases he has obtained the most advantage from the employment of the induced current, while, on the other hand, he states that angina pectoris is undoubtedly benefited by a constant galvanic current.

#### ON *HYDRASTIS CANADENSIS*.

IT is gratifying to note the gradual disappearance of the prejudice hitherto entertained in Europe against many new American remedies. True, there is a justification for such a reserve in face of a drug coming from a strange country with no other credentials than a loud praise from its manufacturing pharmacist. But it is different with a remedy which can boast of an exhaustively tested remedial value and a fair clinical record, as in the case of *hydrastis canadensis*. Some three to four years ago this remedy was in Germany utterly unknown, except with the journalistic and didactic element of the profession. At present we find the drug known, employed, and constantly rising in the estimation of our colleagues abroad. This assertion is based upon personal observations in Germany in 1883 and 1886.

Schatz deserved the credit of having first pleaded for the admission of the American medicament into gynecological practice, while Fellner, of the famous Franzensbad Springs, first subjected the drug to a rigid physiological examination in the laboratory of Prof. v. Basch in Vienna. It appears that this crucial test turned out entirely in favor of the drug, and, with this official but indispensable sanction, *hydrastis canadensis* will be regarded and received as an acquisition by our German *confrères*.

As could be expected, the fluid extract was the principal preparation tested. The results and conclusions of Fellner's researches have been published and abstracted in every German journal of note. The *Wiener Medizinische Blätter* of February 25, 1886 (No. 8) devotes an especial article to the subject. Let us now review the outcome of Fellner's experimental investigations.

The physiological action of the drug was found to vary according to the method of its exhibition, viz., injection into the external jugular vein, hypodermic application, and administration *per os*. Fellner formulates his principal conclusions as follows:

1. Large doses (90 to 135 grains) produce a great lowering of the blood-pressure and slowing of the pulse, followed by a rise of the pressure and quickening of the pulse, and an ultimate fall of pressure, with irregularity of the cardiac action and the pulse (bigeminus, trigeminus), arrhythmia, cardiac failure, and death.

2. Medium doses (15 to 45 grains) cause similar phenomena; the blood-pressure rises,

however, higher in the first stage and falls less deeply at the end of the second stage; the terminal symptoms, such as arrhythmia, etc., are wanting.

3. Small doses (1 to 5 subdivisions of a Pravaz syringe) increase the general blood-pressure.

4. Subcutaneous injection, enema, and application *per os*, even in large doses, act similarly to small doses injected directly into the veins.

From experiments instituted after section of the splanchnic nerves or of the cervical portion of the spinal cord, after compression of the abdominal aorta, and after section of the depressor nerve, and from experiments made under suspension of respiration simultaneously with strychnine injections, it became evident that hydrastis developed its principal effects in the vaso-motor nerve-centres, thus causing vascular contraction or dilatation. The pneumogastric nerves are also influenced by the drug, as was shown after their section by the absence of the slowing of the pulse, otherwise observable in the first stage.

Finally, the drug influences also the heart directly, or the nerve-centres situated in it, as seen by the mentioned cardiac arrhythmia.

Summing up the physiological effects of hydrastis, we must conclude that the drug is not only a vaso-motor poison but also a direct heart-poison.

Fellner examined also the influence of hydrastis upon the uterus, and found that after each injection of the drug into the external jugular vein the uterus appeared strongly injected simultaneously with the primary fall of the blood-pressure, and that during the subsequent rise of the pressure the uterine muscle, and often also the round ligament, presented a powerful contraction, and were completely ischæmic. The contraction and ischæmia of the organ continue as long as the high pressure persists. The movements of the uterus were transferred to a kymographion and registered. After each injection of hydrastis the apparatus showed the contractions of both fundus and the horns. The maximal effect was obtained with the first rise and fall of arterial pressure, though contractions, especially in the horns, set in later.

Besides the fluid extract, Fellner examined also two alkaloids of hydrastis and their salts, viz., berberine and the phosphate of berberine, and the muriate of hydrastine. These preparations produced likewise very energetic uterine contraction.

Though with us the high usefulness of

golden seal has long been an established fact, the above credentials bestowed upon the remedy after the vigorous examination in the Vienna laboratory will naturally tend to increase our estimation of the drug and the popularity it now enjoys.

In conclusion, we have to mention the favorable results obtained with the fluid extract of hydrastis by Dr. Shiwopiszew, of Moscow, as published in the *Medicinskoje Obosrenje*, No. 14, 1885. This physician describes eight cases of metrorrhagia (in metritis and endometritis), and of excessive menstrual discharges, in which the fluid extract was given in 20-drop doses four times daily with very satisfactory results. In two cases of metrorrhagia caused by fibromata, and a case of a uterine carcinoma, the remedy failed, while in every other case, where the bleeding was the result of inflammatory conditions of the parts, the exhibition of golden seal proved a success.

This author emphasizes also the remarkable beneficence which the drug impressed upon the tone of the digestive apparatus. He noted that under its use the dyspepsia, the usual incumbent of uterine disease, disappeared, and does not hesitate to confer the epithets of a tonic and a digestive upon hydrastis canadensis.

#### HOPEINE.

IN our April issue we called attention to what seemed to be an attempted fraud in putting on the market, under the name of hopeine, what was practically nothing but morphine, and the view which we then took has since been greatly strengthened by the account of the analyses published in the *Pharmaceutical Journal and Transactions* for April 7, 1886, by Dr. B. J. Paul. He also found that the so-called hopeine was so closely analogous to morphine that, if not identical with it, there was no possibility of distinguishing one from the other in comparative trials. Williamson, the discoverer of this so-called alkaloid, himself acknowledged the similarity of the two bodies after the fact had been proved by other observers, and attempted to explain it by the statement that there was also present in hops, together with this alkaloid hopeine, another alkaloid isomeric with morphine. Now, it would seem from Dr. Paul's results that the hop plant not only contains hopeine and morphine, but also cocaine, for he has found that thirty per cent. of this alkaloid "hopeine" corresponded in

every respect with a good sample of cocaine. It also presented the physiological character of cocaine, producing numbness of the tongue. When boiled with water, it was converted into a fine crystallizable substance,—that is, a product of the decomposition of cocaine in that way; then by boiling for two or three minutes with a small quantity of caustic potash, it was decomposed with the formation of benzoic acid, and, on addition of hydrochloric acid, benzoic acid was separated. This test for cocaine is under certain limitations decidedly characteristic. The general result at which Dr. Paul arrives is, that the greater part of the substance of hopeine is really morphine, and that if it be not morphine obtained from opium, it is so like morphine derived from that source as to be undistinguishable from it. Therefore, if the discoverer's account of it be correct, we must suppose that hops as well as opium contain morphine, although trials made with hops grown in England and other parts of Europe have in common no results showing the presence of morphine. As Dr. Paul puts it, we have to adopt one of two alternatives in this matter,—“Either in the wild hop of America there is a remarkable association of two alkaloids known to occur in two extremely different plants, or we have a case of an article improperly put forward as a substance of natural origin, though really a fictitious mixture.” We leave to our readers to decide which of these two alternatives is the more probable. In the discussion which followed the reading of this paper before the Pharmaceutical Society, two of the members stated that, although they had not absolutely proved it, they were confident that hopeine also contained a trace of atropine, while still another, in giving possibly the strongest testimony as to the nature of this substance, stated that he had been informed that day that the office of the company which had brought forward this substance was closed.

#### ON TUBERCULOSIS OF THE ORAL MUCOUS MEMBRANE.

THOUGH, according to our present views, the tubercular infection may seize upon any organ or part of the system, there are some few localities in which hitherto no tubercular lesions have been found, or, possibly, have not been recognized as such. The crucial test of discovering the tubercle bacillus

would, of course, preclude at present any diagnostic error. On the other hand, it would be scarcely justifiable to deny the tubercular character to a neoplasm on the ground that no tubercle bacilli have been found in it, for every microscopist knows how difficult the detection of the bacilli is in the chronic tubercular processes, in which but a few microbes at best are detectable. Still, it is claimed that, with a certain ample experience, this detection is feasible in every case.

In the *Wiener Med. Bl.*, No. 8, 1886, we find a discussion of several cases of tuberculosis of the mucous membrane of the mouth. One of the cases, all which leave no doubt as to the correctness of the diagnosis, is an especially interesting one. A man suffered from tuberculosis of the lungs, and, as usually, succumbed ultimately to this affection. A tubercular ulcer on his gum proved the medium of propagation of the affection from husband to wife. A few years after the man's death the widow noted the appearance of an ulcer on her lips, which proved to be of a tubercular nature. Direct infection through kissing was in this instance the evident source of this ulcer. After all therapeutic interferences (including cauterization with lactic acid) had proven useless, the ulcer was cauterized with the Pacquelin cautery and disappeared.

The following case, observed by Prof. Petersen in Kiel, is likewise interesting. The patient, a man of 65 years of age, presented a very cachectic appearance and obvious symptoms of phthisis. Some years ago the man had at the tip of his tongue an ulcer,—a cancer, according to his own expression,—which was extirpated and never returned. At the time of presentation the man showed on the mucous membrane of his left cheek a rifted ulcer of the size of a five-cent piece, with a hard base and irregular thickened margins. No nodes could be detected, and no pain was experienced in the ulcer, which had existed for about half a year, and grew very slowly. The appearance and origin of the ulcer and the cachexia of the patient spoke in favor of the diagnosis of carcinoma, while the existing phthisis and the previously extirpated ulcer of the tongue awakened the suspicion of tuberculosis. There was no clinical way to establish the correct diagnosis, but the extirpated and hardened ulcer revealed on a microscopic bacteriological examination its true nature, viz., that of tuberculosis.

Syphilis and carcinoma comprise the principal possibilities of diagnostic erring in the

case of oral tuberculosis. In the former case, as Hansemann aptly remarks in a recent issue of *Virchow's Archiv*, it matters little to the patient whether the extirpated growth is of a carcinomatous or of a lupous tubercular nature, while in the latter perverted therapeutics will probably make mischief. On the other hand, a timely recognition of the tubercular nature of the growth, if originating primarily and still localized, may suggest a medication not altogether void of good prospects. Hansemann quotes four cases of oral tuberculosis, all diagnosed properly *intra vitam* by microscopic examination after an explorative operation. This procedure must after all be regarded as the only infallible way to gain the right diagnosis. Age and cachexia are anything but reliable diagnostic guides, for carcinoma may exist without and syphilis with a cachexia, and besides, syphilis is also found at an advanced age.

#### WHY MR. LAWSON TAIT IS OPPOSED TO VIVISECTION.

A PLAUSIBLE explanation of Mr. Lawson Tait's well-known passionate opposition to vivisection is suggested by Professor F. Winckel in the introductory chapter of his recent excellent text-book on the "Diseases of Women" (*Lehrbuch der Frauenkrankheiten*, Leipzig, 1886).

Professor Winckel raises a voice of warning against laparotomy as a panacea for all the diseases of women. Ovarian tumors and uterine fibroids have ceased to be the only indications for laparotomy. Tubal enlargements, ovarian neuralgia, adhesions of the pelvic viscera, displacements of the uterus, such as retroflexion, prolapse, inversion, have been proposed and accepted as indications for abdominal section. It is possible to go still further, and say that when women suffer from pains in the pelvis, through a considerable period of time, which are not very soon alleviated by ordinary means, the gynecologists resort at once to laparotomy.

"A sadder proof of this statement cannot be adduced than the list of normal castrations presented by Lawson Tait before the International Medical Congress in London, August, 1881. This is really the same thing as to practise animal experimentation upon the living woman, and, therefore, it is not at all remarkable that Lawson Tait is such an energetic opponent of vivisection."

## Reports on Therapeutic Progress.

### THE TREATMENT OF NASAL AND NASOPHARYNGEAL CATARRH.

DR. J. SOLIS-COHEN (*New York Med. Journ.*, April 3, 1886) believes that the two great principles in the treatment of nasopharyngeal catarrh are to keep the parts clean, so as to let them have a chance to get well by themselves, and to take care of the patient's general health; and he believes that this plan will give quite as satisfactory results as when boring, cutting, snaring, and electric cauterization are practised.

The plan he has long used for getting at concealed parts for the purpose of cleansing them, and for the purpose of making any local applications that may be necessary, is to take a small piece of compressed sponge, cut it very thin, moisten it, and place it between the septum and the turbinated bones. The patient sits awhile with this sponge in position, so that, by compression as it imbibes moisture, it is possible to reduce the swelling of the tissues, and thus get a considerable passage for further manipulation. Through the passage thus gained he then uses compressed laminaria tubes, the same kind as are used for dilating the neck of the uterus. These are employed for the purpose of exercising as equable compression on the parts as possible, on exactly the same principle that one exercises pressure by bandaging. They are first to be softened in water, and then to be flattened from side to side, so that they shall become adapted to the shape of the passages. Of course, the size is to be regulated in accordance with the size of the passage. The tent or tube is then allowed to dry after having been flattened, and of course it becomes much smaller. When it is desired to use the tube, after having made a little start in dilating the passage with the compressed sponge (or, in suitable cases, without using the compressed sponge), the tube is greased well with cosmoline, inserted into the passage with the string outside, so that it cannot get loose, and the patient allowed to wear it for an hour or so, according to circumstances. Every half-hour the patient moves the tube a little, and this testing is continued until there is some difficulty in the removal, and then it is withdrawn entirely. It is necessary for this to be done promptly, because these tubes swell up so behind the compressed parts, if left too long, that there may be a great deal of difficulty in removing

them, and so much unnecessary pain be produced. Therefore, just so soon as there is any difficulty in removing them, they have to be taken out. This manipulation is repeated from day to day, and just as soon as the patient has learned it, as he readily does, he does it daily at home. After the first two or three times this compression goes on a great deal better, and then with the sprays, douches, washes, or what not, the parts are cleansed, and, if necessary, other applications made to the surfaces as may seem proper. In the treatment of naso-pharyngeal catarrh where there is a good deal of secretion, the syringing is done partly through the nose and partly through the mouth. Dr. Cohen thinks usually you can wash those parts as well through the nose as through the mouth. But the great point is the cleansing of the parts from the secretions and keeping them clean, for the same reason that one would keep the teeth clean. It sometimes consumes a great deal of time. He has often, in the first interview with the patient, occupied an hour in getting the parts cleansed. The parts must be examined from time to time anteriorly and posteriorly to make sure they are cleansed. Once thoroughly cleansed, the treatment consists in keeping them clean. He has had patients who have told him their malady was of forty to forty-five years' standing, and who have been relieved and have remained relieved for a number of years. Of course exacerbations take place.

#### A SIMPLE METHOD OF ARTIFICIAL RESPIRATION.

The desideratum at which we aim in artificial respiration is to obtain a method of as simple a character as possible, so that it may be readily understood by the laity, and at the same time should possess the maximum efficiency. The main indications in artificial respiration are: first, to loosen clothing, braces, etc., so as to allow free movement of the chest and prevent constriction of the neck; second, to bring the trachea, larynx, and pharynx as nearly as is anatomically possible into a straight line with the openings of the mouth and nose; third, to obtain as deep an inspiration as possible by elevating the ribs and depressing the diaphragm; and, fourth, to get a deep expiration. Now, although the accepted modes of restoring respiration have proved very successful in trained hands, yet they are almost unknown to the general public, and all require a certain

amount of skill, which cannot always be looked for at the hands of the laity. MR. JOHN ARTHUR FRANCIS proposes, in the *British Med. Journ.*, March 20, 1886, a plan which he believes combines all the advantages, without the disadvantages, of the methods generally employed, besides possessing great simplicity. It is as follows: The body, having been laid on the back, and with the clothes loosened and the mouth and nose wiped out, two bystanders should pass a narrow lever of any kind under the body at the level of the waist, and raise it till the tips of the fingers and the toes of the subject alone touch the ground; count fifteen rapidly; then lower the body flat to the ground, and press the elbows to the sides hard; count fifteen again; then raise the body again for the same length of time; and so on, alternately raising and lowering. The head, arms, and legs are to be allowed to dangle down quite freely when the body is raised. A child can easily be manipulated by one person with a hand under each loin. For an adult, the best way is for two persons to grasp each other's right hand under the body, and then raise it. A stout walking-stick or umbrella would be efficacious, where the operators were too weak to lift up the patient with one clasped hand. To join both left and right hands with those of another person would probably form too great a plane for the body to rest on, except in the case of a very tall patient, and prevent the full extension of the spine.

#### THE OPERATIVE TREATMENT OF FACIAL NEURALGIA.

DR. GEORGE R. FOWLER publishes in the *Annals of Surgery*, April, 1886, an elaborate paper on the above subject, from which he draws the following conclusions, as embodying the result of the experience of surgeons up to the present day:

1. Neuralgias of the fifth cranial nerve, of peripheral origin, which have resisted methods of treatment other than operative, may be expected to yield to the operation of neurectomy of the trunk or trunks whose branches are distributed to the painful area. In this class of cases the neurectomy should be carried, if possible, to the point at which the nerve makes its exit from the cranium.

2. Cases of central origin should be first submitted to a limited neurectomy, conjoined with nerve-stretching, in the hope that the process of degeneration thus set up, together with the rest gained by interrupting the cen-

The largest number of reported cases of intubation of the larynx for pseudo-membranous laryngitis have been performed by Dr. F. E. Waxham, of Chicago, who has had seventeen cases with eight recoveries; Dr. Dillon Brown reports fifteen cases with four recoveries; Dr. E. F. Ingalls, two cases, both fatal; and Dr. W. P. Northrup, one successful case. In addition to these, Dr. A. B. Strong has employed the method with success in one case of acute catarrhal laryngitis.

These are all the published statistics which the editor of *The Medical Record* (April 24, 1886) has been able to discover in a somewhat hasty search, and, excluding the case of catarrhal laryngitis, we have thirty-five operations with thirteen recoveries, or slightly over thirty-seven per cent., certainly a very favorable showing, when we consider that nearly one-half of the cases were foundlings, and many of them infants.

If now we turn to the results of tracheotomy we find a smaller percentage of recoveries, taking the statistics of a hospital and private practice together, as has been done in the case of intubation. Gay states that of two hundred and six cases of tracheotomy performed for croup in the Boston City Hospital during twenty years there were sixty-five recoveries, about thirty-one per cent., and in his own practice he has had twenty-nine recoveries in eighty-six operations, nearly thirty-four per cent. Of seventy-seven cases operated upon during the year 1885, in the same institution, Lovett states that twenty, or nearly twenty-six per cent., recovered. These results are not very different from those formulated by Agnew in a study of upward of eleven thousand cases, and we may therefore assume the average percentage of recoveries after tracheotomy to be not far from thirty, although Solis-Cohen is disposed to regard the operation in a less favorable light, notwithstanding his own brilliant series of successes.

We thus find that Dr. O'Dwyer's method already compares very favorably with tracheotomy as regards the saving of life, while certainly, to consider it from an æsthetic point of view, it is much to be preferred. It is, however, too soon to pronounce absolutely upon its merits, for the figures are too small and the operators too few to serve as anything more than an encouragement for further trials. It is only after a method has become in a measure popularized, and the number of cases has mounted into the hundreds, that we can form an adequate judgment of its worth. But if

intubation of the larynx proves itself to be as valuable as these first essays would lead us to hope, it will be accounted one of the great advances in this age of medical discoveries, and we may only wish that such will be its fate.

#### IODIDE OF SODIUM VERSUS IODIDE OF POTASSIUM.

The disadvantages attending the employment of the iodide of potassium have long been noticed and commented upon in England; but, probably from the fact that the other iodides have never come into anything like general use here, these disadvantages have been supposed to result from the exhibition of an iodide as such, and therefore likely to follow the administration of iodides of other bases than potassium. The subject has, however, been taken up and studied of late in a more scientific manner, especially abroad, and we are thus enabled to judge on other than empirical grounds the relative advantages of the different iodides.

The object with which any drug is given is, or should be, the relief of certain definite symptoms; but it need scarcely be remarked that no drug, so far as one is enabled to judge, ever corresponds so exactly to any particular morbid condition as to cover that particular pathological area and no more. The effect of the drug overlaps the diseased area, so to speak, and produces, or is apt to produce, a train of symptoms not only unnecessary and undesirable, but oftentimes positively injurious. Now, when iodide of potassium is given in any beyond quite small doses—and large doses have lately been recognized as indispensable to the relief of many cases where no improvement has been effected by the smaller doses—various troublesome consequences are to be noticed, first among which is an extreme depression. We may here recall the well-known fact that potassium, and all salts into the composition of which it enters, exert this depressing influence, lowering the blood-pressure and slowing the heart. So marked is this action on the heart that large doses (1 ounce and upwards) would probably cause dangerous, if not fatal, syncope, were it not for the fact that its emetic action is so far constant in these doses as to obviate the risk of its being absorbed in quantities sufficient to show its power in this direction. The depression, nevertheless, is always present to some extent, and must often be undesirable. Sodium and its salts are comparatively exempt from this ill effect; and, there-

fore, *ceteris paribus*, the use of the sodium iodide is indicated wherever we think proper to employ large doses of an iodide, or where the state of the patient is such as to render further depression unadvisable. In support of the argument that the depression is the effect of the salt, as a potassium compound and not as an iodide, the following experiments may be adduced. When muscular tissue is cut out of the living body and placed in a two or three per cent. solution of a potassium salt, the chloride, for example, the muscular fibres immediately lose their irritability. If this exposure to the potassium salt be not continued for too long a time, immersion in a solution of sodium chloride will restore to the muscle its irritability. Further, if healthy muscular tissue on removal from the living body be immersed in a solution of chloride of sodium, its irritability will be preserved for a much longer period than if it be immersed in pure water (Kühne). The salt-frog, common in the physiological laboratory, is a practical instance of the stimulating action of solutions of sodium chloride upon the living animal tissue.

Second in the list of inconveniences following the employment of iodide of potassium comes the collection of symptoms, catarrh of the conjunctival, naso-pharyngeal, and respiratory mucous membranes, and headache, known as iodism; and this is not uncommonly accompanied by catarrh of the gastro-intestinal mucous membrane, giving rise to epigastric pain and discomfort, dyspepsia, and diarrhoea. An analytical study of the physiological effect of the drug will show that the catarrh of the gastro-intestinal mucous membrane is probably due to the potassium of the salt, which produces the effects alluded to above, on coming into contact with the muscular walls of the stomach during absorption. For this reason, the drug will often be tolerated if the precaution be taken to give it largely diluted with an alkaline mineral water. The coryzal symptoms are probably due to the iodine component of the salt; it is only of minor importance so far as the general health of the patient is concerned, and is variously accounted for by different authorities. The only theory as to its etiology which we shall mention is the one advocated in the latest edition of Nothnagel and Rossbach. According to these authorities, the catarrh of the nasal and respiratory mucous membranes occurs only when either free iodine is used externally together with the iodide of potassium internally, or when the potassium iodide which

is used is impure from the presence of some free iodine; in either case, it is the direct irritation of the free iodine, either in the process of excretion or when inhaled as a vapor, which causes the catarrh. If this be so, these effects will be avoided by care being taken to administer a pure potassium or sodium iodide. What has been said as to the cause of the catarrh will hold good for the eruption also; the latter is the external manifestation of an irritation of the integument, just as the former is of irritation of the mucous membranes.

We are ignorant, it is true, of the exact mode of action of the iodides, and of the iodide of potassium in particular; our employment of it is empirical, and we are reduced to the vague designation of "specific" to describe its therapeutical effect. If this be the case in speaking of its action in cases of tertiary syphilis, how much more applicable is it when employed as an "alterative" or "resorbent," where its *modus operandi* can scarcely be guessed at. Be this as it may, whatever effect can be attributed as a "specific" to iodide of potassium can probably with equal justice be credited to the other iodides, and particularly to iodide of sodium; while, as we have endeavored to show, the inconvenience resulting from the employment of an iodide in large doses, is minimized by the substitution of sodium for potassium salts. The same remarks apply with few reservations to the analogous salts of bromine. Such authorities as Nothnagel and Rossbach assert that they have used the sodium iodide almost exclusively for some years past where the drug had to be given for a long time, with results equal to those obtained from the iodide of potassium; and Dr. H. W. Berg, of New York, has used it with similar good results in cases of pregnant women under the influence of syphilis.

To sum up, then, we may claim for sodium iodide that (1) it can be used therapeutically for almost all, certainly the chief, purposes for which potassium iodide is used, and with similar beneficial results; (2) that sodium iodide is more assimilable than the iodide of potassium, both locally to the digestive organs and to the general system; (3) that, as a result, many of the local and general undesirable effects which are produced by the potassium iodide do not follow the use of the sodium iodide. It is to be hoped, therefore, that the sodium iodide will be used by those whose clinical advantages allow an extensive trial of the drug, so that a more extended ex-

It is to be hoped, therefore, that the sodium iodide will be used by those whose clinical advantages allow an extensive trial of the drug, so that a more extended ex-

perience may confirm that which a limited experience seems to claim for this drug.—*British Med. Journ.*, April 17, 1886.

**SYNCOPE AS A CAUSE OF ASPHYXIA  
NEONATORUM, AND ITS  
TREATMENT.**

DR. GEO. H. NOBLE (*Amer. Journ. of Obstetrics*, April, 1886) believes that anæmia of the brain is in nearly all cases the cause of asphyxia neonatorum, and that, therefore, inversion of the child, by which means the blood tends to gravitate to the brain, will in many cases serve to restore children to life which are apparently dead, and in which artificial respiration will ordinarily fail. He therefore recommends the inversion of the child, or, in other words, placing the head lower than the body, and claims for it the following advantages:

1. It enables one to employ any other method in connection with it.
2. It is totally void of violence,—a matter well worthy of consideration. Violent or prolonged artificial respiration works much detriment, and may even fan out the last spark of life.
3. It induces the escape of such fluids as may be in the air-passages,—a matter of prime importance, especially in cases of intra-uterine respiration.
4. Where there is a circulation of blood through the foramen ovale, it substitutes the purer blood of the vena cava ascendens for the venous blood of the vena cava descendens.
5. It gravitates the blood to the lungs, which, there distending the blood-vessels, causes additional stimulus to respiration.

**INHALATIONS OF COLD AIR IN ENTERIC  
FEVER.**

In the beginning (*London Med. Record*, March 15, 1886) of his work, DR. ALEXANDER M. SOKOLOFF, of the Krasnoselsky Military Hospital, makes an interesting observation (*Voënnno-Méditz. Jour.*, February, March, May, June, and July, 1885, and the *St. Petersburg Inaugural Dissertation*, 1884, p. 116) that though typhus patients at this hospital in summer-time are kept in tents, where during August and September the temperature by nights sometimes falls as low as  $+6^{\circ}$  C., and even  $0^{\circ}$  C.; and though under these circumstances the temperature of the patients in many cases falls from the evening height of  $40^{\circ}$  C. to the

normal in the next morning, he has never seen anything like dangerous collapse or other complications. Starting from this observation, the author justly remarks that dry cold air as a therapeutic agent has not, as yet, attracted the due attention of medical men, in spite of the recommendations made by Hahn, Rosenthal, Senator, Kaczorowski, Langenbeck, and P. Niemeyer. Meanwhile, the statements of the authors named recently found a confirmation in the careful experiments made by Dr. L. R. Trautenberg, in Professor V. A. Manassein's clinic. Dr. Trautenberg, however, while admitting the therapeutic value of cold-air baths, at the same time has pointed out that they—as an antipyretic—occupy a lower level comparatively with cold-water baths.

Searching for some means of intensifying the antipyretic action of cold air, Dr. Sokoloff resolved upon undertaking a series of experiments on inhalation,—that is, on introducing this cooling agent directly into the lungs, into “one of the regions of maximal heat-formation.” His observations were made in twenty-three cases of enteric fever, five of which were of an abortive type, the remaining eighteen being moderately or very severe (two ended fatally). The patients were made to inhale from a Niemeyer's cold-air inhaler, slightly modified by the author. About five hundred and ten inhalations were made in twenty-three cases, the number of sittings in an individual case varying from six to forty-two; the number of sittings daily from one to three; the duration of a sitting from five to thirty minutes; and the temperature of the air from  $-2^{\circ}$  to  $-10^{\circ}$  R ( $27.5$  to  $10.5^{\circ}$  F.). From these observations the author draws the following conclusions:

1. Inhalations of cold air produce a greater or less depression of febrile temperature; but, contrary to the author's expectations, their effect is comparatively weaker and more fleeting than that of cold-water baths, and even of cold-air baths. The antipyretic effect of the inhalations varies according to certain conditions.
  - a. *The time of the day.*—The least decrease of the febrile temperature, varying from  $0.2^{\circ}$  to  $0.5^{\circ}$  C., is observed when the inhalations are made between noon and 6 P.M. The strongest effect, varying from  $0.5^{\circ}$  to  $1.3^{\circ}$  C. (after a single sitting), is observed between 7 P.M. and 10 P.M.
  - b. *The stage of the disease.*—The slightest and shortest effects are observed during the first two weeks of enteric fever, when the average daily decrease (after several sittings) falls short of  $1^{\circ}$  C., and when the effect of an individual sitting does not

last longer than one and a half to two hours. During the next weeks of the disease the effects are stronger (often  $1^{\circ}$  C., after a sitting), and last several hours. *c. The duration of the inhalation* is of but slight importance. A sitting of five to ten minutes' duration gives the same decrease of the febrile temperature as a sitting of twenty minutes' duration. The author attempts to explain this rather strange circumstance by fatigue of the lungs, in consequence of which the patient makes accelerated and superficial respiratory movements. At all events, the greatest antipyretic effects are obtained from sittings of twelve to fifteen minutes' duration. *d. The temperature of the air inhaled.*—A temperature of  $-2^{\circ}$  or  $-3^{\circ}$  R. gives almost the same decrease of the febrile temperature as the temperature of  $-4^{\circ}$ ,  $-5^{\circ}$ , or  $-6^{\circ}$  R. Relatively stronger effects are obtained from temperatures of  $-8^{\circ}$ ,  $-9^{\circ}$ , or  $-10^{\circ}$  R. It would seem natural to expect *a priori* that the antipyretic effect ought to be greater the lower is the temperature of the air inhaled. It proved, however, otherwise. The relatively small effect of lower temperatures is attributed by the author to a comparatively shorter duration of the sittings, the patients being unable to perform prolonged inhalations on account of unbearable toothache occurring in consequence of intense cooling of the mouth and teeth. *e. The mental state of the patient.*—Both depression and excitement (often observed in typhus patients) diminish or even entirely suppress the antipyretic effect of the inhalations.

2. The inhalations produce retardation of respiration (in average, four a minute) and pulse (in average, six beats a minute). At the same time, breathing becomes deeper and the pulse fuller.

3. The inhalations relieve dryness of the mucous membranes and skin.

4. Inhalations of cold air promote resolution of the bronchitis which often complicates enteric fever, and increase the process of ventilation in the lungs.

5. Hence the inhalations lead to an improvement in the patient's general state, sleep, and appetite.

6. Inhalations of cold air act antiphlogistically on the inflamed respiratory tracts, and hence may be employed as a rational therapeutic agent in the treatment of pulmonary inflammation.

7. Systematic inhalations of cold air may prove of use also in chronic bronchitis, asthma, and emphysema.

#### TREATMENT OF OBSCURE FORMS OF METRORRHAGIA.

At a meeting of the Harveian Society, held April 1, 1886, DR. ARTHUR W. EDIS read a paper on the treatment of obscure forms of metrorrhagia (*Lancet*, April 10, 1886). He urged the importance of regarding hemorrhage merely as a symptom of some constitutional or local disorder, and not as a disease or entity *per se*. It was a conservative effort of nature in many instances to lessen the arterial tension and prevent the occurrence of more serious internal hemorrhages. A correct diagnosis was the first and most important element of successful treatment, for until the former be known the latter is mere guesswork, and we are as liable to do harm as good in attempting to repress the hemorrhage. The principle of diagnosis by exclusion was one which approved itself to many,—determining, in fact, to what cause the hemorrhage was not due. This could only be done by knowing beforehand what were the most likely causes of severe hemorrhage,—the *possibilities*, so to speak, and then eliminating one after the other until we have left only two or more *probabilities*. Before concentrating attention upon the probable local disorder, the possibility of some complicating constitutional condition, whether cardiac, renal, or hepatic, should always be considered. A clear and concise history of the attack was of great importance in attempting to arrive at a correct diagnosis. Then, again, the color and consistence of the discharge should be noted: whether bright or dark, fluid or clotted, recent or disintegrated. The duration of the flow, interval between the losses, influence upon the general health, and other similar considerations, should not be passed over. Unsuspected miscarriages and incomplete abortions proved a not inconsiderable percentage of these obscure cases. Some of the most difficult cases to diagnose occurred at or about the so-called climacteric period. Exploration of the interior of the uterus, either by dilating or excising the cervix, should always be resorted to where no sufficient outside cause for the hemorrhage could be detected. Cases illustrating the difficulty of forming a correct diagnosis were given, and the lines of treatment sketched out.

#### THE ALKALOIDS OF LOBELIA INFLATA.

The discovery of a second alkaloid in the leaves of *lobelia inflata* has been an indirect result of an examination of the *lobelia nicotianæfolia*, a plant growing in the mountain

ranges of the Madras peninsula and Ceylon. One of the Mahratta names of the latter plant is "the tubular poison plant," and an infusion of its leaves is said to be used by the natives as an antispasmodic. It is mentioned in the Indian Pharmacopœia, and Dr. Dymock, in his "Vegetable Materia Medica of India," says that the leaves resemble tobacco, and that the dry herb, when handled, is extremely acrid, the dust irritating the throat and nostrils. As nothing was known concerning the active constituents of this drug, its examination was undertaken in the University of Dorpat by HERR VON ROSEN, who reports (*Thesis*) that he has isolated from lobelia nicotianæfolia two alkaloids,—one a liquid, and corresponding with the reported properties of lobeline from lobelia inflata, and the other a crystalline solid, soluble in chloroform, and difficultly soluble in water, the chemical properties of which are under investigation. Herr von Rosen was therefore induced to make similar experiments on lobelia inflata, and succeeded in separating from that drug also both the liquid and the solid base. The results of some pharmacological experiments made with lobeline hydrochlorate, prepared by Herr von Rosen from the two plants, a commercial sample of lobeline sulphate, and that solid alkaloid from the two plants, showed that they corresponded completely in their action, which resembled apomorphine in its emetic character.—*Pharm. Journ. and Trans.*, April 3, 1886.

*THE INFLUENCE OF KAIRIN, THALLIN, HYDROCHINON, RESORCIN, AND ANTI-PYRIN ON THE HEART AND BLOOD-VESSELS.*

It is through the agency of the blood-vessels and the blood which circulates within them that not only the temperature of the various organs of the body is constantly being equalized, but also that the superabundant heat is thrown off. As is well known, the constant or normal temperature peculiar to animals depends upon the maintenance of a proper balance between the amount of heat generated within the organism and the amount given off to the surrounding medium through the agency of the blood-vessels of the skin, the lungs, etc. Thus, when heat-production is feeble, and the temperature of the surrounding medium low, the cutaneous vessels will be found contracted, and the amount of blood which flows through them in a unit of time will consequently be relatively small. On the other

hand, these vessels will be found dilated, and an abundant flow of blood take place through them, when heat-production is increased and the temperature of the surrounding medium is high. Hence, it is evident that any interference with this important function of the circulatory apparatus must necessarily greatly influence the temperature of the body, and anything tending to lower the tone of the blood-vessels, or weaken the heart's action, at once deprives the organism of its most effective means for heat regulation. In the condition known as fever, the temperature peculiar to the animal, or its normal temperature, exists no longer, and in place of it we find a higher one. All the drugs named at the head of this article have been found to reduce the abnormal temperature to a greater or less degree, and yet until now there has been made no detailed series of experiments as to the influence of these remedies on the circulatory apparatus.

It is evident that in the explanation of the action of these drugs, such as antipyretics, this point must first be considered, and conclusions, which must be of the greatest value, may be drawn from the experiments published by DR. H. G. BEYER in the *Amer. Journ. Med. Sci.*, April, 1886. His experiments were made on the frog and terrapin, and he studied the action of the drug on the isolated heart and on the blood-vessels. His results may be formulated about as follows:

I.

1. Kairin produces dilatation of the capillaries and veins, which dilatation much exceeds that of the arterioles, which latter is sometimes preceded, sometimes followed, by an abnormal contraction.

2. It causes a slight acceleration in the current in the arterioles and a slowing of the flow in the small veins.

All the experiments made with kairin on the heart (nine in number) show the great weakening effect it exerts upon the contracting power of the cardiac muscle.

3. Kairin has a destructive influence upon the hæmoglobin of the red blood-globules, and arrests the movements of the white corpuscles. From the results of these experiments, it is quite clear that kairin reduces temperature, both by diminishing heat-production and by increasing heat-radiation. The distinctive influence it exerts on the red blood-corpuscles, however, and the weakening effect upon the heart, render its employment objectionable and dangerous.

## II.

1. Thallin, in comparatively small doses, slightly increases the rate of the heart, and considerably increases the work done.

2. Larger doses decrease both the rate and the work done, finally producing diastolic arrest.

3. Atropine retards but is unable to prevent this result.

4. Repeated thallinization of the heart is followed by a peculiar shrinkage of the entire organ, during which it presents the dark color of thallinized blood.

5. The order in which the different parts of the heart are affected is the same for the terrapin as for the frog. To this must be added that the injection of a one per cent. solution of thallin into the substance of the ventricle produces systolic arrest within a few minutes.

6. Thallin, in comparatively small doses, produces dilatation of the arterioles, followed by a contraction of the same.

7. It produces dilatation of the capillaries.

8. It causes a much greater and much more permanent dilatation of the small veins than of either the capillaries or arterioles.

9. Under thallin venous blood and the walls of the veins assume an abnormally dark color.

Thallin, like kairin, reduces temperature by diminishing heat-production and by increasing heat-radiation. As an antipyretic, it is less dangerous, but no less objectionable, than kairin, for while its effect upon the ventricle of the heart is less depressing than that of kairin, its influence upon the blood-corpuscles is sufficient to condemn it.

## III.

1. Small doses of hydrochinon in the frog reduce the rate of the heart and the amount of work done.

2. Larger doses quickly paralyze the great veins, sinus, and auricles in the order in which they are named, while the ventricle is affected but slightly.

3. Increasing venous pressure will materially hasten this occurrence.

4. In the terrapin small doses of hydrochinon slightly increase the amount of work done by the heart, but reduce its rate.

5. Larger doses rapidly reduce both rate and work, finally arrest the auricles and sinus in diastole, the ventricle, though much weakened, not being affected to that extent; the ventricles recover quickly and completely, the auricles slowly and imperfectly.

6. Hydrochinon produces dilatation of the arterioles and capillaries, which dilatation is followed by an abnormal contraction.

7. It causes dilatation of the small veins, which dilatation is much more extensive and lasting than that of either the capillaries or arterioles.

8. It quickens the flow in the arterioles and slows it in the veins.

9. It imparts a deep purplish color to the blood flowing in the veins.

10. The effect is the same, whether hydrochinon is injected hypodermically or is used externally. When injected, muscular twitchings come on, which necessarily interfere with the study of the vessels of the tongue.

From all these experiments made with hydrochinon on the heart and blood-vessels of the frog and terrapin, we must arrive at the conclusion that it reduces temperature mainly by increasing heat-radiation, owing to its influence upon the veins, which it largely dilates, and the capillaries and arterioles, which it also dilates, though to a less extent.

## IV

1. Resorcin, in small doses, improves the heart's action.

2. In doses of medium size, it paralyzes the sinus and auricles, but has little effect on the ventricle.

2. In very large doses, it at once causes diastolic cardiac arrest, the ventricle recovering sooner or later, the auricles rarely ever.

As is the case with kairin, thallin, and hydrochinon, resorcin reduces the rate of beat of the heart, probably by a stimulating influence on the terminal filaments of the pneumogastric, and dilates the vessels through a similar influence on the ganglia of the vaso-dilators. The tonic effect which it has upon the ventricle is most probably due to its direct action upon the muscular substance of the heart. We have so far no explanation of the difference in the action of these drugs upon the two sides of the heart and vascular system. Nevertheless, the fact remains that all the drugs so far considered possess this property nearly to the same extent. The only difference regarding their influence upon the heart lies in the ventricle. Kairin and thallin, in small doses, exercise but a temporary tonic influence over its contraction. Hydrochinon and resorcin a more permanent one. They all quickly paralyze the auricles and lower the tone of the walls of the veins. The natural consequence is that a much greater quantity of blood will be contained in the veins than in

the arteries, and its passage from the veins back into the ventricle is greatly impeded, owing to the paralyzed condition of the auricles. Collapse therefore ensues; not so much from failure of the action of the ventricle as from the danger of the bleeding the animal to death into its own veins, to use the words of Ludwig.

V.

1. Antipyrin, in very small doses, injected into the lymph-sac of the frog, very slightly contracts the arteries, but dilates the capillaries and veins; in large doses, applied directly to the surface of the tongue, it gives rise to extensive dilatation in the veins and also the capillaries. A one per cent. solution of it applied to the tongue of the frog will, after a short time, cause coagulation in all the superficial blood-vessels.

The manner in which antipyrin reduces temperature is purely by increasing heat-radiation, owing to its extensively dilating the veins and capillaries; but what stamps it as an excellent antipyretic is that, besides dilating the veins, it also has a tonic influence on the heart and slightly increases arterial pressure, or, at any rate, does not cause a diminution of the same. It has, moreover, no injurious influence on the blood or the muscular tissues, and strengthens the auricles.

The objection to the employment of kairin and thallin as antipyretics is from the fact that they cause heart-paralysis, especially affecting the auricles, in doses only slightly larger than are sufficient to produce a lowering of the temperature. But this objection becomes an absolute danger when we take into account the destructive influence upon the blood-corpuscles and tissues generally.

Hydrochinon and resorcin, although not exerting the same weakening and directly paralyzing influence upon the ventricle of the heart which is peculiar to kairin and thallin, both paralyze the venous side of the heart, viz., the auricles, and greatly lower the tone of the walls of the veins. The exact amount of blood, therefore, which is driven into the veins through the increased action of the ventricle is only with great difficulty returned to the ventricle, and here the danger is not so much from failure in the power of the ventricle, as in the case of kairin and thallin, as from the danger of bleeding the animal to death into its own veins. The intense visceral, and especially pulmonary, congestion found on post-mortem by Dujardin-Beaumetz and others, in animals killed by resorcin, seems to confirm this view of the matter.

Antipyrin, though largely dilating the veins, increases the power of contraction of both auricles and ventricle, and has no injurious influence upon the blood nor the muscular tissues, and therefore possesses, indeed, all the good qualities of a perfect antipyretic.

PUNCTURE OF THE NERVE-SHEATH IN SCIATICA.

SIR JOSEPH FAYRER states in the *Practitioner*, April, 1886, that some years ago he was asked to see a case of aggravated sciatica of long standing in a man of middle age. The pain was very severe, continuous, liable to increase, and of a paroxysmal character. The posterior muscles of the thigh were somewhat atrophied. The patient himself was wasted and worn by continued suffering and deprivation of rest and sleep. There was no history of rheumatism, gout, syphilis, or other specific cause. A malarial origin, of course, was possible, but there was no satisfactory explanation of the origin of the disease. All the usual methods of treatment had been resorted to, but without relief. On examining the limb carefully he detected, with some feeling of fluctuation, a fulness and tenderness in the course of the sciatic nerve near its origin in the upper part of the limb. He therefore introduced a long, narrow knife into the swelling until it entered the sheath of the sciatic nerve. This gave exit to a certain quantity, a couple of drachms or so, of clear, serous fluid, which was followed by immediate relief of suffering, and rapidly resulted in complete recovery.

He says that he has seen other cases, none so well marked as this one, however, and with much less effusion of fluid, where incision, or rather puncture, has given relief, but he is not aware of others having similar experience, and would therefore call attention to it as of practical interest.

LACTIC ACID AS A DESTROYER OF PATHOGENIC TISSUES.

Since Mosetig-Moorhof's favorable results with this agent, already alluded to in the *GAZETTE*, various other observers have made use of it in lupus, superficial epithelioma, papillomatous growths, fungous processes, scrofular ulcerations, laryngeal phthisis, etc. Its advocates claim that it is not a true caustic, but selects diseased and spares healthy tissue. Wherever its employment is practical it is consequently to be preferred to curetting.

In the *Annals of Surgery* for March, 1886, DR. W. BROWNING publishes an analysis of the results obtained recently through the employment of this method of treatment.

The acid is a syrupy liquid miscible with water. Though not considered necessary by some, its action may be confined by covering surrounding parts with plasters, collodium, or traumaticin; fats are an impediment. It is applied on linen, felt, or the like, either pure or reduced with water, or mixed as a paste with pure pulverized silicic acid. It may be applied with a brush, but does not then act as rapidly. It is further recommended to bind it on with rubber, paper, or other confining material. It causes considerable pain for a few hours (Bum says one to three), and is usually removed in twenty-four or less.

Joseph (*Deut. Med. Woch.*, 1885, No. 43) cured a leucoplakia buccalis with eighty per cent. diluted lactic acid. Schnitzler reported at the September *Naturforscher-Versammlung* his experience with it—not very favorable—in tuberculosis of the larynx. Krause, of Berlin, has also used it in this affection, and Jellinek (*Wien. Med. Wochenschrift*, 1885, No. 46), in Schrötter's clinic, has for some months given it more thorough trial. For this purpose he prefers a twenty to eighty per cent. solution. The healthy mucous membrane is but slightly affected, while infiltrated portions are slowly destroyed. The more succulent the infiltration the more vigorous the action; œdematous parts shrink in three or four days, and troubles in deglutition are rapidly relieved. Most favorably affected were small ulcerations, especially on the vocal cords; larger sores were only prevented from further growths. In ulcerous, granular, and hypertrophic pharyngitis he had good results. In nasal troubles simple brushing does not suffice; longer contact is necessary. Jellinek believes that in laryngeal phthisis by daily applications more can be accomplished with this than with any other remedy, and that in its earlier stages it can thus be cured.

Bum (*Wien. Med. Wochenschrift*, 1885, No. 47) has for several months been employing it in fungous,—i.e., tubercular disease of soft parts—skin, subcutaneous tissue, lymphatic glands—in dispensary practice. The unhealthy granulations are reduced to an easily reducible pulp; the walls of the cavity do not bleed. After two or three applications, with intermediary pauses of two days, a permanent dressing of iodoform gauze is used, abundant healthy granulations develop, and a smooth, soft scar results. Lactic acid will at-

tack healthy as well as unhealthy epidermis, but in the subdermal tissue it seeks out fungous nests and destroys them. Bum gives short histories of nineteen cases in patients from 1 to 52 years of age. There were eight males and eleven females; eight ulcers, seven fungous and four fistulous. The average number of acid dressings was three, and the average time of cure twenty-five days, or, deducting one who removed dressings, but nineteen and eight-tenths days. No failures, and, up to date, six weeks to five months later, no relapse.

Finally, Mosetig has returned to the subject again (*Wien. Med. Wochenschrift*, 1885, No. 48), with the demonstration of good results in a large facial epithelioma in a man æt. 55, and an ulcer rodens on the face in a woman æt. 60. In the former, he had made twenty-six applications in a month, and in the latter he had made twenty already. In caries, he finds it excellent, good demarcation being produced, and there being less liability to relapse than after curetting. He has tried injections of the acid,  $\frac{1}{2}$  to 1 grm. of a fifty to seventy per cent. solution. Whether relapses may yet occur he, of course, cannot say.

#### IODIDE OF POTASSIUM IN SPASMODIC ASTHMA.

DR. J. ORMROD publishes in the *Practitioner* (April 10, 1886) a tabular analysis of the results obtained in thirty-six cases of asthma treated with iodide of potassium. All of the cases displayed, though with varying severity, the cardinal symptoms of the disease,—that is, difficulty of breathing coming on suddenly, usually in the early morning during sleep, and passing off after a time, so as to leave the patient comparatively well, but recurring usually in a regular fashion at regular intervals. The iodide was given alone, or, if in combination, only after the effect of the uncombined drug had been tried, and it proved a failure only in nine cases out of thirty-six,—that is, in twenty-five per cent., while its good effects were not limited to the uncomplicated cases. Five or ten grains three times a day seemed to suit best in most cases, but in some a larger or smaller dose did better. In some, again, an increase of the dose did good for a time, but the effects seemed to wear off. In confirmed cases the drug can hardly be claimed to be curative, though it will in many relieve attacks, which, however, are apt to return when the use of the drug is stopped.

### DRAINAGE OF IDIOPATHIC INTRACRANIAL ABSCESES.

The evacuation of traumatic abscesses of the brain has long been a recognized procedure, and has met with a fair measure of success. Recently Mr. Hulke has endeavored to extend this practice to idiopathic abscesses within the cranium. A few months ago a man was admitted into the Middlesex Hospital, under DR. CAYLEY, suffering from coma, which had supervened upon a long-standing purulent discharge from the ear. There were no localizing symptoms. Mr. Hulke trephined the skull in the lower part of the temporal fossa, and by means of a director explored the temporo-sphenoidal lobe, without result. The operation was unattended with ill results, but after the patient's death, a few days later, an abscess was found in the cerebellum. Quite recently a woman was under Dr. Cayley's care with similar history and symptoms, and intracranial suppuration was diagnosed. Mr. Hulke determined to explore the brain. In this instance he made an aperture in the cerebellar fossa of the occipital bone, and through a small incision in the dura mater he passed a director through the cerebellum in all directions, but without striking an abscess. Finding that the symptoms were unrelieved, he subsequently trephined the temporal fossa, and opened an abscess in the temporo-sphenoidal lobe. We believe these cases will be duly reported to one of the medical societies. They mark an important advance in cerebral surgery, but further comments upon them must be deferred until all the facts are before us.—*Lancet*, April 10, 1886.

### THE USE OF PAPAÏN IN THE TREATMENT OF DYSPEPSIA.

Papaïn, as appears from the conclusions of Prof. Finkler, has properties which compare advantageously with those of pepsin and pancreatin. As is well known, it is a digestive powder prepared from the juice of *Carica papaya* (melon-tree). 1. It digests equally in acid, alkaline, or neutral fluids, best of all in water. 2. It will dissolve 1000 times its own weight of fresh blood-fibrin. 3. Its action is increased by the presence of pepsin and pancreatin. 4. It acts at the temperature of the body. 5. Meat infused with a solution of papaïn keeps, while undergoing a softening process, much longer than it does without it. From this, it can be inferred that it has an

antiseptic as well as a peptonizing action. 6. The product of its action is a peptone, which, from its properties, may be taken to be Meissner's  $\epsilon$  peptone. 7. Papaïn adheres to albumen to such a degree as to prevent its being removed by protracted washing with water. 8. Papaïn, in contrast to pepsin, acts when the resulting peptone-solution is highly concentrated. 9. The addition of antiseptics, such as salicylic or carbolic acids, does not interfere with its action. Hence, in papaïn (Finkler), we have apparently an ideal digestive ferment.

The principal uses for which papaïn has so far been employed is in the digestion and removal of diphtheritic membranes, but DR. GEORGE HERSCHELL recommends this drug in the treatment of various forms of dyspepsia (*Brit. Med. Journ.*, April 3, 1886). Two preparations of this substance are now on the market (those of Christy and Finkler), which, according to Dr. Herschell, possess considerable difference.

In experimenting with them, and comparing the results, it appears at first sight that the former is much more energetic than the latter; but, on further investigation, it will be seen that this apparent virtue really unfits it for internal use, inasmuch as, not content with converting the fibrin into peptone, it again splits it up into bodies soluble in alcohol, and analogous to leucin and tyrosin, which, so far from being of any use in digestion, are absolutely injurious. It is, therefore, evident that the chemical and medicinal results must be kept apart.

If .01 gramme of papaïn (Finkler) be placed with 10 grammes of fresh blood-fibrin, and 50 c.c. of water, at 45° to 50° C. (113° and 122° Fahr.), and put into an oven of the same temperature, the solution takes place in from forty-eight to eighty hours. If, on the other hand, papaïn (Christy) be used instead, in the same experiment, the solution takes place in a much shorter time. But here an important distinction comes in.

If to the result of each experiment be added 10 grammes of fresh blood-fibrin, it will be found that the papaïn (Finkler) will still dissolve this in twenty hours, while that containing the papaïn (Christy) will not dissolve it at all. This proves that the former is a true catalytic ferment, and that the latter is not. An alcoholic extract of the latter will also show the presence of the leucin and tyrosin-like bodies by the usual tests.

Dr. Herschell finds papaïn chiefly valuable in the chronic stomach-catarrhs of children,

in acid dyspepsia, and in cases where severe gastric pain comes on shortly after eating.

1. *Chronic Stomach-Catarrhs of Children.*—

Every one is familiar with that state in which we find children at times, and which is very frequently called "biliousness." It is characterized by loss of appetite, languor, pasty complexion, loss of sleep at night, and irritability during the day. There is frequently frontal headache, and the urine is loaded with lithates. If this state continue for any length of time the child emaciates, the unhealthy mucus which sheathes the stomach and intestines preventing the due absorption of the food. Cod-liver oil and compound syrup of the phosphates, which are generally given for this complaint as soon as the child begins to lose flesh, are not assimilated. Sometimes a cough develops, and the child is supposed to have incipient phthisis. Dr. Herschell has found these cases rapidly improve with the following prescription: *R* Papain (Finkler), gr.  $\frac{1}{2}$  to gr. i; sacch. lactis, gr. i; sodii bicarb., gr. v. *M.* To be taken after every meal. It is also advantageous to give a drop or two of tincture of nux vomica immediately before the meal in a little water. The papain probably acts by dissolving the mucus, and thus facilitating the absorption of the food.

2. *Acid Dyspepsia.*—This drug is extremely valuable in this form of indigestion. *a.* As it acts equally well in the presence of an alkali, a sufficient quantity of bicarbonate of sodium may be given with it to neutralize the excess of acid in the stomach without impairing its peptonizing power. *b.* Its antiseptic action checks the abnormal fermentation to which much of the accompanying flatulence is due. *c.* An antiseptic can be given with it to increase this action. Dr. Herschell usually orders it in the following manner: *R* Papain (Finkler), gr. ii; sacch. lactis, gr. v. *M.* To be taken an hour after meals with the following draught: *R* Sodii bicarb., gr. xv; glycerin. acid. carbolic.,  $\mathfrak{xxviii}$ ; spirit. ammon. aromat.,  $\mathfrak{xx}$ ; aq. ad  $\mathfrak{ziss}$ . *M.* Fiat haustus. It appears that, taken one hour after a meal, a smaller dose of papain is required to produce the same result than if taken with the food.

3. *Cases where Severe Gastric Pain coming on shortly after Eating is the Prominent Symptom.*—Dr. Herschell has tried the drug upon twelve cases of this nature. Complete relief was given in ten, one case was partially relieved, and one completely failed to derive any benefit.

Apart from its internal use, papain will probably come into extensive use as a peptonizing agent, to prepare ready digested

food and enemata in the way in which pancreatin and pepsin are used at present.

THE USES OF POMEGRANATE-ROOT.

At a recent meeting of the Liverpool Medical Institution, Mr. NICHOLSON (*Med. Press*, March 24, 1886), after giving the history of pomegranate-root as a remedy for tapeworm, related the circumstances of his becoming acquainted in India with its use for other diseases of the bowels. Children are especially liable there to what appears to be tuberculous disease, or, at least, wasting disease, for Mr. Nicholson declined committing himself to an exact classification of the disease. They lose all appetite, become thirsty, peevish, with restless nights; the bowels are deranged, often loose, the belly is tumid, and in many cases the child wastes away and dies. The routine treatment for such a state is generally of no avail. In such cases the greatest benefit was found to result from the decoction of pomegranate-root; not from any anthelmintic properties, but from what may be termed an alterative effect. Several cases had been treated in England, where the disease, though generally unaccompanied by diarrhoea, is one of the causes of those deaths of children which are usually classified as consumption. The remedy had also been found beneficial in some diseases of adults, notably in chronic slight feverishness and debility, attributable possibly to malaria or enlargement of the spleen, though resisting quinine and other usual treatment. Mr. Nicholson had in his first English case been obliged to get pomegranate-root from abroad, but had since used the *elixir granati*, made according to Mr. Siebold's formula by Messrs. Evans & Sons, of Liverpool. It was administered in doses (for young children) of 10 minims, equal to a little more than half an ounce of the P.B. decoction. He had never seen any symptoms of toxic effects from large doses, either of the elixir or of decoction, from quite fresh root in India. The whole root seemed to be equally efficacious with the root-bark, at least for the diseases under consideration.

PROPOSED MODIFICATION OF PIROGOFF'S OPERATION.

At the recent congress of Russian practitioners, PROFESSOR TAUBER described and demonstrated on the dead subject an operation for removal of the foot, which he believes has

several advantages over Pirogoff's amputation. Standing on the outer side of the limb, he commences an incision at the insertion of the tendo Achillis, and carries it forward just below the external malleolus to the dorsum of the foot, and then vertically downwards on the inner side in front of the heel. When the middle line of the sole is reached, the incision is carried along it backwards and prolonged upwards to the starting-point at the insertion of the tendo Achillis, a flap having thus been cut consisting of the inner side and half the sole of the heel. The joint is then opened, the external ligaments being first divided and then the internal. The astragalus is seized with the bone-forceps and removed, and the anterior part of the foot cut off by Chopart's line, nothing being left but the os calcis, the soft coverings of which on the inner aspect are untouched. The os calcis is seized with the bone-forceps and turned so that the articular surface is towards the operator. The forceps are now taken by an assistant, who holds them tightly; the operator then saws the bone longitudinally in two; the outer half, which is free, is removed, the inner half remaining attached to the flap. The ends of the tibia and fibula are then sawn off just above the malleoli. The cut surfaces of these will be found to correspond almost exactly with that of the os calcis, which is now brought into apposition with them. The advantages claimed for this operation are: 1. The posterior tibial artery itself is untouched, only its branches being divided. 2. The insertion of the tendo Achillis, as well as its bursa, are not injured. 3. The surfaces of the os calcis and of the leg bones correspond very nearly to one another.—*Lancet*, April 3, 1886.

#### THE ACTIVE PRINCIPLE OF CALUMBA-ROOT.

Calumbin, the non-nitrogenous crystalline bitter principle occurring in calumba-root, together with berberine, is usually represented as not possessing much physiological activity. Dr. Lauder Brunton says ("Pharmacology," p. 757) it seems to have less action than berberine. But some experiments made with the separated crystalline principle, and reported by M. HOUDÉ, point to it being a somewhat energetic substance, giving rise to vomiting and diarrhoea. In small doses it appeared to augment the secretion of bile, of the glands of the stomach and the intestine. After full doses, the liver appeared to undergo granular fatty degeneration. A dose of 10 centi-

grammes (1½ gr.) administered to fowls caused death, preceded by digestive disturbance and frequent evacuations. It is thought that if it were not that calumbin is present in calumba in only small amount (0.35 to 0.4 per cent.), it would prove an inconvenient constituent in the administration of the drug.—*Pharmaceutical Journal and Transactions*, April 3, 1886.

#### VIBURNUM PRUNIFOLIUM IN ABORTION AND MISCARRIAGE.

We have in these columns several times recently drawn attention to the use of black haw in the treatment of threatened abortion or miscarriage, and the statements which we have made have been again confirmed by the experience of Mr. J. H. WILSON (*Brit. Med. Journ.*, April 3, 1886). He states that his experience has more and more confirmed him as to its value in such cases, and while it is not always successful, in those cases in which it failed he has been able to account for its doing so. Either the medicine had not been commenced in time, or the ovum had been detached before the viburnum was taken, or there was some reason to suspect a syphilitic taint. In cases of habitual abortion, when he has an opportunity of commencing the viburnum shortly before the anticipated period, and continued it at intervals on the first appearance of threatening symptoms, these patients have invariably gone on to the full time, and done well, without being subjected to restrictions or debarred from active exercise.

In the next class of cases, where there may be reason to suspect even a partial separation of the ovum and a dilated external os, with severe pains and hemorrhage going on for hours, and the patient under the impression that she could not possibly go on to her full time, he has been astonished at its effect, more than three-fourths of these cases doing well.

The most sanguine advocate of viburnum could not expect it to do impossibilities, or to prevent abortion when there is "a gaping os, and a detached ovum presenting." One might as well expect to resuscitate a dead body by galvanism.

Mr. Wilson has never seen ill consequences follow the administration of the medicine, however often the dose has been repeated. In two cases only has it been followed by slight headache. One patient inquired if she had not been taking quinine. The symptoms had been relieved; therefore it was not continued. In the other case, the patient had taken,

4 grains of the extract every two hours. The only change was to extend the interval to four hours, and then gradually discontinue it.

Some patients have taken viburnum at intervals during the whole course of their pregnancy. It seems to act as a uterine tonic and sedative, and to relieve the woman of those harassing nervous forebodings which often lead to abortion. The patient, after taking only a few doses, has quite a changed expression. From a drawn, desponding look, her countenance becomes cheerful and happy.

On some of the plantations in America it is the popular belief a woman cannot abort if she be under the influence of black haw, although she may be taking medicine with a criminal intent. Mr. Wilson's experience would go far to confirm that opinion, for he has had patients in whom a succession of abortions have taken place, but, when under the influence of the medicine, they have been able to resist the severest tests,—frights, falls, strains, etc.,—and no ill effects have followed.

With regard to the mode of administering the drug: at first, the liquid extract was ordered, but the smell was so strong and objectionable that the whole house became impregnated; and in two cases, where the stomach could not retain it, the liquid was given as an enema.

He now orders the extract in pills of 4 grains, and finds it a convenient form; as usually made, they soon absorb moisture, and run into a mass, and therefore they should be gelatin-coated.

#### OBSTRUCTION OF THE BOWELS TREATED BY PARACENTESIS CÆCI.

At the meeting of the Medical Society of Victoria, held February 3, 1886, Dr. J. E. NEILD (*Australasian Med. Journ.*, February 15, 1886) read an account of a case of a man, aged 21, who sent for him on September 14 last, complaining of some pain over the cæcum and slight abdominal tenderness. There was no swelling, pulse and temperature were normal, but there had been constipation for three days. The condition of the bowels he connected with a supper of cray-fish and cucumbers. A dose of sulphate and carbonate of magnesia, with sulphuric ether, were given, and on the following day a mixture of castor oil and belladonna, with an external application of belladonna and glycerin over the region of the cæcum, which served considerably to diminish the tenderness. A week later the tenderness over the

cæcum had returned, and there was now some tympanitic swelling. The pulse went up to 115, and the temperature rose to 102°. As the bowels had been acting extremely irregularly, Dr. Neild concluded that the large bowel had temporarily lost its contractile power, and a mixture of strychnine, belladonna, and ginger was accordingly directed. The following day there had been no action of the bowels, and there was a doughy swelling extending from the cæcum half-way up the ascending colon, and it clearly contained both fæces and flatus. The pulse was 120 and the temperature 103°, and there was an expression of considerable anxiety in the patient's countenance.

Paracentesis of the cæcum was then performed with an ordinary hypodermic syringe, and the puncture gave exit to a large quantity of exceedingly offensive gas, and the swelling notably subsided. This treatment was quite successful. The abdominal tenderness continued for a few days, but the swelling gradually subsided. The enemata and strychnine and belladonna mixture were steadily persisted in, with occasional doses of castor oil. In a week the patient was well enough to go into the country, and he was seen there three weeks later by Dr. Neild entirely restored to health, with, however, an occasional tendency to constipation. It seems evident in this case that the peristaltic action of the bowels was arrested by the combined mechanical distention of fæces and flatus, and that the puncture of the bowel by relieving pressure averted constrictive inflammatory action.

#### THE TREATMENT OF BRONCHIECTASIS BY PARACENTESIS.

At the recent meeting of the Royal Medical and Chirurgical Society, Dr. THEODORE WILLIAMS and Mr. RICKMAN J. GODLEE (*Lancet*, March 27, 1886) communicated a conjoint paper on two cases of bronchiectasis treated by paracentesis, with remarks on the mode of operation. The first case was that of a gentleman, aged 67, who had suffered for two years from chronic bronchitis and emphysema, and six months later had dry pleurisy of the left lung. After the pleurisy the expectoration, before moderate, became profuse and somewhat fetid, the cough more and more harassing, and although Malvern and Bournemouth were visited and a great variety of antiseptic treatment was tried, he obtained no relief. On February 3 he was seen by Dr. Williams, who noted the exist-

ence of a bronchiectasis in the lower lobe of the left lung, the pleura of which was adherent. Tubular sounds were heard over two small areas, neither exceeding a half-crown in circumference, in the eighth interspace. At the request of Dr. Williams, a puncture was made by Mr. Godlee into the first area with an aspirating trocar and canula. Under antiseptic precautions the cavity was opened and a drainage-tube inserted. The result of the operation was that the cough nearly ceased, the expectoration, which was for a few days pneumonic, diminished from one pint a day to a few pellets, and became free from odor, and the patient gained flesh rapidly. At the end of six weeks the discharge ceased, the channel closed, and the wound healed up. Examination of the chest showed complete disappearance of tubular sound from the second area as well as from the first, and further shrinking of the chest-wall. The patient, at the close of nine months after the operation, remained free from cough and expectoration, and was able to walk four miles at a stretch.

The second case was that of a girl, aged 21, who, ever since an attack of typhoid fever, had had troublesome cough and copious expectoration, gradually increasing in quantity, and becoming more and more fetid. She had had hæmoptysis three times, on one occasion amounting to a pint. Examination of the chest showed several bronchiectases, two of which gave rise to very coarse râles over areas about the size of a half-crown in the sixth and seventh interspaces in the axilla; a third area was detected in the eighth space below the scapular angle. At first the patient improved under antiseptic treatment, the expectoration diminishing and becoming less fetid; but after a while these measures ceased to give relief, and an operation was decided on. On June 29, at Dr. Williams's request, Mr. Godlee passed a small exploratory trocar successively into each of the three marked spots, and, obtaining no result, inserted a large-sized aspirating trocar and canula into the seat of the first puncture in the sixth interspace. But an attempt to cut down on the cavity failed. A second operation was performed on July 16, and, after some exploratory punctures, Mr. Godlee, with antiseptic precautions, cut down on and laid bare the eighth rib, and excised about an inch of it in order to approach nearer to the bronchi before attempting to open them. The trocar and canula were then passed to a depth of five inches, and Mr. Godlee cut down along

the canula and inserted a drainage-tube. The wound gradually healed up, and the patient left the hospital at the beginning of September considerably improved, the cough slight, the sputum having diminished to about three ounces a day, and being only occasionally fetid. The presence of bronchiectases in other parts of the left lung, and possibly also in the right lung, precluded such complete success as was obtained in the first case.

A short account was then given of four other cases of bronchiectasis treated by tapping, in all of which the position of the cavities had been recognized and successfully punctured, but owing to the presence of other bronchial dilatations the success was only partial in these cases. The arguments in favor of the operation are: 1. The tendency to death by septicæmia in some form, unless proper drainage is effected. 2. The reduction in the amount of expectoration, this being due, not only to the removal of the matter, but to the disappearance of the effects of its irritation on the healthy bronchi. 3. The invulnerability of the lung-tissue, it being proved that punctures of this tissue give rise to little or no disturbance to the part or to the system generally. The difficulties of the operation are principally those of diagnosis of the exact positions of the bronchiectases: (1) from the presence of emphysema; (2) from the reverberatory character of their auscultatory sounds, which renders exact localization very difficult. Paracentesis of bronchiectases seems to be indicated under the following circumstances: 1. In cases where antiseptic treatment of all kinds has failed to correct the fetor of expectoration, and to allay the harassing nature of the cough, where death by septic pneumonia seems imminent. 2. Where the evidence goes to prove that the bronchiectases are confined to one lung, are situated in the lower lobe, and have overlying them an adherent pleura. It is not indicated where multiple bronchiectases exist in both lungs, where they are surrounded by emphysema, and where the pleura is non-adherent.

#### AN ALKALOID IN BETEL-NUT.

E. BOMBELON, according to the *London Medical Record* for April 15, 1886, announces that he has succeeded in isolating from the betel-nut a volatile alkaloid, resembling nicotine, to which he has given the name "arekane." He describes it as being left on the evaporation of an ethereal solution as a colorless oil, smelling like weak meat-broth and with a strongly alkaline reaction. It forms

varnish-like salts with tartaric, citric, hydriodic, and salicylic acids, the salicylate having a tobacco-like odor. The hydrochlorate gives with platinic chloride a yellow, with gold chloride a light yellow, with mercuric chloride a white, and with tannin a whitish precipitate. The taste of the free alkaloid as well as of the salts is said to be at first imperceptible, but afterwards becomes acrid. The alkaloid increases the secretion of saliva, slackens the pulse, and has a purgative action.

#### A CLINICAL STUDY ON THE VALUE OF ANTIPYRIN.

It can no longer be questioned that antipyrin is a truly valuable drug, though its sphere of practical usefulness will probably be limited to the therapeutics of children's diseases. Still, in a recent meeting of the Academy of Medicine of Paris, there arose some—and we admit not unweighty—voices against the admission of this drug into the Pharmacopœia. An outcome of that discussion of French physicians is an exhaustive treatise of DR. LAURE, of the Faculty of Lyons, who desires, by additional clinical proofs, to demonstrate that antipyrin is an acquisition to our remedial resources, and has an indisputable claim to the recognition of every practitioner. We embody in the following abstract of Laure's essay the most interesting and clinically important facts.

In charge of the children's station at the Charité of Lyons, Laure found ample opportunity to test the worth of antipyrin in the various infantile affections. In the *Revue Mensuelle des Maladies de L'Enfance*, of February, 1886, Laure details his experience with antipyrin on fifteen patients, viz. :

Typhoid fever.....	7
General military tuberculosis.....	2
Acute articular rheumatism.....	1
Grave scarlet fever, complicated with diphtheria	1
Pneumonia .....	1
Chronic pulmonary tuberculosis.....	3

In typhoid fever the immediate effects of the antipyrin medication were surprising. The febrile temperature could be lowered, to use Laure's expression, as it were, at will. The remedy was well borne by the stomach, and in the majority of instances the reduction of the hyperpyrexia coincided with an amelioration of the general state of the patient. Under the influence of the first doses Laure saw the appetite and intelligence return, and

several times also that peculiar and immediate improvement observed to follow the exhibition of a cold bath. The first five cases recovered without complication; in the sixth case the drug was ineffective on account of the underlying tubercular and meningeal element which the autopsy revealed later. Nevertheless, Laure declines to consider this complication with the cerebral affection a contraindication for the exhibition of antipyrin, as he has cured a child suffering from spasmodic hemiplegia and a suddenly contracted typhoid fever by the exclusive administration of antipyrin.

In a case of acute articular rheumatism the reduction of temperature, articular swelling, and pain was likewise satisfactory, though the ultimate results of the antipyrin treatment could not be recorded, as the patient escaped from the hospital.

In the case of pneumonia in which antipyrin was also administered, it was difficult to draw the line of demarcation between the results of medication and the natural progress of the affection.

Called as a consulting physician to a case of grave scarlet fever, complicated with nasal, auricular, and ocular diphtheria, and a high elevation of temperature, Laure had the satisfaction to note the successful issue of an almost hopeless case under the antipyretic influences of antipyrin.

In three cases of pulmonary phthisis, Laure could verify the statement of Huchard and Arduin, that antipyrin modifies the fever rapidly, and that the reduction of temperature is followed by a notable subjective improvement with augmentation of appetite and general functional energy.

In two cases of acute general tuberculosis the results of trials with antipyrin were, of course, not very encouraging. The antithermic action of antipyrin was certainly far less marked in these affections than in typhoid fever, though in one case a considerable reduction of temperature could be obtained.

Antipyrin in therapeutic doses appears to be exempt from all danger, provided, however, its employment is watched by the thermometer, and is not extended over too long a period. Nevertheless, the fact is not to be lost sight of that the drug can produce toxic symptoms subsequent either to its accumulation in the system or to an unusually slow elimination. Six grains administered in three successive subcutaneous injections suffice to kill a rabbit of medium size, as has been shown by the experiments of Bouchut and of

Laure. Among the symptoms of intolerance, the profuse sweats occasionally noted deserve a special mention. Still, they depend probably more often upon an idiosyncrasy in the patient than upon the dose and the method of the administration of the drug. Huchard holds that excessive doses create a special liability for the sweats, though in Laure's experience the person who took the smallest quantity of antipyrin showed the greatest sweating.

In four instances Laure observed a morbilliform eruption after the employment of antipyrin, which, however, produced no inconvenience to the patients, excepting in the case of a little girl, in whom an intense and painful pruritus necessitated the stoppage of the remedy.

The vomiting noted by other observers has strangely never been seen by Laure, who, on the contrary, claims that the drug was so well borne by the stomach that the patients insisted upon additional doses. Two of Laure's patients complained of heat in the throat and of a sensation of thirst, symptoms which can, however, with propriety be ascribed to the profuse sweating from which these patients suffered.

The antipyretic effect of antipyrin is, according to Laure's observation, by no means immaterial, for the drug can produce a reduction of temperature amounting to four to five degrees. In one of Laure's little patients the thermometer marked 106° F. at the first visit, and the next morning at the same hour it registered 98° F., the patient having absorbed 1 drachm of antipyrin in doses of  $7\frac{1}{2}$  grains, given every three hours. This reduction (amounting to 8° F. for twenty-four hours) is the maximum effect obtained in the experience of Laure.

The action of antipyrin is a pretty rapid one, and within an hour's time a considerable reduction of temperature can frequently be witnessed, though it is difficult to exactly fix a uniform time for its action. The first dose is usually the most effective one, as is also conceded by Huchard. In exceptional cases only we find its antipyretic influence ensuing at a later period.

Antipyrin appears to diminish diuresis and the elimination of urea, as has been especially pointed out by Jacobowitsch (*Jahrbuch für Kinderheilkunde*, Leipzig, 1885, vol. xxiii., No. 4), who, for this reason, absolutely condemns the use of the drug.

The diminution of the frequency of the pulse is wholly unproportionate to the fall of temperature. In one of Laure's patients the

pulse was 168 at the time the thermometer marked a fall of 3° F.

Laure cannot agree with Huchard on the point of the hæmostatic virtues of antipyrin, and says that even the ingestion of 1 drachm *pro die* was in two observed instances unable to stop a profuse bleeding from the nose. The alleged antifermentative properties of antipyrin have, in Laure's opinion, been exaggerated, though their existence is undeniable.

The question of contraindications of antipyrin demands a brief discussion. Arduin recently asserted that albuminuria was unfavorably influenced by antipyrin. Laure, on the other hand, could not verify this observation. The good results obtained with antipyrin in a case of cerebral tuberculosis appear to indicate a certain tolerance of the nervous system toward the drug. In fact, Laure claims that save profuse sweats, necessitating the suspension of the drug, there are no veritable contraindications for antipyrin. Remembering, however, the tendency of antipyrin to diminish diuresis and to check tissue-oxidation, it would not be prudent to prescribe the drug nor insist in its employment in subjects presenting a persistent scantiness of urinary secretion.

Laure regards the systematic administration of antipyrin in children's diseases as an eligible substitution of Brand's hydriatic measures, and prescribes the drug usually in doses of  $1\frac{1}{2}$  to 7 grains (according to the age of the child), every three hours, whenever the temperature exceeds 102° F. If the urine grows scanty, if profuse sweats, thirst, an eruption, or any other contraindication present itself, the remedy is to be suspended for two to three days.

The great solubility of antipyrin permits of its incorporation with almost every excipient. The syrups of orange-peel and of peppermint are especially suitable vehicles to disguise the taste of the drug.

Our author cites the following memorable declaration of Huchard concerning antipyrin: "Only when the fever constitutes not an element in a disease, but rather a complication of the same, the hour of antipyrin has come."

Laure concludes his valuable essay as follows: "Antipyrin has given us excellent results in typhoid fever, pneumonia, rheumatism, scarlet fever, and the hectic fever of tuberculosis, and proved its superiority over quinine quite manifestly. The rapidity of the thermic movements in the infantile patients renders

the antipyrin medication particularly eligible for the therapeutics of diseases of children."

#### THE TREATMENT OF GONORRHOEA BY ANTISEPTICS.

Gonorrhœa is by no means a trivial disease, and when due consideration is not paid to its frequent sequelæ it really becomes a serious complaint. However, like many other diseases, if competently treated in its early stage, its seriousness is much modified. We all know that gonorrhœa is caused by a specific virus which excites a specific inflammation of the urethra, together with certain specific inflammations of adjacent parts, and is often followed by a form of blood-poisoning known as gonorrhœal rheumatism. It is evident that if the initial lesion of the specific inflammation of the urethra is sufficiently combated the secondary lesions are hardly likely to occur. Since a micro-organism has been found in the discharge of all cases under twenty-one days' standing, which is by many believed to be a specific cause of the disease, it is evident that agents which will destroy this micro-organism will hold out the greatest hope of being cures for the disease itself. It is evident, therefore, that antiseptics are the drugs which are indicated under this view of the pathology of gonorrhœa, and the report of the treatment of four hundred and thirteen cases by Mr. R. H. FIRTH in the *Indian Medical Gazette*, March, 1886, which shows that corrosive sublimate furnished the best results, furnishes confirmatory evidence as to the truth of this view. Mr. Firth's results are appended in tabular form, as follows:

Treatment.	Number of cases treated.	Average number of days of disease.
Zinc sulphate, 5 grs. to $\mathfrak{z}$ i.....	40	24.3
Zinc chloride, $\frac{1}{2}$ gr. to $\mathfrak{z}$ i.....	44	27.3
Tannic acid, 5 grs. to $\mathfrak{z}$ i.....	10	29.7
Potassium permanganate, 1 gr. to $\mathfrak{z}$ i	30	19.9
Carbolic acid, 1 part to 40.....	29	23.6
Iodoform, 30 grs. to $\mathfrak{z}$ i.....	11	29
Silver nitrate, $\frac{1}{4}$ gr. to $\mathfrak{z}$ i.....	14	28.4
Corrosive sublimate, $\frac{1}{8}$ gr. to $\mathfrak{z}$ i....	51	20.1
Corrosive sublimate, warm, $\frac{1}{8}$ gr. to $\mathfrak{z}$ i.....	49	17.5
Chloral, 3 grs. to $\mathfrak{z}$ i.....	7	31.8
Boracic acid, 5 grs. to $\mathfrak{z}$ i.....	25	30.2
Quinine sulphate, 2 grs. to $\mathfrak{z}$ i.....	26	26.3
Sodium salicylate, 5 grs. to $\mathfrak{z}$ i.....	13	31
Lead acetate, 3 grs. to $\mathfrak{z}$ i.....	20	26.1
Bismuth and glycerin, 1 to 10 parts	21	25.5
Warm water.....	23	26.6
Total number of cases.....	413	

From the foregoing it will be observed that Mr. Firth has tried sixteen varieties of injection. Of these the corrosive sublimate, when exhibited warm, gave the best results, followed closely by the potassium permanganate, and then by the cold injections of corrosive sublimate. For the majority of these injections he has employed tragacanth mucilage as the basis, particularly for iodoform, bismuth, chloral, lead and borax, and he thinks the method of injecting the drug in a warm solution to be a point of the highest importance in the treatment of gonorrhœa.

The warm water is very soothing, and Mr. Firth thinks it enables the drug more readily to get at the mucous follicles of the urethra which are the chief seat of disease. He has always been very careful to see that patients understand how to inject properly. In the above cases no one of them received internally copiba or cubebs. The only medicines given were an initial purge, and the maintenance for ten days on a simple diet. One case under treatment at Manchester with carbolic acid, received marked benefit from hourly administration of 8 drops of antimonial wine. In no other case was medicine given, except it were purgative. Mr. Firth has been recently trying the effect of the ordinary zinc lotion, both sulphate and chloride, used warm. From the few observations he has made, he thinks the results will be nearly as good as those from warm corrosive sublimate. In conclusion he advises medical officers to try the warm corrosive injection, or at least for them to see that the injection they happen to prefer is used *warm*. By so doing he thinks they will cure their patients more effectively and more quickly, too, than heretofore. He advises the keeping gonorrhœal patients in bed for at least eight days; but that is a point which depends upon the degree of local inflammations.

In using the corrosive injections, it is as well after the acute stage is over to increase the strength of sublimate to  $\frac{1}{6}$  grain to the ounce of water. Such, Mr. Firth says, has been his practice.

#### CORROSIVE SUBLIMATE IN DIPHTHERIA.

DR. WERNER, medical officer to a circumscribed factory population of about two thousand near Narwa, in the Gulf of Finland, writes in the *St. Petersburger Medicinische Wochenschrift*, describing the satisfactory results he has obtained in diphtheria by treat-

ment with perchloride of mercury internally, combined with ichthyol inunctions. The disease is very frequent and fatal in the locality, he having attended during the last six years ninety cases, the average mortality of which was between sixty and seventy per cent., the majority succumbing from general weakness when the local affection was passing off or after it had quite disappeared. Last year the type was peculiarly severe. In July, August, and September eleven cases occurred, of which no less than nine proved fatal. From the end of September to the present time, however, during which period there have occurred seventeen cases, all of which were treated with perchloride of mercury, and many of which were very severe, there were only two fatal cases, neither of which was seen till a few hours before death.

The author's method of administration is as follows: For young children he dissolves a quarter of a grain of the perchloride in four ounces of water, for children of 6 or 7 half a grain in six ounces of water, and for adults three-quarters of a grain in eight ounces of water. This solution is given to the patients while they are awake every twenty or thirty minutes, in measured doses, so arranged that the quantities made up shall last from twenty to twenty-four hours,—i.e., about half a drachm in the case of young children, and a drachm in that of adults. When a good deal of sleep is obtained, larger doses are given at longer intervals. As a rule only milk is allowed as nourishment. If considerable pyrexia exists, an enema of from 10 to 30 grains of antipyrin, according to the age of the patient, is given, the rectum having been previously cleared out. Externally, ichthyol is diligently rubbed in over the swollen glands three or four times a day, the fingers being wetted with water when dry to permit of the rubbing being continued for some time. For the first two days of this treatment the local affection usually undergoes no improvement, but on the third day it begins to diminish and the general condition becomes better, the appetite increasing and the children regaining their wonted spirits. In no case did the author meet with the extreme debility which was frequent in cases treated by pilocarpine, even when the local affection was decreasing. As the patients approached convalescence the medicine was diminished, so that more than six bottles were never required. Complications never occurred, though three of the patients had previously had scarlatina.—*Lancet*, April 3, 1886.

#### ON THE OLD AND NEW METHODS OF TREATING CONGENITAL SYPHILIS.

PROF. MONTI reviews in the *Archiv für Kinderheilkunde* (vol. vi. No. 1) the advantages and inconveniences of the various therapeutic measures employed in the treatment of congenital syphilis. Our author makes the following divisions:

1. Frictions.
2. Calomel.
3. Corrosive sublimate.
4. Albuminate of mercury.
5. Peptonate of mercury.
6. Formamide of mercury.
7. Protoiodide of mercury.
8. Black oxide of mercury.
9. Tannate of mercury.
10. Iodine salts.

The friction-method is executed by (a) the blue ointment, (b) the oleate of mercury, (c) the mercurial plaster of Bayerdorf-Unna, (d) the mercurial soap.

All these preparations have the disadvantage of slightly irritating the delicate skin of children and of producing erythemata, eczematata, etc. Their action is rapid, and never causes salivation, unless the preparations are employed in too large a quantity or for too long a period. Mercury introduced into the system suddenly often determines an extreme anæmia. Cases of sudden death of children resulting from this medication are not rare. For these reasons Prof. Monti never employs mercurial frictions.

Calomel proves usually an efficient and rapid remedy for congenital syphilis, if persisted in for a sufficiently long time. To avoid the anæmia sometimes following upon the calomel treatment Monti uses only small doses of this drug, such as  $1\frac{1}{2}$  grains given in four doses *pro die*. After the disappearance of the symptoms of syphilis, it is indispensable to complete the treatment by the administration of the saccharo-iodide of iron in daily doses of  $1\frac{1}{2}$  to 4 grains.

The corrosive sublimate is best exhibited in a solution of  $\frac{1}{8}$  grain in 2 ounces of water, of which 2 to 3 teaspoonfuls are given daily. The sublimate baths influence the syphilitic lesions far more slowly, while the hypodermic injections of sublimate are not so well borne by children as by adults. The hypodermic employment of corrosive sublimate is only justifiable when the intestines are seriously implicated, or the syphilitic lesions imperil the life of the patient directly.

The action of the albuminate of mercury is rapid, but the great pain occasioned by the

hypodermic injections of this preparation contraindicates its employment. Besides, the preparation is very unstable, and consequently little available for general practice.

The peptonate of mercury is more stable than the preceding preparation, but it possesses otherwise no special advantages.

The subcutaneous injections of the formamide of mercury, even when employed in a feeble solution, are too painful to justify their application; besides, they often produce subcutaneous abscesses.

The protoiodide of mercury is an excellent preparation, especially when the osseous tissues are affected; unfortunately, the intestinal mucous membrane is easily irritated by this drug.

The black oxide of mercury is badly borne, and in most cases vomited up.

Monti has used the tannate of mercury in twelve cases with success. The syphilitic lesions disappeared rapidly under its use without any alteration of nutrition. Its dose is  $\frac{1}{3}$  to  $1\frac{1}{2}$  grains.

Iodide of potassium may either be used internally (3 to 6 dessertspoonfuls daily of a solution of 15 grains in 4 ounces of water) or in form of a bath. The saccharo-iodide of iron in form of a powder ( $1\frac{1}{2}$  to 4 grains daily) is also an eligible preparation. The internal administration of iodide of potassium provokes rapidly meagreness and iodism in children. The saccharate of iron, even if given for a long time, never produces wasting. Monti rarely prescribes for children the syrup of iodide of iron, as it often leads to a more or less violent intestinal catarrh.

#### THE TREATMENT OF WHOOPING-COUGH WITH CARBURETTED HYDROGEN.

All writers are pretty well agreed that uncomplicated whooping-cough of the sporadic kind is not a formidable complaint, and that its treatment may safely be left to the *vis medicatrix nature*; but, on the other hand, it very frequently is complicated, and sometimes seriously so, with convulsions, bronchitis, and pneumonia; while its most formidable sequels are emphysema and chronic affections of the bronchi. Various specifics have at different times been proposed, but all have in turn been abandoned. As is well known, improvement has frequently been obtained by the inhalation of the gases which are developed in the manufacture of illuminating gas, and therefore a course of visits to the gas-works has often served to produce

improvement in this disease; but as children frequently contract bronchitis and pneumonia from the exposure to cold from the overheating of the gas-works, this method of treatment can scarcely be looked upon as altogether satisfactory. DR. W. T. GREENE (*Med. Press*, April 7, 1886) believes that he has discovered a substitute for this method of treatment which will produce better results without the inconvenience of the former plan. He was led to this discovery from the fact that in one of his children, who was suffering from this disease in a severe form, after a day or two the symptoms gradually subsided and all trace of the whooping-cough disappeared in about ten days from the commencement of the attack. The explanation which he gives of this cure is that at the head of the child's cot there was a gas-pipe from which a slight escape of gas had been noticed for some time, but the workmen who had been sent for to repair the breach did not come, and so the gas continued in very small quantities to escape, and the little boy got rid of his whooping-cough in a marvellously short time. He repeated this mode of treatment in many other cases, and he claims always to have obtained the like gratifying result. His mode of administration is quite simple. A piece of ordinary gas-tubing is obtained of sufficient length to reach from one of the gas-burners to the floor, on which it may advantageously trail for a foot or two. The gas is then turned on sufficiently, just enough to make its odor perceptible, and the little patient allowed to stand over and inhale it for a few moments, as often as convenient. It will not make him cough, but, on the contrary, afford a grateful sense of relief, and after a few inhalations the more formidable symptoms of the disease will disappear, and will altogether cease to manifest themselves after a few days.

#### THE MICROBES OF INFECTIOUS OSTEO-MYELITIS.

PROFESSOR RATTONE in the *Archivio per le Scienze Mediche* (vol. ix.) publishes his latest observations on the germs of osteomyelitis, from which we abstract some points of general interest. The staphylococcus pyogenicus is a micrococcus which is found in pus, and cultivated on gelatin liquefies this substance. The streptococcus pyogenicus is another micrococcus, which is also found in the pus of an abscess; it is smaller than the former, and does not fluidify gelatin. According to numerous

observers, the staphylococcus is alone capable of producing infectious osteomyelitis.

Rattone observed in the pus derived from a deeply-seated abscess of a patient suffering from osteomyelitis the exclusive presence of a large number of streptococci. These two microbes not being identical, as can be clearly proven by special tests, especially by cultures in different substances, Rattone is led to regard the staphylococcus as the pathogenetic agent of osteomyelitis.

DR. CAVAGNIS, who reported the above facts in *Lo Sperimentale* (November, 1885), adds the following personal observation. He injected into the abdominal cavity of a rabbit a small quantity of blood, dissolved in a solution of chloride of sodium, drawn from the skin of a person affected with osteomyelitis of a grave, infectious form; the rabbit showed no pathological symptoms. The same observer injected into another rabbit a small quantity of pus taken from a tibial abscess of the same patient; the result was equally negative. Both rabbits were killed a fortnight later, but no abdominal lesions were ascertained.

The blood of the patient contained no micrococci, but the pus abstracted from him was crowded with micro-organisms. The question arises, whether the streptococcus, if found exclusively in pus, is not equally capable to propagate the osteomyelitic infection as the staphylococcus. Other experiments will be needed to definitely settle this point.

#### MYRTOL.

Myrtol has only been, hitherto, studied as a curiosity. DR. LINARIX, in his doctrinal thesis, *De l'Emploi du Myrtol*, gives a complete account of the properties of this substance. Myrtol is both an antiseptic and a disinfecting agent. By its presence, it prevents the decomposition of fermentative and putrescible organic substances; applied to the skin, it does not produce the slightest irritation, if the epithelium be intact. If there be a slight abrasion, a few drops produce a very trifling burning sensation, which quickly goes off. Myrtol stimulates the digestive faculties; all who use it find their appetite increased. In small doses, it acts as a sedative. It is eliminated by the lungs and kidneys, and has also a powerful balsamic action, but is more easily tolerated than most balsams. Its use is not followed by dyspepsia, nor by any of the other troubles attending the use of balsams in general. Dr. Linarix says that myrtol does not produce the same result at all periods of the

affections of the respiratory system; in sub-acute and chronic catarrhal affections, it should be administered when fever has subsided, then the sputa become less abundant, also less purulent. Six capsules daily, each containing fifteen centigrammes of myrtol, form a moderate dose, which should be taken before meals.—*Brit. Med. Journ.*, April 10, 1886.

#### ON BRONCHO-PNEUMONIA AND ITS MICROBES.

From the *Revue des Maladies de l'Enfance* of February, 1886, we abstract the following interesting views of DR. THAON, bearing on the microbic origin of broncho-pneumonia.

Our author leaves out of consideration the tubercular broncho-pneumonia, and simply discusses those forms which follow after an attack of diphtheria, measles, and whooping-cough.

The pneumonic exsudate is crowded by micro-organisms lodged in the pus-cells and the large epithelial cells of the lung-tissue. To obtain satisfactory results in the search for the microbes of pneumonia, the examination is to be made within twenty-four hours after death in the region of the most recent pulmonary lesion, and with the aid of a coloration-method which least alters these (very sensible) microbes.

Thaon found in the lung-tissue after the pneumonic process two varieties of microbes, described previously by Loeffery, in diphtheria, viz., zooglœa and bacilli; but, unlike the mentioned German observer, he does not regard the bacilli as the main agents of the pathological process, but holds the zooglœa as the more constant and pathogenetic element.

In the broncho-pneumonia following upon measles and whooping-cough, Thaon discovered microbes presenting themselves as diplococci in chains and also large bacilli.

We miss in the above note any mention of the so-called Friedländer's pneumococci; that is, the microbes first found and described by Dr. Friedländer in pneumonia.

#### THE USE OF SOME MODERN REMEDIES IN HEART-DISEASE.

DR. A. ERNEST SANSOM publishes in the *Lancet* (March 20, 27, and April 3) an elaborate paper on the use of caffeine and con-

vallaria majalis in cases of mitral disease. In nearly all cases of valvular heart-disease, in which there is a failure of compensation, the practitioner first resorts to digitalis, and in mitral incompetence digitalis may be given almost indefinitely, and patients often take it for years with obvious advantage. In mitral stenosis, however, there are many drawbacks to the use of digitalis, which are often manifest even in the early stages of failing compensation. With some patients the drug does not agree, and cannot be made to agree. It may induce faintness and sickness. In children sometimes vomiting is induced, and it cannot be persevered with. In other cases, though these symptoms be not manifested, the drug, instead of increasing the force and decreasing the rate of the pulse, actually increases the feebleness and the rapidity. In some the drug, instead of acting as a diuretic, diminishes the quantity of urine excreted, and in a few instances there may be insomnia, restlessness, and nervous disturbance. These signs of intolerance of digitalis in cases of mitral regurgitation are rare, but they are sufficient to make us cautious. It is a good rule, and one that Dr. Sansom always adopts, never to give an adult a larger dose than 5 minims of the tincture (or its equivalent in infusion or the powdered leaves) three times a day for a longer period than a week without constant observation. Then, if tolerance is assured, the patient may continue to take the drug, or the dose may be continuously increased. It is to be remembered that the effects of digitalis may last longer than the period of its administration.

It is in the later stages, however, that the failure of digitalis is most marked. Its power of increasing the force of the left ventricle seems to be gone. The right cavities continue to dilate, and dropsy may be manifestly increasing, and yet the agent in all combinations with ordinary diuretics fails to increase the flow of urine. Then we are compelled to rely on other agents, and the first of these which should be tried is caffeine. The general effects of caffeine, which the readers of the GAZETTE are familiar with, are to a certain extent identical with those of digitalis. It slows the heart, increases its force of contraction, produces diuresis, has no nauseous effects, and no cumulative action. This drug, therefore, does not require incessant watching, and may be employed in cases of heart-disease where the kidneys are affected. As to its mode of administration, Dr. Sansom generally employs the citrate, which is freely

soluble in water. He employs it in from 3-grain to 5-grain doses dissolved in ordinary liquor ammoniæ acetatis. The dose is generally administered three times in the day, but in some cases once only.

Instead of the citrate, the pure caffeine may be employed, dissolved in a solution of benzoate or salicylate of sodium. In these it dissolves freely, and thus a concentrated solution may be made for hypodermic injection. The following formula Dr. Sansom recommends for internal use: Pure caffeine and benzoate of sodium, 1 drachm; distilled water, 6 fluidounces. Half an ounce contains five grains of pure caffeine.

Dr. Sansom reports several cases of mitral regurgitation under his own care of great gravity, in which the resources of ordinary treatment had been exhausted, and in which caffeine citrate was administered. These cases showed in nearly all that the amount of urine passed during a considerable portion of the period when the drug was administered was in excess of the amount passed previously. They also showed that the influence of the drug as a diuretic may be prolonged beyond the time of its actual administration, and thus indicated that the dictum that caffeine is not cumulative in action must be reconsidered. His cases also showed that the pulse became more regular and stronger and reduced in frequency, and he concludes from these cases that caffeine in the treatment of cases of mitral regurgitation, in which failure of compensation has occurred, is a valuable agent,—that is, it is a powerful diuretic, and is therefore very valuable in dropsical cases: that it tends to increase the force of the heart, to calm the respiration, and reduce the temperature, but that it fails in some cases to be of benefit, even though it may manifest this diuretic force.

Dr. Sansom has also employed convallaria in similar cases, employing the extract made from the roots, leaves, flowers, and stem, the dose being 2 to 8 grains; the fluid extract, dose from 2 to 10 minims; and the tincture, dose from 5 to 30 minims. The convallaria appears to possess a cumulative tendency, and consequently only one dose of convallarin, a glucoside and the active principle of convallaria, should be administered each four hours. The experience of various observers in regard to the action of this drug is very contradictory, so much so that it has been suggested that the activity of the plant varies with the locality in which it is grown. If this be so, of course it can be obviated by

the employment of the active principle, convallarin. Dr. Sansom thinks that possibly part of the contradiction has been due to the fact that the conclusions of various observers have been based upon different forms of heart-disease and heart-disturbance, and he therefore has grouped a number of cases of mitral regurgitation in which convallaria was administered in doses of 5 grains of the extract, or 20 minims of the tincture, three times daily. In these cases of mitral regurgitation the influence of convallaria as a diuretic is far inferior to that of caffeine. The rates of the pulse and breathing were, however, reduced, and the force of the heart and tension of the pulse were increased, with an improvement in the regularity of rhythm. He thinks, therefore, that in convallaria we have a drug which may be occasionally used with advantage in cases of mitral regurgitation; that it should be continued for no longer than weekly periods without interruption; that in cases manifesting atrophy it should be accompanied with caffeine, but that for general and systematic administration in mitral regurgitation it will not, except at intervals, usefully supplant digitalis. So much for mitral regurgitation.

Dr. Sansom has employed the same drugs in a number of cases of mitral stenosis, in which, as is well known, digitalis is of much less advantage than in mitral regurgitation; for, in many cases, instead of promoting regularity of the heart's action, it notably increases irregularity. Considering first the use of convallaria majalis in such cases, he has found that in all cases of mitral stenosis convallaria exercised a pronounced diuretic effect, and he thinks it a fair conclusion that convallaria is an important diuretic in cases of mitral stenosis, comparable in its effects with caffeine in mitral regurgitation, and that its effects in this direction are more pronounced in the obstructive than in the regurgitant lesions. As regards the action on the pulse and respiration, he found that in all cases the pulse decreased in rate under the convallaria and increased in tension, while the breathing was improved under the drug in nearly all the cases.

Dr. Sansom's general conclusions are that caffeine is an agent of great value in the treatment of mitral regurgitation, especially in those in which there is much dropsy, and that convallaria, though manifesting no very variable influence in cases of mitral regurgitation, except as an occasional substitute for digitalis, is of considerable therapeutic importance in mitral stenosis.

#### THE THERAPEUTICS OF THE ACETATE OF COPPER.

DR. LUTON (*Journ. de Méd.*, February, 1886) has been experimenting with the external and internal application of the acetate of copper in scrofula and tuberculosis. For external application, he makes use of an ointment composed of thirty parts of lard and one of the neutral acetate of copper. This ointment has, in his hands, served him very well in the treatment of scrofulous ulcers, tubercles, lupus, fistulæ contracted from cold abscess, glandular abscesses, and opened white tumors. Its application is not painful, and patients bear it well. Under this influence the wound takes on a healthy appearance, and cicatrization rapidly follows. As regards the internal use of this remedy, he thinks that he has obtained favorable results from its employment in a certain number of phthisical patients. He has given to these patients acetate of copper in the dose of  $\frac{1}{100}$  of a grain each evening after the last meal, associated with  $\frac{1}{2}$  grain of extract of opium to enable it to be tolerated, and to produce some sleep. In some patients he was able to increase the dose up to  $\frac{3}{4}$  of a grain, without the addition of opium and without producing disturbance of the stomach.

#### RUSSIAN DIURETICS.

The Russians have great faith in diuretics, and therefore many drugs of this class are popular as household remedies. Some of these, such as foxglove, were in use among the peasants long before they were admitted into the category of even extra-pharmacopœial remedies prescribed by professional men. DR. S. A. POPOFF has recently made some researches on the action of certain household diuretics, communicating his results to the recent congress of Russian doctors. Cloud-berries (*Rubus chamæmorus*) are almost unknown in scientific medicine, though a paper on their diuretic quality was written in 1856 in German by Dr. Trinkovski, who recommended them in hydrocephalus. Dr. Popoff prepared infusions, decoctions, and tinctures, and also an acid which he believes to be the active principle, and found, by experiments on animals, that considerable increase in the urinary secretion was produced by the administration of any of the preparations by the mouth, under the skin, or into the veins. This occurred also when the spinal cord and the splanchnics were divided, and when the animal was under the influence of

curare. There was no alteration in the blood-pressure, and but slight palpitation of the heart. The only cases in which any slowing of the heart occurred were those in which a solution of the acid was introduced directly into the jugular vein. Nikanoroff's experiment of causing defibrinated blood to circulate through the kidney, first alone, and then containing the acid in solution, was tried, and the amount of blood flowing out of the renal veins determined, but no positive results were thus obtained. The author has no doubt that the cloud-berry acts by directly stimulating the renal tissue without acting on the heart or circulatory system. It has thus, he says, an effect similar to that of antihydropin (tincture of black-beetles), which is well known in Russia, and prescribed frequently, but this latter has the more powerful action of the two.—*Lancet*, March 6, 1886.

#### EMPLOYMENT OF TIN IN TREATMENT.

The metal tin, though long known, for it was used in the manufacture of bronze, has not entered to any large extent into the pharmacopœias of this, or, so far as we know, into those of any other country. The word "bedil," which is translated "tin" in the Old Testament, "stannum" in Latin, and *χασίτερος* in Greek, is not certainly to be identified with that metal, and, according to Roscoe and Schorlemmer, it is doubtful whether the metal which the Phœnicians are said to have brought from the Cassiterides, whose exact locality was unknown to Herodotus, was really tin. It is certain, however, that the metal was known to Pliny, that after Cæsar's conquest it was obtained from the Cornish mines, and that Diodorus Siculus describes its conveyance to a small island named Iktis, the topographical features of which, as described by him, correspond accurately with those of St. Michael's Mount in Cornwall.

Most authors hold with Orfila that tin has no toxic properties, since it is but slightly attacked by a solution of hydrochloric acid of the strength in which this acid exists in the gastric juice, and hence can only be absorbed in small quantity. According to DR. PATENKO, of St. Petersburg, who has lately devoted himself to the study of the toxic effects of tin, it has been administered in England in the metallic state, in accordance with instructions given by Dr. Alston, who published some lectures on materia medica in 1770. These instructions are that the patient should take a

purgative of senna and manna on a Thursday before a new moon; on the following day an ounce of metallic tin is administered in four ounces of syrup; on Saturday half an ounce more tin is administered in two ounces of syrup, and the same quantity on Sunday; on Monday another purge of senna and manna is given. The success of the remedy, if it ever prove successful, has been attributed by some to the presence of arsenic, which is always present in ordinary tin; whilst MM. Cahours and Solyet consider that an active compound, distannethyl, may be formed in the intestine and become the active agent. Other experiments have shown that the injection of the protochloride of tin into the jugular vein of a dog, in doses not exceeding 5 grains dissolved in ten parts of distilled water, causes death with tetanic symptoms in from one to fifteen minutes, or, if ingested, vomiting, debility, and death. On post-mortem examination the gastric mucous membrane, and even that of the duodenum and jejunum, exhibited thickening and ulceration.

M. Patenko's researches, pursued in Professor Vulpian's laboratory, were confined to the metal itself and to the bichloride. He commenced by giving to two dogs 3 grains of chemically pure tin in powder once daily with the food, and continued its administration for six weeks. No indications of any injurious effects were observed; on the contrary, the animals preserved excellent appetites, and were lively and gained in weight. It was incidentally shown at the necropsy of one of the dogs that the metal had not caused the expulsion of numerous ascarides with which it was infested, nor of a *tænia serrata*. The urine contained no tin, nor was any found in the brain, liver, spleen, or kidneys. The powder was present in the fæces. It did not, therefore, appear to be absorbed.

The administration of the bichloride of tin gave different results. The animals experimented upon were frogs, guinea-pigs, and dogs, and it was injected subcutaneously, thrown into the peritoneal cavity, and introduced into the stomach. When subcutaneously injected it caused, in small and diluted doses, local anæsthesia, which augmented and extended when larger quantities were employed. Strong solutions caused gangrene, which penetrated deeply, destroying not only the whole thickness of the skin, but subjacent organs, such as the liver and stomach. Injections made into the peritoneal cavity exhibited its caustic properties, but no special peculiarities. Injected into the veins, in doses not

exceeding three-fourths of a grain, death rapidly followed, but the immediate cause of death was not apparent, and has not been ascertained, though it was probably due to the action of the agent on the central nervous system and upon the muscles. The action on the stomach was not marked; even when given in rather large quantities for some time with the food it only caused indigestion. On the whole, therefore, the observations of Dr. Patenko confirm those of previous experimenters, and show that the metal has no poisonous action, but that the bichloride acts essentially on the central nervous system and the muscles.

#### ANTIPIRYN IN OPHTHALMIC PRACTICE.

Some observations by Khomyarkoff and L'voff, tending to show the superiority of antipyrin over salicylate of sodium in articular rheumatism and migraine, having induced a Russian ophthalmic surgeon, DR. T. N. KATSAUROFF, to try it in cases of ciliary neuralgia and headache accompanying various eye-diseases, he has published the results of this method of treatment in the *Vratch*. The patients comprised seventeen males and ten females, their ages varying from seventeen to seventy-five. Apart from the eye-affection, all but three were free from disease. The antipyrin was always given in doses of a gramme (15 grains), and in every case appeared to be of distinct benefit in relieving the pain, a single dose being sufficient in fourteen cases, while in thirteen cases this had to be repeated, in two of them only (optic neuritis and scleritis) a third dose being found requisite. The author mentions that in nine cases where operations for cataract had been performed, and the enforced subsequent dorsal position proved so irksome as to induce headache, the antipyrin seemed particularly valuable, though two of them were complicated by iritis. The action of the drug in these cases was rapid, an improvement generally taking place in half an hour, and the pain being completely relieved in an hour. More or less satisfactory results were obtained in ciliary and cephalic pain accompanying different forms of keratitis, of which there were four cases; in corneal ulcers, of which there were three cases; and in glaucoma, of which there were ten cases. The drug seemed, however, to have less effect on a case of double neuritis, on two of atrophy of the optic nerve, and on one of scleritis. As observed by

Khomyarkoff and L'voff, antipyrin proved very valuable in Dr. Katsauroff's hands in migraine, his case being of traumatic origin, a foreign body having penetrated the soft structures of the orbit. Previously to using antipyrin as described, Dr. Katsauroff had been in the habit of employing salicylate of sodium in cases of headache accompanying eye-diseases, but he found that it was often necessary to give it in such large doses as to cause singing in the ears, whereas no unpleasant effects were produced by antipyrin in any of his cases.—*Lancet*, April 10, 1886.

#### DOUBLE PNEUMONIA TREATED BY PILOCARPINE.

DR. H. MOLIÈRE and his assistant M. FOCHIER publish in the *Journ. de Médecine*, February, 1886, a note relative to the good effects of pilocarpine in a case of double pneumonia. The case was that of a man greatly weakened by dysentery and albuminuria, who was attacked by double pneumonia, under which disease his intestinal troubles became greatly increased. The state of the patient appeared desperate, when an injection of  $\frac{1}{100}$  of a grain of pilocarpine was given. As the result of this, the number of respirations fell from 48 to 24, and the dyspnoea was greatly relieved. Four hours after another injection was given, which was again repeated on the next morning. After each of these profuse sweating and salivation came on, while at the same time there was the greatest relief in the dyspnoea. The patient was carried on to defervescence, and was soon cured. Molière adds, that he employed pilocarpine in this case on account of the analogy which he had observed in other instances. Thus, in an old man, who was attacked by uræmia, in its form of dyspnoea and delirium, and who appeared on the point of death, an injection of  $\frac{1}{100}$  of a grain of pilocarpine caused almost immediately a disappearance of all the symptoms, which, however, again returned in the evening to be again relieved by a second injection. So, also, in a young woman in the comatose form of uræmia, and in whom the renal lesion was secondary to an organic affection of the heart, the pilocarpine immediately arrested the coma, and so permitted the possibility of acting directly on the heart and regulation of the circulation. But in this latter case it is certain that, in consequence of the diseased condition of the renal epithelium and the pulmonary congestion, the

purification of the blood was almost entirely prevented, so that uræmia was combined to a certain extent with asphyxia; and although the profuse sweating and salivation produced by the pilocarpine, by reducing the congestion of the lungs, permitted the removal of the asphyxia, and also to a certain extent the uræmia, the sweating could only temporarily relieve this latter condition but could not cure it.

#### THE PHYSIOLOGICAL ACTION OF ANTI-PYRIN AND KAIRIN.

In the *Meditzinskoie Obozrenie*, Fasc. xii., 1885, p. 1203, DR. S. J. PAVLINOFF (*London Med. Record*, March 15, 1886), of Moscow, describes the results of his experiments which have been carried out, under Professor L. Z. Morokhovetz's guidance, in order to compare chemical and physiological properties of antipyrin with those of kairin.

**Chemical Properties.**—The preparation of antipyrin was obtained from Ferrein, and represented an amorphous yellowish powder of pretty strong bitter taste, with aromatic flavor. It was soluble in water and ether; the solutions were neutral. Kairin belongs to light oxidizable substances; its solutions, kept in contact with the air, within twelve hours become of a ruby color, and in a few days rich dark cherry-red. On the other hand, solutions of antipyrin remain unchanged (that is, either colorless or yellowish) for a month, or even longer. Being treated by nitric acid, kairin solutions turn to dark cherry-red, and, on being subsequently diluted, they gradually become yellow, the latter coloration occurring still even when only 0.001 per cent. of the drug is present. Antipyrin gives no reaction with the acid. But both kairin and antipyrin solutions assume a claret-red color on being treated by perchloride of iron ( $\text{Fe}_2\text{Cl}_6$ ).

**Physiological Action.**—A. *Blood.*—As Morokhovetz showed, when mixed with an equal volume of a 0.001 per cent. solution of kairin, the blood assumes a claret-red color, and gives the methæmoglobin bands on the spectroscopic examination. The red blood-corpuscles take a cup-like form and brownish color. But antipyrin remains entirely inactive, even when a one per cent. solution is employed. The same difference between the two substances is observed, also, when intravenous injections of their solutions in dogs are undertaken. B. *Blood-pressure.*—Antipyrin induces an increase of the arterial tension, while the latter is rapidly and very considerably lowered by kairin

(after a fleeting initial rise). C. *Pulse.*—Under antipyrin, the pulse becomes somewhat retarded, but its rhythm remains regular; while under kairin it quickens and assumes a filiform character. Some experiments seem to point out that kairin affects the cardiac muscle, the cardiac nerve-apparatus remaining intact. On the contrary, antipyrin appears to act on the latter, and to leave intact the former. D. *Respiration.*—Antipyrin produces a very considerable quickening of the respiration, the type of which, however, remains uniform all through. On the other hand, kairin brings about interrupted or irregular breathing. Therefore, as far as circulation and respiration are concerned, kairin and antipyrin are endowed with diametrically opposite actions. E. *Salivary Glands.*—Both of the drugs augment the secretion of saliva; antipyrin may be detected after a while in the latter, though in small quantities. F. *Pancreas.*—Neither antipyrin nor kairin has any influence on the secretion of pancreatic juice. G. *Liver.*—Kairin increases the secretion of bile, the color of which gradually turns to black, while antipyrin remains entirely inactive. H. *Kidneys.*—Neither of the drugs manifests any action on the quantity of urine. But the first portions of urine voided after the introduction of antipyrin contain a considerable quantity of the drug. Therefore, antipyrin is eliminated from the system through the kidneys and salivary glands. I. *Motor Nerves.*—Dr. Pavlinoff confirms the statement of Morokhovetz that kairin, like curare, affects the intramuscular endings of the motor nerves (in frogs); the drug acts antagonistically to strychnine (as Professor F. P. Sheremetevsky supposed). Nothing of the kind is noted as regards antipyrin. J. *Reflex Action.*—Antipyrin increases the reflex action (as Professor Demme, of Berne, first proved). K. *Temperature.*—Antipyrin depresses the normal temperature, but not at any uniform rate, the latter varying from  $0.5^\circ$  to  $2^\circ$  C. and more; generally speaking, the depression is the more marked, the shorter are the intervals between the doses administered. Under kairin, the temperature sinks in consequence of the drug absorbing oxygen of the blood; hence the use of kairin in cases of pneumonia, chronic pulmonary disease, anæmia, cardiac disease, etc., is fraught with obvious and immediate danger. In all such cases, antipyrin may be safely and effectively administered, the drug being indifferent in its chemical behavior towards the blood, and, if anything, strengthening the cardiac action.

## ON PTYCHOTIS AJOVAN.

From *Le Progrès* (Geneva, February 20, 1886) we abstract the following note about ptychotis, or carum ajovan, an Indian plant possessing medicinal virtues which has hitherto been but little known in this country.

This plant, belonging to the umbelliferae and extensively cultivated in India, seems to have been first brought to the notice of the English profession by Dr. Percival, but soon fell into an undisturbed oblivion. The ajova seeds are, according to the testimony of Dr. G. WARING, the most active of all carminative umbelliferous species, and combine the stimulating action of capsicum or sinapis with the bitter properties of chirata and the anti-spasmodic ones of asafœtida. The Indian pharmacopœia contains an ethereal oil and a distilled water, gained from the ajava-seeds. The seeds are at present largely used in the preparation of thymol, and it is possible that this drug, obtained from the ajava-base and combining antiseptic with powerfully-stimulating properties, may be of service in the treatment of cholera. As the seeds suppress the desire for alcoholic drinks, they may also form a valuable adjuvant to the therapeutics of dipsomania.

From this same journal we abstract the following remarks concerning three other Indian drugs as yet not employed by American practitioners :

(1) *Plantago ispaghula*.—One part of the seeds of this plant mixed with twenty parts of water makes a thick, tasteless jelly, and therefore is far preferable to the quince-seeds. Though of service as a demulcent in catarrhs and kidney-troubles, the principal value of these seeds lies in their efficacy against diarrhœa. The European residents of India prefer the ispaghula-seeds to any other remedy in chronic diarrhœa. The dose for an adult is 2 drachms of the seeds, taken in an uncommuted form, with  $\frac{1}{2}$  drachm of sugar. The seeds passing through the intestinal track take up a large amount of water and swell up, and having passed the lower portion of the bowels, they give up the large quantity of consistent mucus they previously absorbed.

(2) *Scopolia lurida*, a mydriatic rivalling and perhaps excelling in energy belladonna. The tincture prepared from the leaves of this plant (1 part of the leaves to 8 parts of alcohol) given to various patients produced an extreme mydriasis, and in two cases even blindness, which only disappeared after the suspension of the drug. The maximal dose is 20 drops in twenty-four hours.

(3) *Jatropha curcas*.—This plant contains a milky juice possessing considerable hæmostatic power. Through the local application of the freshly-prepared juice the stoppage of hemorrhages has been obtained which did not yield to the action of alum, chloride of iron, and turpentine. It is claimed that this juice causes no pain, and has no caustic action, but that it simply coagulates the blood and covers the bleeding part with a tenacious fluid. Applied subcutaneously the juice is said also to cure aneurisms.

---

BELLADONNA IN THE TREATMENT OF  
NOCTURNAL INCONTINENCE OF  
URINE.

The frequency and difficulty experienced in the treatment of nocturnal incontinence of urine in children, and occasionally in adults, renders any additional light on the therapeutics of this troublesome affection particularly acceptable. A point which appears new to us is brought out in a report of a case by MR. H. A. HUSBAND (*Can. Lancet*, May, 1886), and seems to fall under this category.

The case was that of a boy, aged 19 years, the eldest of four sons, all of whom had been troubled with the same complaint since birth. The patient had at various times been treated with tincture of belladonna, but with no apparent benefit. It was found that the boy suffered from chronic constipation, which was relieved by a pill of extract of rhubarb and nux vomica, given night and morning.

The lower bowel was washed out every night with an enema of warm soap and water, and then a suppository containing one grain of belladonna placed in the rectum. The object of the enema was to clear out any hardened fæces or thread-worms, which, by their presence, might by their irritation produce the incontinence. This treatment was rigidly continued for three months with some slight benefit, a week or two passing without a return of the complaint. The amount of belladonna was now increased to a grain and a half. And then a new symptom made its appearance. The nocturnal incontinence ceased, but the patient during the day became troubled with a constant desire to pass water, the annoyance being so great that he had to micturate every five minutes. The suppository was then ordered to be used night and morning, with the entire discontinuance of the nocturnal and diurnal trouble. During the last three months the pupils became permanently dilated, but there was no

irritation of the skin, and only occasionally slight dryness of the throat. In six months a complaint which had lasted nineteen years was completely cured, and the patient was enabled to proceed to the continent on his business, taking with him a mixture containing nitro-muriatic acid, strychnine, and gentian. The conclusions drawn from the above case are these, that of all preparations of belladonna the extract is the best, that the success in treatment, to a great extent, depends on the clearing of the rectum of its contents, and the application of the belladonna as near the bladder as possible, and that partial success at first is no reason to discontinue the treatment in despair.

#### ON MORRHUOL, THE ACTIVE PRINCIPLE OF COD-LIVER OIL.

In spite of the numerous existing preparations and emulcents intended to disguise the repulsive taste of cod-liver oil, the objection of many patients to the oil in any shape or form cannot be overcome. In view of this fact, well known to every practitioner, the question of isolating the active principle of cod-liver oil becomes one of universal interest. M. CHAPOTEAU has the credit, as far as our knowledge goes, of having first enriched the pharmacal resources of the profession with morrhuol, the isolated active principle of cod-liver oil. The *Progrès* of February 20, 1886, contains the details of the isolating process, as first published by Dr. Joseph Lafage in *Le Bull. de Thé. and le Bull. Com.* According to the mentioned source, morrhuol is a sharp, bitter, and very aromatic substance, crystallizing partly at an ordinary temperature. It contains phosphorus, iodine, and bromine in notable quantities, about ten to twelve times as much as is contained in the primitive oil. These different bodies are so intimately united that their separation resists all efforts. The active principle of cod-liver oil is thus seen to be a rather complex body. The cod-liver oil itself loses its medicinal properties wholly after the separation of morrhuol and simply acts as a fatty substance. On account of the pungency of morrhuol it is preferable to administer it only in capsules, 3 to 5 drops, which correspond to about 1 drachm of cod-liver oil. Children 6 to 8 years of age may receive two capsules; children 8 to 12 years of age four capsules, and adults eight capsules *pro die*. Even a prolonged employment of morrhuol occasions no digestive troubles,

but appears, on the contrary, to improve the appetite, and to give more rapid results than cod-liver oil.

Lafage obtained very gratifying results with morrhuol in tuberculosis at its first stage, in scrofulosis and rachitis, and in chronic bronchitis. The above recommendation of morrhuol ought to induce us to give this preparation a trial.

#### THE TREATMENT OF RETENTION OF URINE WITH THE CAPILLARY CATHETER.

The skilful use of the catheter in a large proportion of cases of retention of urine associated with organic stricture is followed by immediate relief, but the operation is often prolonged, and always very painful, unless performed under the influence of an anæsthetic. Sometimes the urethra is lacerated, and, when this accident occurs, irritation or fever are excited, which are soon followed by increased contraction of the strictured part of the canal. Cases of retention in which it is found impossible to introduce into the bladder any kind of instrument are of rare occurrence at the present day; but when such cases are met with, provided the patient's condition demands immediate relief, the bladder should be aspirated at once above the pubes.

DR. J. WARD COZZENS suggests in the *Med. Press*, March 31, 1886, a trial of the capillary catheter, which he has now used successfully in many cases of retention with great satisfaction. The operation is practically painless, and requires no anæsthetic, while the flexible capillary catheter, even if it fails to do good, can really do no harm. The form which he uses is a compound instrument, consisting of a filiform bougie and a fine catheter, very carefully prepared with woven web and gum elastic, and possessing great flexibility and toughness, together with a smooth and highly-polished surface. His method is to first inject the urethra with warm oil, and gently pass the catheter down to the stricture. As soon as its progress is stopped, it must be rotated between the thumb and finger, then withdrawn two or three inches, and twisted down again upon the obstruction. During the repetition of these procedures the little instrument often readily passes into the bladder. After the operation is over the instrument may be retained for a few days, or it can be removed and introduced in a day or two, and employed as a guide for a tubulated catheter.

*THE ACTION OF GRINDELIA ROBUSTA  
ON THE HEART AND CIRCULATION.*

Following the suggestion of Professor S. P. Botkin, DR. V. P. DOBROKLONSKY, of St. Petersburg, has undertaken (*London Med. Record*, March 15, 1886; *Ejenedelnaiia Klinitcheskaiia Gazeta*, No. 34, 1884, p. 535) a series of experiments on frogs, in order to examine the action of fluid extract of *grindelia robusta* on the heart and circulation. The main results may be summarized as follows:

1. In small pharmacological doses (0.1 to 0.2 cubic centimetre) (1½ to 3 gtt.) the drug causes a slight and fleeting quickening of the heart and an increase of the arterial tension, lasting for several tens of minutes. 2. In large pharmacological doses (0.4 to 0.6 cubic centimetre) it decreases both the frequency of the heart and the arterial tension, the heart ultimately stopping in diastole. 3. In moderate pharmacological doses (0.2 to 0.4 cubic centimetre) the drug, in the beginning, slightly quickens the cardiac contractions and elevates the blood-pressure, but subsequently gradually, but considerably, slows the heart, the arterial tension falling somewhat later. 4. In toxic doses (0.6 cubic centimetre and upwards) the drug swiftly stops the heart in diastole. 5. A *preceding* division of the spinal cord, or of the vagi and sympathetic, or of both of the cord and nerves named, or a preceding subcutaneous injection of sulphate of atropine, does not change the phenomena as stated above; but when made *after* the subcutaneous injection of *grindelia*, they diminish the number of cardiac contractions from seven to six a minute. 6. A series of experiments with an isolated heart gave essentially the same results as the experiments with the whole animal. 7. Small doses of the extract cause constriction of the arteries; moderate doses first contract and then dilate the vessels; and large doses dilate the latter from the very beginning. 8. Moderate doses rapidly bring about a decrease of excitability of nerves and muscles; the excitability of nerves sinks somewhat sooner, and from comparatively lesser doses than that of muscles. DR. Dobroklonsky at present is studying the action of *grindelia* on warm-blooded animals; he mentions, however, in his present note that the results obtained up to the date have been, in their essential features, identical with those for cold blooded.

In the *Russkaia Meditz.*, No. 1, 1886, p. 11, DR. L. GRINEVITZKY highly praises the services obtained from the administration of fluid extract of *grindelia robusta*, in daily doses of

2 or 3 drachms, in inveterate chronic bronchial catarrh. Asthmatic attacks are as rapidly and as strikingly relieved. Distressing cough soon disappears, nearly altogether, and expectoration becomes easy. The drug, however, entirely fails to relieve any respiratory disturbances accompanying other pulmonary diseases, as well as those caused by cardiac and nervous diseases.

*A SEMI-OFFICIAL DESCRIPTION OF SOME  
NEW REMEDIES.*

The Pharmaceutical Commission of the German Pharmaceutical Association having received a number of new remedies for examination, has published the results in the following paragraphs (*Pharm. Journ. and Trans.*, April 17, 1886):

AMMONIUM SULPHO-ICHTHYOLICUM.

*Ichthyl-Sulphonate of Ammonium.*

A red-brown syrupy liquid with igneous bituminous odor and taste, puffing up considerably and carbonizing when heated, and upon continued incineration volatilizing without residue. Water dissolves it to form a clear red-brown liquid of faintly acid reaction, and the same is the case of a mixture of equal volumes of alcohol and ether. Pure alcohol or ether dissolves it only partially; petroleum benzine only takes up a small quantity. Upon the addition of hydrochloric acid to the aqueous solution a dark resinous mass is precipitated, which, when separated, is soluble in ether and in water, but is again thrown out from the latter solution by hydrochloric acid or sodium chloride. Treated with potassium solution, the preparation develops an odor of ammonia, and the mixture dried and burnt yields a hepatic coal, which, with hydrochloric acid, gives off sulphuretted hydrogen.

The ichthyolate of ammonium loses upon drying in a water-bath at least half its weight.

ARBUTINUM.

*Arbutin.*

Slender, white shining crystalline needles, without smell, with a gradually developed, but persistent, bitter taste, melting at 167° to 168° C., and burning at a higher temperature without residue. It forms neutral solutions with 8 parts of cold water, 1 part of boiling water, and 16 parts of alcohol; in ether it is scarcely soluble. Upon heating 1 part of arbutin with 8 parts of peroxide of manganese, 2 parts of

sulphuric acid, and 1 part of water it gives off the penetrating odor of quinone. The watery solution is rendered blue by a small quantity of solution of perchloride of iron and green by a larger quantity. No precipitate is produced by either acids or alkalies. It blackens ammoniacal silver nitrate solution first after boiling with dilute sulphuric acid, and throws down cuprous oxide from alkaline copper solution upon heating. It dissolves in sulphuric acid colorless, turning red after a short time; a trace of nitric acid turns this solution yellow-brown.

An aqueous solution (1 in 20) is not changed by sulphuretted hydrogen.

NATRIUM SULPHO-ICHTHYOLICUM. ICH-  
THYOLUM.

*Ichthysulphonate of Sodium. Ichthyl.*

A brown-black tar-like mass with a bituminous odor, puffing up when heated, and carbonizing to an alkaline hepatic coal, which colors the flame intensely yellow, and, after continued incineration, leaves an ash, an aqueous solution of which with excess of nitric acid is at once colored strongly blue by barium nitrate. Water dissolves the preparation to form a somewhat turbid, dark brown, almost neutral, liquid, with a green fluorescence. A mixture of equal parts of alcohol and ether dissolves it with a clear deep brown color, as also does benzol, but pure alcohol or pure ether dissolves it only partially, and petroleum benzine scarcely at all. The aqueous solution treated with hydrochloric acid in excess throws out a dark resinous mass, which, after separation, is soluble in ether and in water, but is again separated from the latter by hydrochloric acid or sodium chloride. No ammonia is evolved from the aqueous solution upon warming it with soda solution.

PELLETIERINUM TANNICUM.

*Pelletierine Tannate. Punicine Tannate.*

A yellowish amorphous powder, without smell, with an astringent taste and faintly acid reaction; soluble in about 700 parts of water, 80 parts of alcohol, and freely in dilute acids upon warming. The aqueous solution is precipitated blue-black by perchloride of iron. If a hydrochloric acid solution be shaken with excess of soda solution and ether, the ether separated leaves after evaporating spontaneously slightly yellowish oil-like drops, having a peculiar odor and strongly alkaline reaction, and which form fumes when brought near to hydrochloric acid.

PYRIDINUM.

*Pyridine.*

A clear, colorless, volatile liquid, with an igneous odor and burning taste, and, in aqueous solution, an excessively alkaline reaction; boiling at 116° to 118° C.; miscible clear with water, alcohol, ether, benzene, and fixed oils. Specific gravity 0.980. Pyridine gives rise to precipitates in solutions of most metals, but not in those of lead acetate and magnesium sulphate. Copper sulphate solution is colored deep blue by excess of pyridine. Hydrochloric acid solution of pyridine gives with solution of iodine a brown, with bromine water an orange-yellow, and with platinum chloride a yellow crystalline precipitate.

Pyridine should not be altered by light. An aqueous solution (1 in 10) is not reddened by phenolphthalein; 5 c.c., with two drops of volumetric potassium permanganate solution added, should preserve the red color at least an hour.

0.79 gramme (0.8 c.c.) of pyridine is saturated by 10 c.c. of normal hydrochloric acid.

THALLINUM SULPHURICUM.

*Thallin Sulphate.*

A yellowish-white crystalline powder, with an odor resembling that of coumarin, and an acid saline, but at the same time bitterish aromatic taste, melting upon being heated, and carbonizing to a heavy but completely combustible coal. It is soluble in 7 parts of cold water, ½ part of boiling water, more difficultly in alcohol, and almost insoluble in ether. The aqueous solution has an acid reaction, turns brown gradually under the influence of light, and gives a brown precipitate with solution of iodine, and a white one with tannic acid; barium nitrate produces a white precipitate insoluble in hydrochloric acid, and caustic alkalies give rise to a white precipitate that disappears upon shaking with ether. A dilute aqueous solution (1 in 100) is colored by perchloride of iron deep green, passing, after some hours, to deep red; fuming nitric acid colors a dilute aqueous solution reddish. Sulphuric acid dissolves thallin sulphate colorless, but upon the addition of nitric acid it becomes deep red, and immediately afterwards yellow-red.

Thallin sulphate should be kept sheltered from light.

THALLINUM TARTARICUM.

*Thallin Tartrate.*

A yellowish-white crystalline powder, with the smell and taste of thallin sulphate, solu-

ble in ten parts of water, less freely in alcohol, and scarcely soluble in ether. When heated, it melts and carbonizes. The aqueous solution shows the same reactions as that of thallin sulphate, except that it remains unaltered on addition of barium nitrate, and upon the addition of potassium acetate it separates a crystalline precipitate, forming flocks with lime-water.

To be kept sheltered from light.

#### URETHANUM.

##### *Urethan.*

Colorless prismatic crystals, odorless, and having a peculiar cooling taste, melting at  $48^{\circ}$  to  $50^{\circ}$  C., boiling at about  $170^{\circ}$  C., and subliming undecomposed, or, if ignited, burning without residue. Urethan readily forms clear neutral solutions in water, alcohol, ether, and chloroform. In sulphuric acid it dissolves without color; upon heating the solution foams and gives off a colorless and odorless gas. Heated with potassium solution ammonia is evolved.

An aqueous solution (1 in 10) does not become turbid on the addition of silver nitrate; 2 volumes mixed with 1 volume of sulphuric acid, and 2 volumes of ferrous sulphate solution run in on the top, should not form a brown intermediary zone.

#### A NEW OPERATION FOR CATARACT.

SURGEON-MAJOR GEOFFREY C. HALL describes in the *Indian Med. Journal*, March, 1886, a new operation for the extraction of cataract which is a sort of combination of couching and extraction, the whole idea of which is to extract the lens without disturbing the pupil. It is performed as follows: The patient being chloroformed and the speculum introduced, a large incision is made with a Von Graeffe's knife in the sclerotic about a knife and a half breadth away from the cornea, and the large MacNamara scoop is then passed in and the lens gently extracted in its capsule; atropine is then to be instilled and the eye bandaged up. The formidable part of the operation is the large size of the incision, but in Mr. Hall's experience the wound heals up very quickly without bad symptoms, although in one case he found that he had made the incision too small, and had to enlarge it with the scissors. There were no signs of iritis in any of the cases, although in two the capsule was ruptured, and in the third the incision being made too close to the cor-

nea the iris prolapsed and had to be excised. Surgeon-Major Hall is now having a blunt instrument made with a hook to it which will impinge upon the side of the lens, and then draw it out without pressing upon the back of the iris as the scoop does. It seems possible to insure in this operation as nearly perfect success as can be hoped for from any cataract-operation, the iris, the great bugbear to all eye-operations, being left practically undisturbed.

#### PRECAUTIONS TO BE ADOPTED IN THE REMOVAL OF RESIDUAL URINE.

At the meeting of the West London Medical-Chirurgical Society, held March 5, 1886, MR. E. HURRY FENWICK, after briefly commenting upon the various theories which have been framed to account for those cases of rapid death after the withdrawal of residual urine, laid special stress upon three great causative factors,—1. The reflex vaso-motor disturbance of the kidney set up by irritation of the posterior part of the urethra and the vesical nerve plexuses. 2. The introduction of septic material upon, within, or through the catheter. 3. The injurious effects upon the badly-nourished, thin-walled vascular system of the kidney and bladder by the sudden withdrawal of its accustomed water-pressure counterpoise. The precautions he adopted when he introduced a man, however young, into catheter life, were as follows: Absolute rest in bed for a week, cocainization of the prostate and membranous urethra, aseptic catheterism. The withdrawal, little by little, of the residual urine, and the replacement of the same by antiseptic solutions, such as hydrarg. perchlor. 1 in 10,000.

In the discussion that followed the reading of these papers—

MR. DUNN said that the interest of urethral fever was centred in the indefiniteness of its origin. Its accession did not, as experience showed, depend upon any condition which could be predetermined. It followed the simple passage of a catheter, and it was met with where there was lesion of the urethral tract. But he was inclined to believe that urethral fever was always the outcome of absorption. It was evident that in clinical features, in pathological appearances, in etiology, urethral fever and septicæmia were identical. Death from urethral fever was death from septicæmia, because the cardinal features of blood-poisoning were present at the post-mortem examination. It was not

necessary to admit that all rigors following catheterism were the result of septic poisoning. For some of these could be accounted for by attributing them to the manifestation of latent ague, and perhaps this would explain the rigors which have been regarded as having a neurotic origin. Sir James Paget has shown that the aguish attack may be provoked by an operation many years after the patient has suffered primarily from the disease.

MR. BRUCE CLARKE had not noticed any bad results in these cases where the symptoms could be attributed to nervous causes. The more, however, he saw of urinary fever the more he felt convinced that the disease was due to dirty catheters. In a case of residual urine which was under his care at St. Bartholomew's Hospital, the neglect of certain precautions which he always insisted on in regard to the cleanliness of the instruments was followed by serious results. Each patient under his care whose urine is required to be drawn off has a catheter for himself, which is kept, except during use, always in a solution of carbolic acid (1 to 100). He injected brine into the bladder when a tonic and antiseptic was required. He always used a new catheter in special cases. Internal urethrotomy deep down he considered was by no means a safe operation. In preference to performing this he would do external urethrotomy. He was surprised to hear Mr. Fenwick saying that the treatment of a case of stricture by electrolysis had been followed by a severe rigor. He had never in his experience, which was somewhat extensive of this treatment, met with this result, though he had seen one case in which there was a slight rise of temperature.

MR. KRETLEY agreed with Mr. Clarke that catheters should never be used where bougies would suffice. He cited cases to prove that in a considerable proportion of those in which rigors, etc., occurred, they followed the forcible use of larger instruments than the strictured urethra would bear. Deaths from pure nervous or reflex causes were excessively rare in connection with injuries to other parts, and he could not believe that they were frequent after interference with the urethra.

DR. POPE was sorry to learn from Mr. Fenwick that bacteria rejoiced in fat. This fact introduced some difficulty into the case when a lubricant for a catheter was required. He agreed with Mr. Dunn that latent ague was a cause of rigors after catheterism. He had a case under his care at present which bore out this hypothesis.

MR. EDWARDS, in reply, said that external

urethrotomy was more often followed by urethral fever than was internal, for in eleven cases at St. Peter's nine had rigors. Of the three cases he had brought forward, death was due in two to septic absorption. In the other, irritation due to instrumentation of the deep urethra caused reflex congestion of internal organs, accompanied by a rigor. This proving too great a strain for the central arteries, which were highly atheromatous, extravasation, followed by softening, occurred. In all three the urine was normal before the operation, and in the first and second the kidneys were found congested after death. The third case was the first death Mr. Edwards had had in about forty cases of internal urethrotomy. Why pyæmia occurred he could not say, as he took unusual antiseptic precautions by throwing into the bladder an iodoform solution, and by the insertion of an iodoform bougie into the urethra. There was no difficulty nor hitch in the performance of the operation. Concerning the question of ague, it was a well-known fact that patients who had lived in the East, or who had been subject to ague, were peculiarly liable to rigors after interference with the urethra.

#### *EUCALYPTUS AS A TOPICAL AGENT.*

In the *Cincinnati Medical News*, April, 1886, DR. P. T. WILLIAMS states that he was led to use eucalyptus as a topical application to the inflamed surface in cases of erysipelas by being told by an old sailor that he had been treated in that way by a physician in one of the East India Islands with most striking success. Dr. Williams reports three cases of erysipelas affecting the face and right leg, another the face, and another the scrotum, in which the application of the fluid extract of eucalyptus promptly arrested the itching and burning sensation, and the exudation of the peculiar gummy discharge.

In a case of caries of the tibia, with extensive inflammation of the skin, attended with the formation of numerous blebs and small ulcers, the happiest results followed upon the local use of the fluid extract of eucalyptus. In the cases of erysipelas it was applied, by means of a camel's-hair brush, every four hours. In the case of disease of the tibia he employed it twice daily. In each case appropriate internal treatment was made use of.

Dr. Williams's experience with eucalyptus as a topical agent, of course, is too limited to base much of an estimate in regard to its value, but the seeming beneficial effects fol-

lowing in the few cases he has mentioned, together with the data already published on this subject in previous issues of the GAZETTE, encourage one to believe that it can often be used with advantage locally ; that there can be obtained from it all the benefits that are to be had by the employment of the tincture of iodine, solutions of nitrate of silver, salts of iron, etc. ; and that it can be made use of when these could not be in consequence of some objectionable features attending their application.

THE PRINCIPLES AND PRACTICE OF SURGERY. By Frank Hastings Hamilton, A.M., M.D., LL.D. Third Edition.

New York: William Wood & Co., 1886.

Professor Hamilton's work on surgery was first issued fourteen years ago ; a second edition followed a year later, in which only the typographical errors of the first edition were corrected, and a few statements modified, so that a comparison of the first edition with the present one should give some idea of the advances made in surgery during this interval. At the present time, a decade and a half in the history of any of the sciences or arts is certainly long enough to establish the truth or to demonstrate the error of what has been proposed in theory, and to improve upon what has been found wanting. If there has not been either a theory proven or a deficiency filled, we truly have stood still.

In the author's preface to his last edition it is stated that in order to properly represent the progress of surgical science he has thoroughly revised the former editions of his book, and therefore it becomes our task to briefly note where, in the author's opinion, surgeons have improved in the practice of their art or advanced in the knowledge of their science.

The chapters on inflammation, abscess, ulceration, and gangrene are in no way added to or changed from the former edition of the author's work ; indeed, they are word for word the same. The chapter on wounds presents but few alterations, and only such as to more strongly emphasize the author's former views, in so far as they are opposed to the antiseptic dressing of wounds by the employment of the various antiseptic solutions, carbolic acid, bichloride of mercury, etc. Under gunshot wounds a brief account of President Garfield's case has been added. Exploration of the abdominal cavity, in cases of gunshot

wounds, for the purpose of searching for lesions of the various viscera, is not thought to be advisable.

The chapter on venereal diseases remains as in former editions, even to the author's opinion on syphilization. This method of treatment for syphilis was being strenuously advocated by Prof. Boeck about the time Prof. Hamilton's book first appeared. Since that time the fallacy of this means of treatment has been demonstrated, and syphilographers of to-day are united in the opinion that it is wrong in theory and useless in practice.

Chapter xiii., "Lesions of the Nervous System," is, with the exception of the section on tetanus, entirely new. It includes tetanus, shock, section of the nerves, stretching of nerves, and coccydinia. A short description of railroad shock is given, and the author very justly, we think, believes that while the spinal marrow or central nerves may be injured in this class of accidents, it is more frequently a primary injury inflicted upon the ligaments of the spinal column, and that secondarily inflammatory action may be propagated eventually to the meninges and marrow. This explanation is thought by Prof. Hamilton to account for the difference between the injuries to the spine caused by railroad collision and those caused by other traumatisms. Section of the nerves for neuralgic affections the author considers to afford only temporary relief, and resection, while it gives a longer period of freedom from pain than section, has, in his experience, never resulted in a permanent cure. In connection with this subject, there has recently been published a very able and exhaustive paper by Geo. R. Fowler, M.D., of Brooklyn, in the *Annals of Surgery* for April, 1886, entitled "The Operative Treatment of Facial Neuralgia." The following conclusions are reached by this writer :

"1. Neuralgias of the fifth cranial nerve, of peripheral origin, which have resisted methods of treatment other than operative, may be expected to yield to the operation of neurectomy of the trunk or trunks whose branches are distributed to the painful area. In this class of cases the neurectomy should be carried, if possible, to the point at which the nerve makes its exit from the cranium.

"2. Cases of central origin should be first submitted to a limited neurectomy, conjoined with nerve-stretching, in the hope that the process of regeneration thus set up, together with the rest gained by interrupting the centripetally-conducted stimuli, may favorably in-

fluence the diseased central organ. In case of relapse this may be repeated, providing the period of rest thereby gained corresponds to the length of time which Waller's investigations show to be usually occupied by the process of degeneration and regeneration. If no relief is gained, a similar operation should be performed upon all the divisions of the fifth nerve. This failing, a complete neurectomy of each division accessible should be done; and, finally, ligature of the common carotid may be tried as a last resort.

"3. In cases of doubtful origin, a complete neurectomy, followed, in cases which relapse, by ligature of the external and common carotid in turn, hold out the best prospect of cure.

"4. A complete neurectomy of the second division of the fifth necessarily involves the extirpation or destruction of the sphenopalatine ganglion; and to this fact, rather than to any intrinsic tendency of the ganglion itself to keep up the irritation causing the neuralgia, is to be attributed, in all probability, any increasing immunity from relapse claimed to have been obtained in those cases in which Carnochan's operation has been performed.

"5. No patient should be denied, other things being equal, the chance which any one or all the operations in turn may give him of escaping, even for a short time, the intolerable suffering incident to an intractable or otherwise irremediable facial neuralgia."

Esmarch's bandage for the arrest of hemorrhage is mentioned as one of the means which may be employed by the surgeon in suitable cases. Its advantages in certain cases are apparent, its disadvantages the author has not neglected to point out. It is to the latter we would especially direct attention. Acupressure, which in former editions received a detailed description of the various methods for its application, has in the present volume been omitted, since the author, in accordance with most surgeons, believes it should be abandoned. It is with great deference that we venture to differ with the opinion of Prof. Hamilton, obtained by a long experience, and especially upon such an important subject in surgery as the nature of the ligature to be used in the tying of arteries; but, although our experience has not been so extensive, it has, we think, been quite sufficient to thoroughly convince us of the very great superiority of the catgut ligature over the silk. His objection to the gut ligature is in its employment in ligating large arteries. In these cases he thinks it is unreliable, and

therefore secondary hemorrhage may occur. To say this unfortunate accident cannot take place when the gut is used is no more true than to say the same for the silk ligature, since experience tells us it has happened with both; but we do not believe there is any more liability of its occurrence when the gut is used than when silk is employed, and the many other advantages on the side of the gut are, at least in our opinion, so far superior to the silk, that we do not hesitate to utilize it upon every occasion when ligature is necessary.

The chapters on fractures and dislocations remain, without any essential changes, as in former editions of the book; indeed, it would be scarcely possible to improve upon this most excellent portion of Prof. Hamilton's work. The treatment of these lesions is briefly given, and it is on account of this brevity that we recommend it. No confusion or undecided statements are found, but the reader is at once informed what has, in the experience of the author, been found most successful in his practice, and the method of its application is clearly given. We may mention that, in previous editions, the treatment of fractures of the thigh by plaster of Paris was rather favorably spoken of. Now, however, Prof. Hamilton writes, "A further personal experience, together with the personal experience of others as it has come to my knowledge, enable me now to say that the plaster of Paris is not a safe or judicious dressing for fractures of the thigh, either for fractures through the shaft or for fractures near the upper or lower extremities of the bone, for fractures in children or in adults, for compound or simple fractures. Its use under all the circumstances named has been followed by a larger proportion of failures and disasters than any other plan of treatment known to me, such as great shortening of the limb, deformity, non-union, delayed union, gangrene, and death."

The treatment of fractures of the patella by wiring the fragments, with antiseptic precaution, is an operation that finds no favor with our author. From the unfortunate results that have occurred when the operation has been resorted to, he concludes that "such experience renders argument unnecessary."

Prof. Hamilton's opinion of gastrotomy is best given in his own words. He writes, "As a means of enabling the surgeon to dilate, by the finger or otherwise, a stricture of the pylorus, it is, in my opinion, not entitled to one moment's consideration.

"Finally, when made for the purpose of removing a portion of a cancerous stomach, it

is simply an ante-mortem dissection, and has no proper place in surgery.

"Both of these latter statements are made after a study of the reported cases, and with a just appreciation, I hope, of my responsibility to suffering humanity. In neither case can there be anything more than an approximate knowledge of the actual pathological condition and complications, and in neither case can anything but temporary relief be afforded, and that at the imminent risk of immediate death, or of death resulting directly from the operation."

A section on "Lesions of and Operations upon the Gall-Bladder" has been added to the present edition. It treats of abscess of the gall-bladder, fistula of the gall-bladder, and obstruction, concerning which he believes that "in most cases the causes of obstruction will be found to be beyond detection, and their removal beyond the skill of the surgeon." Cholecystotomy, estimated from the ratio of mortality, is thought now to be "accepted as one of the legitimate alternatives of surgery." Cholecystectomy is considered to be a questionable operation. Cholecystenterostomy is said to be "entitled to no further consideration than its mention, and to say that it proposes to substitute a very unsafe and uncertain operation for one which is comparatively safe and certain in its results."

The treatment of stricture of the urethra, after the method especially practised and recommended by Dr. Otis, is strongly opposed by Prof. Hamilton, and he is in perfect agreement with the views of Dr. Ranney, whom he quotes to sustain his opinion. From our reading of Dr. Otis's last work on "Stricture of the Urethra" we are inclined to look more favorably upon his method of treating this lesion. The very extensive experience and the almost constant success in the results of the operation obtained by Dr. Otis, would seem to show that by adopting his procedure we would gain much in our treatment of these cases.

As regards Bigelow's method of operating for vesical calculus, Prof. Hamilton thinks "it would be premature to declare for it unquestionably, at present, superiority over all other methods, notwithstanding it has received the approval of our best surgeons, and has satisfactorily borne the test of considerable clinical experience."

Dolbeau's method for the same affection is thought to have "very little to recommend it, and has not been generally adopted." The method of operating for stone by the supra-

pubic operation remains as it was written in 1872. The procedure of elevating the bladder above the pubes by distention of the rectum should, we think, have been referred to. This operation was first performed in 1880 by Petersen, of Kiel, and since by other surgeons, among whom Sir Henry Thompson may be referred to as one of its most ardent advocates, and in his recent monograph upon this operation he writes, "The high operation for opening the bladder has, in my opinion, been rendered so safe and efficient by certain modifications recently made, chiefly by Professor Petersen, of Kiel, as to deserve the careful attention of all practical surgeons."

Digital exploration of the bladder, performed by means of perineal section, and adopted by Sir Henry Thompson, has not been mentioned by Prof. Hamilton. This oversight is unfortunate, for we believe there is no method so certain to remove the difficulties of arriving at a correct diagnosis, in cases of tumors of the bladder, as the one proposed by Thompson.

Oöphorectomy, or spaying, is briefly described, and from the results obtained in its performance, of the cases published, the author considers the mortality much too great to justify the operation.

Alexander's operation for shortening the round ligaments is disapproved of in strong terms, and, after describing the method of operating, Prof. Hamilton writes, "It seems to me incredible that any person who has acquired even the rudiments of surgical science should perform an operation so unsound in theory, and plainly so unsafe in practice." A paper published in the *Boston Med. and Surg. Jour.* for April 29, 1886, by F. B. Harrington, M.D., discusses this operation. He gives a table of the cases so far reported and the results, which is again an evidence of the want of agreement among surgeons. Thus, there are twenty-two operators who have reported cases, among whom seventeen consider the operation good, four are doubtful, and one believes it bad. The number of cases treated are one hundred and forty-two. Of these, one hundred and twenty-seven are said to have resulted good and fourteen bad. One death only is reported to have occurred in the one hundred and forty-two operations. These results are certainly not in accord with the opinion of Prof. Hamilton, and it seems to us he has been somewhat hasty in forming his conclusions.

Emmet's operation for laceration of the cervix uteri is said to be "not always successful.

It is attended with the danger of sometimes giving rise to a serious and even fatal metritis and perimetritis, and the laceration is pretty certain to be renewed in a succeeding labor."

Laceration of the perineum, according to Prof. Hamilton, whose opinion is based upon an early obstetrical experience and a late surgical experience, is believed, at least the more graver forms of this lesion, to be much more common now than formerly, and this increase he thinks is owing to the more frequent use of the forceps and anæsthetics in labor. For very good reasons, the primary or immediate operation in the treatment of this lesion is opposed. The secondary operation is advocated, and preference is given to silk ligatures.

The chapter on anæsthetics is a very valuable addition to the present volume. Prof. Hamilton thinks "ether ought generally to be preferred to chloroform." The internal administration of stimulants or opiates, either before or after giving anæsthetics, is not thought to be of any benefit. Local anæsthesia, produced by cold or the spray, is considered very limited in its application, and frequently in the first period of their application they occasion pain, so that most patients are willing to submit to the operation without their employment. Cocaine hydrochlorate is mentioned as one of the most recent local anæsthetics, and it is thought that "the intelligent surgeon, understanding its physiological action, will have no difficulty in selecting for its employment the appropriate cases."

Prof. Hamilton has added a supplementary chapter to this edition of his book, entitled "*The art of primary union, or union by adhesion in large wounds, with a consideration of the value of antiseptics in these and other wounds.*" Four conditions are said to be necessary to insure "primary union," or "union by adhesive inflammation," in large wounds. These terms are considered synonymous.

1. "A good, or at least an average, state of the general health, and especially the absence of any systemic infection or dyscrasy."

2. "The removal of all foreign bodies from the wound."

3. The coagulation of the lymph, which is indicated by the glazed appearance of the surface, therefore the wound is to remain open until this appearance is presented.

4. Precaution must be taken not to do any unnecessary violence to the parts, since it tends to increase inflammatory reaction, "and

to carry it beyond the limitations which are assigned to the effusion of emplastie lymph."

Prof. Hamilton further adds, "I believe also that a strict compliance with these rules constitutes the only grounds for the superior success of some surgeons, as compared with the success of others, at the present day; and if their success is greater than that of surgeons who fifty or one hundred years ago practically applied these rules,—and I am willing to concede that it may be, although it is not proven,—it is because they have more exactly complied with the conditions named."

"What treatment," our author asks, "either ancient or modern, has presented a better record than this furnished by Alanson, Syme, Liston, Percy, Lucas, and, so far as we know, by the faithful disciples and distinguished advocates of their practice? It is scarcely necessary to remind the reader that these results were obtained before the introduction of anæsthetics or of antiseptics." From these quotations it is very evident that Prof. Hamilton does not believe in antiseptic surgery, as introduced by Mr. Lister, but it is, he says, "through the agency of one man, Mr. Lister, the practice of union by adhesion was happily restored;" and, again, "the influence of Mr. Lister, backed by his specious theories, secured a return to the old practice of the advocates of primary union in all its essential details, and to this it added antiseptis." This addition of antiseptic solutions is believed by our author to act purely as "moderate stimulants and astringents." The germ-theory is said to be "only a theory, and one which is far from being universally accepted."

The conclusion to which Prof. Hamilton is brought from his investigations of antiseptic surgery is as follows: "The conclusion to which we are brought is, that while we are indebted to Mr. Lister for having restored confidence in union by adhesion, it seems equally certain that his excellent results have been obtained, not by a literal compliance with the rules which are the logical deduction from his theories, but by his strict enforcement, in the practical application of his theories, of certain other conditions, which he seems to regard as accessory and incidental rather than of paramount importance."

The differences of opinion in regard to antiseptic surgery are still in existence. This method of treatment from its beginning met with much opposition; but while it has not yet become universally adopted, it has, however, wonderfully added to its ranks, and has gained a foothold in surgery so firm that we

believe it will eventually supersede every other method. We will not venture to assume the position of a judge; in fact, we only speak from our own experience, and are convinced only from our own results. It is on the ground alone of success that we must give credit to antiseptic surgery for better results than we ever obtained without it.

We stated in our first paragraph that the object we had in view was to ascertain what advances surgery has made, in the author's opinion, during the interval between the first and last editions of his book. We have made the comparison, and the reader has the result. Some additions may have been overlooked, but we have endeavored to give all, and our own conclusion, we regret to say, is that, if we are to judge of the progress made in the "Principles and Practice of Surgery" upon the evidence presented by Prof. Hamilton, it has advanced but little.

In concluding our notice, we wish to speak of Prof. Hamilton's work as a whole, and too much praise cannot be given to it for reliability and clearness. The student, for whom the book is more especially written, cannot have a better guide to lead him in the paths of surgical knowledge, and the practitioner will seldom regret having followed the advice given by our author.

J. H. C. S.

THE DIAGNOSIS AND TREATMENT OF DISEASES OF THE EAR. By Oren D. Pomeroy, M.D., Surgeon to the Manhattan Eye and Ear Hospital, etc. 8vo, 413 pp. One hundred illustrations.

New York: D. Appleton & Co.

The fact that Dr. Pomeroy found it necessary to publish a new edition of his work in a little over two years, indicates that the first edition received its due appreciation at the hands of the profession. Evidences of careful revision are frequent, and the changes made represent the advances in the field of otology since the first edition was published. Twenty-nine pages of reading matter and several illustrations have been added, while the beauty of many of the old wood-cuts has been enhanced by recutting.

As was the case with the first edition, the author saw fit to omit a chapter on anatomy and physiology of the organ treated. This is to be regretted, as his descriptive ability might have served him advantageously to present a clear and concise study of a subject usually very difficult to understand. The work begins with a description of the instruments used in the examination of the ear, with hints as to the modes of testing the hearing and an

enumeration of the appearances of the normal drum membrane. The diseases of the auricle are next treated, this being followed by a chapter upon the diseases of the external auditory canal. Before entering upon the discussion of the diseases of the middle ear, the author wisely gives a *résumé* of the affections of the post-nasal space, indicating the methods of treatment to be employed for the eradication of the primary troubles located in this position, so often overlooked. Mastoid affections next receive attention, but few pages, however, being devoted to their consideration. Under the head of "Unclassified Affections" twenty subjects are considered, the syphilitic diseases being included in the series. The book ends with a few pages upon ear-trumpets, the audiphone, and the Japanese fan.

The author's extensive hospital facilities and private practice are used to great advantage to illustrate the value of the therapeutic measures recommended, his vast experience enabling him at the same time to speak in a manner which at once conciliates the confidence of the reader.

As an aid to the general practitioner, Dr. Pomeroy's work is exceedingly valuable. While not exhaustive, which its size, of course, does not permit it to be, it is sufficiently complete to render great assistance in any variety of cases that may be met with. Each subject is subdivided into *subjective and objective symptoms, etiology, diagnosis, prognosis, and treatment*, and, unlike the majority of works, these subdivisions are so strictly adhered to and so well defined that the busy practitioner may be certain of finding under each subheading all the information that the work affords.

The style is terse and to the point, although the frequent and sudden changes from the purely descriptive to the imperative might be considered as objectionable. A few corrections are still needed, among which "Noyes's Polypus Forceps," "Sass's Spray Instrument," and "Cannula" may be cited. These will surely receive the author's attention in the third edition.

We can heartily recommend Dr. Pomeroy's work to the profession, and wish it all the success it deserves.

A GUIDE TO THE PRACTICAL EXAMINATION OF URINE.  
By James Tyson, M.D. Fifth edition.  
Philadelphia: P. Blakiston & Co., 1886.

It has, we believe, been less than ten years since the first edition of this small practical manual was given to the world. Books on

diseases of the kidney and of the chemistry of the urine and allied subjects are about as plentiful as herring in season on the coast of Scotland; but the success of this brochure shows that there is always room for one more fish, provided said one be of superior flavor. The present volume has been brought by Prof. Tyson thoroughly up to the advances of the day, so that the fifth edition is even more satisfactory than was the first, and we have no doubt will have equal success.

A REFERENCE HAND-BOOK OF THE MEDICAL SCIENCES, EMBRACING THE ENTIRE RANGE OF SCIENTIFIC AND PRACTICAL MEDICINE AND ALLIED SCIENCES. By various writers. Edited by Albert H. Buck, M.D. Volume II.

New York: William Wood & Company, 56 and 58 Lafayette Place, 1886.

Some months ago we reviewed at considerable length the first volume of this work, pointing out its general scope, and commenting upon its execution. It seems scarcely necessary to do more than to state that the present volume reaches to the end of the letter "e," and that the reader and probably the subscriber also begins to appreciate the comicality of calling this great encyclopædia a hand-book; and we can only reiterate our heartfelt wishes that there was some way of hanging publishers, editors, writers, printers, printers' devils, and all concerned in this misusing, defiling, and bringing to shame what would be called in England the queen's English, but which in this country bids fair to become a mere democratic lingo.

Once having crossed the shakily, tumble-down, miserably put-together, uncouth, wretched bridge of a title into the main pastures of the book, we find the same excellences which we noted in the first volume. The articles upon Mineral Springs are very full and very valuable. The therapeutic articles by Dr. S. Nicholls are condensed, but show a very thorough knowledge of medical literature, and seem to us to be written with judgment. The pictorial features of the book are well maintained by plates for show and wood-cuts for use. The medical practitioner of æsthetic turn and limited means, to whom fortune has assigned a copy of the book, may well cut out the chromo-lithograph of dogwood and frame it to ornament his office. Possibly it is just as well to have this chromo-lithograph inserted in the book as it would be to distribute it as prizes. A picture, which, on account of the pious, resigned expression on the face of the victim, might be used for circulation among the chronically and hopelessly afflicted,

is that of Elephantiasis, in which the trunk and face of an hysterical female are attached to an enormously hypertrophied leg. With closed eyes and folded hands she is commending to the notice either of the reader or of a watchful Providence her misfortunes and her resignation.

To show how carefully the out-of-the-way corners of the medical field are cultivated, we may mention that Dr. Greenleaf's very elaborate article on the examination of recruits for the army occupies no less than fifteen pages, which, on account of the size of the page and the fineness of the print, is enough space for a small treatise.

MATERIA MEDICA AND THERAPEUTICS. By Charles D. F. Phillips, M.D.

Philadelphia: Blakiston, Son & Co., 1885.

In 1882, Dr. Phillips published a work upon the inorganic substances of the materia medica, and, as the pages of the book before us are devoted to the consideration of the materia medica and therapeutics of organic substances, the two volumes form a complete treatise on materia medica. There are in the present book over one thousand pages, occupied with a large, heavy-leaded, pleasant type, and much waste of blank paper between the paragraphs and larger divisions. To those who are accustomed to the artistic medicine books of North America, this thick, stumpy, heavy, unhandy method of publication, so frequent in Great Britain, is especially annoying, but we suppose it is hopeless ever to expect any artistic sense in a people whose ancestors were nurtured among the hyperborean fogs of Frisia. A little care would have reduced, probably by some hundreds of pages, the thickness of the book, much to the comfort of the lap of the student.

Coming to more important matters, we find little to complain of. The style is clear, the author reasonable, and good use has been made of the standard treatises upon the subject: Dr. Phillips is especially to be commended for the honesty which causes his pages to be plentifully spotted over with the names of well-known authors of leading therapeutic treatises. He does not appear to have himself largely read the original literature of the subject, at least as it exists in the German and French languages.

We observe, among other things, that the American drug *rhus toxicodendron* receives quite a lengthy notice, and is particularly commended in "herpes zoster, pemphigus, and eczema, especially when accompanied by

burning or itching sensations ;" . . . "in erythematous erysipelas, particularly when vesicles and bullæ develop, this is a good remedy." Dr. Phillips also commends rhus in chronic rheumatic affections of the fibrous tissues, and in the after-state of acute rheumatism when the temperature has fallen, but the patient still complains of stiffness and wearing pains. In these cases he applies the tincture in the form of a liniment, and gives it internally in from 5- to 10-minim doses from two to four hours. We believe the drug has been quite largely used in this country by irregular practitioners, and have ourselves employed it internally in four or five cases of subacute rheumatism, but after thorough trials failed in any of these cases to obtain any other effect than irritation of the stomach and consequent loss of appetite.

The book of Dr. Phillips is one evidently intended for students, and we suppose will have in its own country a satisfactory sale. But there do not seem to us in it any sufficiently original features, or any sufficiently active excellence to give it headway in the face of the standard treatises which at present hold the American student market ; nor, indeed, can we see any reason why the American practitioner should add it to the lists of his book-shelves. The activity of medical writers, stimulated as it is by the greed of the publishers, produces now yearly such an overwhelming mass of literature, good and indifferent, that the doctor must needs look carefully as to his purchases. There is an abundance of books of original merit to absorb all the spare cash possessed, except by the most fortunate of the profession. Further, the purchasing zeal of the American public will not be stimulated by the fact that the price of the present volume is \$7.50, so that if the two volumes necessary to complete the work are bought, the cost will be one-half more than that necessary for the United States Dispensatory, which probably contains nearly twice as much matter as the two volumes of Phillips.

**COCA, COCAINE AND ITS SALTS; THEIR HISTORY, MEDICAL AND ECONOMIC USES, AND MEDICINAL PREPARATIONS.** By William Martindale, F.C.S., etc. London: H. K. Lewis, 1886.

This little book is the biography of coca. It gives us its early history, and all the superstitions in regard to it, and we had no idea how many superstitions there were. It seems to have been a sort of royal tobacco. The Incas of Peru chewed it, and the priests,

having no cuspadores, expectorated its juices upon their burning victims. If a citizen became great and renowned, only then did the Inca offer him a chew. They, even, so far from throwing away their quids on entering their places of worship, considered that the divinity was kindest to the man whose cheek bulged out the most. They place it at the present day in the mouths of the dead,—even corpses like it,—and the author quoted irreverently goes on to say, "And when a Peruvian Indian on a journey falls in with a mummy, he presents to it some coca-leaves." Of course, with us, one might take very long journeys and never fall in with a mummy, or fall out either. And, as though the above specimens of literature were not enough, we have a chapter on "Coca in literature." The author somewhat sadly says, "Milton appears not to have known of it." Cowley evidently did, and produced more than a page of dreadful verse, but if one chews some of this leaf he may read the poetry without pain. Milton's case is more sad, for Milton was a poet. He never knew of coca; if he had he might have shown us Lucifer himself using it to allay his hunger in the realm where fire is plenty but food scarce, or in paradise the Erythroxylon Coca might have figured as the tree of life. Had our first parents partaken of its leaf no hunger would have impelled Eve to the fatal apple. She would have needed no lunch, and posterity would have remained sinless and pure.

E. W. W.

**A TREATISE ON BRIGHT'S DISEASE OF THE KIDNEYS: ITS PATHOLOGY, DIAGNOSIS, AND TREATMENT; WITH CHAPTERS ON THE ANATOMY OF THE KIDNEY, ALBUMINURIA, AND THE URINARY SECRETION.** By Henry B. Millard, M.D., A.M., Member of the New York County Medical Society, etc. Second edition. Revised and enlarged.

New York: Wm. Wood & Co., 1886.

The author dedicates his work to Drs. J. M. Charcot and M. Debove. The volume, he tells us, is the result of twenty-six years of hospital and private practice and of laboratory study-trial. The illustrations were drawn by himself, with a few exceptions, and he employs the word albumin exclusively throughout the book, leaving albumen to designate the white of the egg. After devoting seven chapters to the anatomy, etc., of the kidneys, chapter viii. discusses the "significance of the existence or non-existence of albumin in the urine,—a question of growing interest and of the deepest importance." That there is a physiological appearance of albumen the author fully believes, independent of its transient ap-

pearance after indigestion, great mental or physical effort, etc. This statement is at variance with the belief of many authorities, who only admit its appearance in persons "apparently" in perfect health. The author, after a long discussion, says, "Where it occurs frequently and in such quantities as the one-fortieth to the one-tenth of one per cent., it may be regarded in the majority of cases as an evidence of renal lesion."

The chapter on "the tests for albumin" goes very thoroughly into the subject. He quotes Méhu as saying that the most albumen he ever found was in less proportion than two and a half per cent.; the common error of overstatement arising from the fact that urine containing 1.5 per cent. will seem to become almost solid. The author rejects in this edition the picric acid test among others, because it produces precipitates "with the parapeptones and all protein compounds." This, however, does not destroy its value as a ready test. So long as no one proves that it fails to precipitate albumen, if no precipitate be found by picric acid, then it has answered its purpose if precipitation occurs; further tests may be employed. After a careful study for two years, the author settles on four tests as best of all, and wants no better, unless it be one to show with precision the difference between albumen and mucin. The four tests are "nitric acid, heat, Tanret's test," and his own test of "phenic acid and acetic acid and potash." In the nitric acid test he pours the urine slowly upon the acid by a pipette. This test he has proved capable of showing one part in 100,000. Tanret's test of the double iodides of mercury and potassium, to be made by the formula given on page 62, will show, the author claims, one part in 250,000, while the author's own test, "which gives him great satisfaction," as our own tests always do,—to ourselves,—"shows one in 300,000 undoubtedly."

The question of casts, their nature, mode of formation, and significance, with general directions for examining for them, is carefully discussed.

The author concludes, from a careful study of Bright's writings, that the name Bright's disease is in general applicable "to those diffuse inflammations of the kidneys accompanied by albuminous urine, either constant or intermitting." He himself considers all varieties of nephritis under three heads,—*"Croupous, Interstitial, and Suppurative."*

In croupous nephritis the author believes the chronic form to be seldom a sequel of

the acute. He doubts whether it ever arises from the acute nephritis of scarlatina for instance. This opinion he subsequently modifies somewhat, and says (page 162), "I am constrained to believe that if the acute nephritis be imperfectly cured, although the symptoms may be wanting for a long time, sooner or later manifestations of chronic nephritis may occur." Malaria he recognizes as a common cause, special irritants, as ginger and cantharidal poisoning, while he doubts the direct action of alcohol in excess as a factor. In regard to the malarial cases of nephritis, he notes that in them albumen is never absent.

Interstitial nephritis the author divides into acute and chronic, though admitting that the recognition of the acute stage will be generally retrospective, like the Hibernian's "prophecy after the event." The acute form he believes to be "due in nearly all cases to cold," or the extension of chronic or severe acute cystitis. We are left by his language somewhat in doubt whether the acute cases "nearly all" so produced are the acute cases which form the first, rarely discovered stage of the chronic cases or not. Damp, cold, and catching cold are the principal causes given by the author. Heredity limits itself as a factor to gouty, tuberculous, or syphilitic cases. Malaria, with repeated chills, in his own experience, has formed part of the history of a considerable number of patients, while he "has not been able to trace a single case to the direct effect of over-use of alcohol." The author recognizes the fact that the gouty paroxysm is frequently associated with albuminuria, and quotes from Charcot, "Albuminous nephritis, when dependent upon gout, is distinguished especially by its apparent benignity and its slow evolution." The question of the action of lead on the kidney is inquired into, and there is a very interesting chapter on the topics of "Nephritis without Albuminuria," and of "Epithelia in the Diagnosis of Nephritis."

Part II. is upon treatment. In acute croupous nephritis, rest, diet, diaphoretics, are recommended; for producing action of the skin, the author uses the hot-air and vapor-bath and jaborandi. When there is insufficient power of left ventricle, convallaria majalis and digitalis. Caffeine ranks with digitalis as a diuretic and heart-tonic; "in venous stenosis, valvular disease, and dilated heart it is better." The author calls attention to the oft-forgotten fact that to derive benefit from saline diuretics the solution must be of less specific gravity than the blood

itself. Tinct. ferri chl. alone, or with digitalis, he gives in feeble heart and impoverished blood, sometimes with cantharides. This remedy, however, he never uses in early periods, but after acute symptoms have subsided. As to the effects of nitro-glycerin, he admits his inability to account for its beneficial action on any plausible theory, but suggests that it acts "through the renal ganglia entirely." In acute nephritis he has not employed it, but in a case of polyuria, with tense, hard pulse, he gave a patient by its means great relief.

The author then gives his opinion of the mercurials, considering them as capable, either "alone, or in combination with other remedies and measures, of curing many cases of acute, and some even of chronic nephritis." He employs generally the mild chloride in interstitial and the bichloride in croupous nephritis, but occasionally the reverse. Though he can give no reason or indication for so doing, it is evidently from instinct that he does so. The mild chloride he gives, triturated with 100 parts of milk-sugar, in doses of  $\frac{1}{10}$  to  $\frac{1}{20}$  of the salt every two or three hours.

Of the bichloride, he uses a trituration of which 10 grains contain  $\frac{1}{1000}$  of a grain of the salt. This is his usual dose, though larger can be given. He knows (page 203) "that the possible effect of such small doses will be regarded by many with incredulity, but their value has been demonstrated, . . . and the recognition of the efficacy of these doses is a matter of simple and assured truth." And adds, "Particularly is this shown in those cases in which the dual action of drugs is manifest, as in the action of corrosive sublimate upon the kidneys in health and disease." And again, page 205, "It is a matter of no slight interest to consider that while corrosive sublimate will often correct pathological conditions characterized by albumin, bloody urine, or suppression, the same remedy, taken in health in toxic doses, often produces those very conditions. I do not propose to descant upon the merits of any theory, still less to support any supposed law of cure." The subject of cantharides gives the author a chance to indulge in somewhat similar remarks. Nitric acid, either with or without mercury, he finds useful, especially in the gouty kidney. Arsenious acid he believes should be a useful remedy "from its action on the kidneys when taken in poisonous doses." In short, the author goes over the whole list of usual and unusual remedies, giving them a full and intelligent discussion.

In the treatment of chronic interstitial nephritis, the questions of climate, diet, general hygiene, mineral waters, etc., are entered into. As to special remedial measures, he would restrict potassium iodide to syphilitic, lead-poisoned, or gouty cases. He suggests that lead also might prove a good remedy, being evidently impressed with the idea that there is but one way of discovering "cures," viz., that the bane is the antidote. But of all remedies after the mercurials he considers the chloride of gold and the chloride of gold and sodium, given in doses of from  $\frac{1}{10}$  to  $\frac{1}{100}$  grain three or four times a day, as perhaps the best. With him they have "proved of great value."

Throughout the book one is struck by the excellent ability of Dr. Millard as a writer: his style is enticing and his sentences forcible. The illustrations of the book are good in their way, the print and type of the best, and one cannot fail to gather some new ideas on the important subject of which it treats by its careful perusal.

### *THE REMOVAL OF SUPERFLUOUS HAIR BY ELECTROLYSIS.*

To the Editors of the THERAPEUTIC GAZETTE:

GENTLEMEN:—A report of the following case will be of special interest to all those who read the article on the "Removal of Superfluous Hair by Electrolysis" in the March number of the THERAPEUTIC GAZETTE.

The method which I employed was, with some modifications, the same as that given in that article. Instead of placing the sponge electrode (+) in the patient's hand, I applied it at the nape of the neck, and kept it there constantly, while the electrode needle-holder (—) had an attachment, by means of which I could make or break the current at any moment. I was thus enabled to get along with fewer cells and without loss of time. The pain caused was of no consequence whatever. The needle used was a plain steel sewing-needle of fine quality.

Mrs. W. had for the last ten years been annoyed by a strong growth of hair about her chin and upper lip. She had tried all conceivable remedies, with the result of only increasing the growth through the stimulation thus produced, so that when she came to me for relief she had a beard that would have done justice to a man.

It at first appeared almost hopeless ; but, as she was so very anxious to have the growth removed, I determined to undertake the case.

The estimated number of hairs to be removed was fifteen hundred to two thousand, but I soon found that my estimate was too small, the number far exceeding two thousand.

At the first meeting I took out about one hundred hairs, with an average allowance of ten seconds for each hair, and immediately afterwards washed that part with a weak solution of acetic acid, so as to neutralize the alkaline effect of the products of the (—) electrode.

On her return to the office the next day, I found the reaction so very slight that I ventured to take out over three hundred hairs at one sitting with equally good results. The following days I even exceeded this number, so that in nine sittings every objectionable hair on her face was removed.

In not one instance did I apply the needle twice to the same hair, and always applied it to about fifty or more before I stopped to extract them, which is very quickly done, the hairs after the electrolysis being perfectly loose.

After a lapse of about six weeks I found a return of about three per cent., which, after similar treatment, were also completely destroyed, so that now, after seven months, the face of the lady is in excellent condition.

Respectfully,

JAS. A. BACH, M.D.

MILWAUKEE, March 31, 1886.

#### RHEUMATISM AND CHOREA.

To the Editors of the THERAPEUTIC GAZETTE:

GENTLEMEN :—Having read several discussions of the question whether chorea was complicated with or dependent upon acute rheumatism, I wish to relate a case falling under my observation. Ida R., aged 15 years, was brought to my office suffering from the worst attack of chorea which I have ever witnessed, the power of speech being lost, and all the voluntary muscles seeming to be involved. I administered strychnine, arsenic, and iron in the usual manner, in conjunction with hydrate of chloral and the bromides. I afterwards visited her at her home in the country, and could see no improvement in her case for a week, until she succeeded by motions and gestures in informing me that she had pains in her wrists and ankles, when I began the use

of salicylate of sodium in 20-grain doses every three hours, and from that time I noticed a marked change for the better at every visit. I had in the beginning of the case endeavored to obtain the succus conii, having seen it highly recommended in the London *Lancet*, but did not succeed till the third week of my treatment ; and the chloral and bromide at that time seeming to have lost its efficacy, I began the use of it in 1-drachm doses four times a day, and its control over the disease seemed to be miraculous. The first prescription for the case was made March 16, and on April 20 there were no symptoms of the disease present. My experience with the succus conii fully convinces me of its value in the treatment of this distressing disease.

GEORGE C. IRWIN, M.D.

SABETHA, KANSAS.

#### A SPECIMEN OF A GERMAN MIXTURE.

To the Editors of the THERAPEUTIC GAZETTE:

GENTLEMEN :—In your issue of April 15, page 286, there appears an article headed "A Specimen of a German Mixture," and stating that up to recent times it was not infrequently prescribed by "heroic German physicians." I have my doubts whether a "heroic" or not heroic German "*physician*" ever prescribed such a mixture, but it is possible it has been prescribed by German *quacks*, as we have German as well as American quacks in the profession, and certainly you will find the largest percentage in the latter.

A regular German *physician* will never use such a second-handed Latin as appears: "Fiat *místura*, digere secundum artem et filtra." He would say, "Misce, digere lege artis et filtra."

Yours truly,

DR. H. HAHN,  
German physician.

HASTINGS, MINN.

##### SAUSAGE AND PUTRID MEAT POISONING.

To the Editors of the THERAPEUTIC GAZETTE:

GENTLEMEN :—May I make the following communication through the THERAPEUTIC GAZETTE? I desire to collect instances of sausage poisoning, or putrid meat poisoning, and should be very grateful to any members of the profession who, having knowledge of any such cases, will be kind enough to com-

municate to me a brief statement of the manner of poisoning, the symptoms, and results. The discovery of ptomaines, and of the probable rôle which they play in tainted meat poisoning, has invested this subject with additional interest, while its relations to sanitary science should secure for it at all times more attention than it seems to receive in our medical literature. With a view of collecting cases for comparison and report, I have made this request, and the assistance indicated will be greatly appreciated.

Very respectfully,

J. U. BARNHILL, M.D.

164 E. TOWN STREET, COLUMBUS, OHIO.

#### DIAGNOSTICIAL LAPAROTOMY.

At the recent meeting of the American Surgical Association, held in Washington, DR. CHRISTOPHER JOHNSTON, of Baltimore, read a paper with this title (*New York Med. Journ.*, May 8, 1886). He said this operation was as ancient as our race, but in early times was always practised on the cadaver. The *lex regia* of Numa Pompilius required it to be performed upon any woman who died in the twenty-seventh week of pregnancy unless reliable signs showed that the foetus was dead. The first operation on the living subject was probably performed about the year 1600. In abdominal diseases the question arose, How should the seat of the pathological change be reached? The answer was laparotomy, which made the diagnosis positive in cases of doubt, and was preliminary to other operations which might be required. If the surgeon had no right to refuse to give air to a fellow-creature becoming asphyxiated from obstruction in the air-passages, had he the option of refraining from surgical interference when the primæ viæ were obstructed in their functions? The answer to this question hung first upon the diagnosis, sometimes upon the record of the past, and not infrequently upon the wise boldness of the surgeon. The propositions, then, were: First, that for abdominal surgical affections all possible operations ought to be attempted after the establishment of a precise diagnosis; and, second, that when a just diagnosis could not otherwise be reached, it might and ought to be sought out by an exploratory incision. The mortality of abdominal incision without complication was low. The record with regard to diagnostical laparotomy was very brief, for, as a rule, when the surgeon approached the case the diag-

nosis was already nearly positive. The gravity of the operation was largely determined by the time at which it was performed. The abdominal incision intentionally diagnostical was fraught with so little comparative ill consequence that its high value or necessity might be fairly alleged as an established and proper aid to diagnosis. Of all operations involving laparotomy, those involving the uterus and its appendages probably filled the largest space. Next we had those involving the alimentary tract. Speaking of the Cæsarean section, the speaker said that, comparing the mortality of this operation in former days with the mortality of the Porro-Müller operation, we found that, while shock and other dangers were greatly increased in the modern operation, the mortality remained about the same. The old operation was, as a rule, done under objectionable surroundings by inexperienced operators, while the modern operation was done by experts with the best surroundings. We had yet to see what the old operation would accomplish when the same safeguards were thrown around it as were given to the newer operation. When was exploratory laparotomy called for? It should be stated that to a certain extent every laparotomy was diagnostical. Two great classes in which exploratory laparotomy was demanded or permissible were to be recognized: First, all sorts of cases in which the diagnosis could not be made without its aid. Second, all cases in which, a diagnosis having been made, no definite line of operation could be marked out, and no abandonment of active measures be entertained or justified. As in these cases laparotomy held the key in all cases of doubt, both as to what was the matter and what was to be done, it should be called upon to surrender that key.

DR. A. VANDERVEER, of Albany, said that simple incised wounds of the abdomen, without injury to the abdominal organs, would usually heal without difficulty, even if left to themselves. The mortality was very slight. Even when the injury was more serious, recovery often followed. The cases which gave us anxiety were those in which the bowel was injured and its contents escaped into the abdominal cavity. These patients died inevitably if nothing was done. In these cases laparotomy should be performed. This view was often opposed by the friends of the patient, and often by the attending physician. We had much to do in the direction of teaching the profession and the public the importance of early operation in these cases. Cases were cited of gunshot injuries of the intestine and

of rupture of the intestine produced by external violence, in which the operation might have saved life if it had been permitted by the friends of the patient. The operation, as a rule, would not be permitted until the patient was in collapse, and it was then too late. If possible, the operation should be done in cases in which it would prove successful, so that the surgeon might have an argument in favor of his recommendation, and the masses must be educated to the necessity of laparotomy in the cases referred to. As to the mode of operation, the incision in the median line was by far the best. In some cases it would be impossible to reach the seat of disease by any other incision. In the closing of the wound some recommended several lines of sutures, uniting the different layers of tissue separately. The speaker did not believe that this was any advance on the old method of using sutures, including all the layers of tissue. Where there was great distention of the bowel with intussusception, the discovery of the seat of trouble was greatly facilitated by a procedure which he had seen Tait adopt in such a case. He opened the distended coil of intestine, permitted the gas to escape, and then closed the opening with sutures.

DR. J. EWING MEARS, of Philadelphia, said that, in considering diagnostical laparotomy, he would arrange the subject in this manner: In the first place, we should use external manipulation; second, internal examination where this was possible; third, aspiration; and, finally, laparotomy. He regarded laparotomy as much the most serious of all these methods. In this discussion the subject of laparotomy as a means of treatment did not call for consideration. The more experience he gained, the greater was his conviction that the abdominal cavity should not be opened without due consideration. Death was a severe penalty to pay for the perfection of the diagnosis. The tendency at the present time seemed to be in favor of opening the abdominal cavity rather than cultivating that essential skill by which the diagnosis might often be made without resorting to operation. Tait's assertions that opening the abdominal cavity was a matter of very little consequence had led many of the younger members of the profession to perform this operation without due consideration. He had at present under observation a case in which he had made out the existence of an obscure abdominal tumor, and had determined that the patient was suffering, possibly, from carcinoma. He had not felt it his duty to perfect the diagnosis by

opening the abdomen. He had carefully watched for symptoms indicating suppuration, when he would operate, not for diagnosis, but to give relief. Having exhausted other methods of diagnosis, he agreed with Dr. Johnston that, if the patient's life depended upon it, we should open the abdomen. He believed that in intestinal obstruction the abdomen should be opened, and that many lives had been lost by want of courage on the part of the surgeon. There was no question as to the duty of the surgeon in the case of gunshot wounds of the intestines.

DR. CHARLES T. PARKES, of Chicago, thought that the paper insisted upon the necessity of exhausting all other methods of diagnosis before resorting to laparotomy. In regard to the size of the incision, he thought that made very little difference so far as the final recovery was concerned, but, where the incision extended above the umbilicus, recovery was slower, and attended with more inconvenience. In the cases which he had seen where a post-mortem followed, there was no evidence that the abdominal incision had anything to do with the fatal issue. In regard to the operation in cases of intestinal obstruction where the exhaustion was extreme, several years ago he was called to see a case of nine days' standing. The patient was in a state of extreme collapse. He was anæsthetized and the abdomen was opened. A small cyst was felt immediately beneath the fingers. Under slight pressure it ruptured, and a quantity of offensive pus escaped into the abdominal cavity. This patient recovered. In such a case the best diagnostic skill could not determine the cause of the obstruction. In the case of a child 18 months of age, in which the operation was declined, the post-mortem revealed intussusception of the small intestine, which was without adhesions, and could readily have been overcome. He thought the abdominal opening should be made in the median line. In regard to closure of the wound, the simple suture passing through all the tissues had been followed by such good results that he thought we need use no other. Where there was much distention of the intestine he considered the method by opening the bowel the best. He had used the exploratory needle on several occasions, but it was necessary to make a number of punctures. In two instances he had found extravasation of fæcal matter through these punctures.

DR. L. McLANE TIFFANY, of Baltimore, remarked that during the last year he had met with four cases of what he believed to be

intestinal obstruction. In all four laparotomy was proposed. Two patients refused, and both died. Two accepted, and one of these recovered. The one that died was a woman aged 73, in whom the obstruction had lasted seven days. The intestine was enormously distended, and in the examination ruptured with the escape of the gas. After this it was extremely easy to find the seat of constriction. He thought the shock would be less if the intestine was emptied. In regard to the time at which the operation should be performed, no positive rule could be laid down. It must depend upon the acumen of the physician who saw the case. He agreed with the reader as to the great value of laparotomy as a diagnostic operation. It was not possible for any human being to recognize through the abdominal walls the manifold conditions of the organs present. In regard to pistol wounds of the abdomen, it frequently happened that the intestines escaped injury, and in these cases it was a question when the operation should be done. The opening of the abdomen would not, he thought, do much harm.

DR. J. F. THOMPSON, of Washington, wished to record two cases of laparotomy for the purpose of diagnosis. A woman, aged 35, had the history of an abdominal tumor lasting for several years. It presented the appearances of an ordinary ovarian tumor, with the exception that it had two sinuses communicating externally. After frequent examinations by various surgeons, it was decided to make an exploratory operation. One sinus was traced back to the peritoneum without reaching any satisfactory explanation of the tumor. The peritoneum was then opened and the finger introduced, but no tumor in the cavity could be felt. Toward the abdominal wall a mass, apparently imbedded in the tissues, could be distinguished. The wound was closed, and the patient recovered from the operation. She subsequently died, and the post-mortem showed that the tumor was an enlarged spleen, which had fallen down below the umbilicus and become attached to the abdominal wall.

The second case was one of carcinoma, involving the transverse colon, running directly through the mass. There was also an attachment of the growth to the liver. The abdomen was closed; the patient recovered from the operation, and was still living.

DR. W. H. CARMALT, of New Haven, said that, some time ago, he was requested to operate in a case of intestinal obstruction, but the collapse was so great he thought that

it would not be proper to do so. Within thirty-six hours the patient died. The post-mortem showed that the obstruction was due to a band of adhesion. If the operation had been performed early, the patient might have recovered. He considered it important to relate unsuccessful as well as successful cases.

DR. JOHNSTON, in closing the discussion, said there was a certain amount of hesitancy on the part of surgeons in regard to operating in cases of abdominal injury, on account of the people and on account of juries. To overcome these objections, it was necessary to educate the public to the true state of affairs. In cases where the bowel was opened, laparotomy led us to the seat of disease, and, if anything could be done, we were then able to do it.

#### CALOMEL AS A DIURETIC.

The action of calomel in causing diuresis in morbid conditions with dropsy is not generally recognized. In health, indeed, it may be said that the drug has no such action. DR. JENDRÁSSIC has found in cases of cardiac dropsy that calomel in appropriate doses causes well-marked diuresis, a "sort of diabetes insipidus," by which the results of want of cardiac compensation, dropsy, and œdema are dissipated. The effect comes on within twenty-four hours,  $1\frac{1}{2}$  grains of the drug being given three to five times a day. No diarrhœa is usually produced; but in some cases it had to be prevented by the administration of laudanum. Salivation and stomatitis were obviated by the prescription of a chlorate of potassium gargle from the first. The result in all cases in which the treatment was adopted was beneficial, no unfavorable depressing symptoms being noticed.—*British Med. Journ.*, February 13, 1886.

#### BACTERIAL PATHOLOGY.

With the conviction that a little humorous dessert will contribute to the digestion of the numerous therapeutic dishes served to our readers by the GAZETTE, we present to them some choice morsels picked from DR. NORDAU's interesting Parisian epistle to our Viennese contemporary, the *Wiener Med. Wochenschrift*, No. 8, 1886:

"The last of the valiant and dreaded enemies has surrendered. Stricker has hoisted the white flag and entered the camp of the microbio-pathologists with flying colors. He was one of those who had fought most bit-

terly and more persistently against the new faith, objection to which is at the present day only excusable in the man born blind, for he alone is not open to the *ante-oculos* demonstration of the microscope, the test-tube, and the pure-culture. But lo! there is still one pagan knight who is not to be converted, not to be conquered. Boldly and proudly he upholds the banner of the humoral (or is humorous now the proper adjective?) pathology. Not he that fears the impinging phalanges of the bacilli, shrinks before the spirillæ pickets, or loses his sang-froid at the approach of swarming spirochetæ. This knight *sans peur et sans reproche* is Peter, Prof. Peter, of the Faculty of Paris. Like Horatius Cocles, he fights alone against an army. Maybe, however, he only wishes to carry out Victor Hugo's heroic words: 'Et s'il n'en reste qu'un, je serai lui-là!'—And if but one is to remain, it shall be I. We all know of the reverend Pastor Knack, who bravely called Copernicus a liar, and defended the rotation of the sun around the earth. Knack's death was a hard blow to the humorous papers, still Peter is alive, that is some substitution. Peter's opening lecture of the last winter course, before the crowded auditorium, will remain forever memorable in the annals of medicine. Though it was full of *chic* and Attic salt, it cannot be said to have been seasoned properly, for the carnival was not to commence for some months yet."

We regret that our valuable space cannot be more exhaustively devoted to the amusement of our readers; a brief abstract of some few passages of Peter's lecture, which, intending to ridicule Koch, Pasteur, and Lustgarten, the discoverer of the syphilis-bacilli, ridiculed actually Peter alone, is all we can give:

"The bacillus discovered by the 'Berliner Koch' (why not the Prussian Cook?), and about which so much 'fuss' is made, has no diagnostic value, as it is found in tuberculosis, syphilis, leprosy, and even the preputial smegma of healthy persons. True, there are some trivial differences in these bacilli as to form and coloring matters, but what does that signify, as bacteriologists admit themselves that morphological differences play no essential rôle in the determination of the nature of a bacillus.

"What deplorable therapeutic results are there not ensuing from the views of the microbio-pathologists! They separate externally the tubercular subjects, and internally they give them alleged bacillus-killing drugs,

such as creasote, carbolic acid, and heaven knows what other dirt. ('Et on ne sait quelles saletés.') I shall not cease to fight with word and letter against this mental aberration which confuses the brain of profession and laity alike."

No wonder that the impulsive youth from the quartier Latin brought a thundering ovation to their enlightened and courageous teacher, who had thus disproven and conquered definitely the "Berliner Koch."

In conclusion, we have yet to allude to the nonsensical tribute paid to Peter by the *Evénement* (a Paris newspaper), which brought the picture of Peter in the rôle of George the Dragon-killer, and proclaimed at the termination of an article exornated with the usual Gallic *élan* and prestige, "And so has the common sense of the Frenchman again annihilated a chimerical product of German brains."

#### MORPHINE IN THE TREATMENT OF CONVULSIONS OF INFANTS.

DR. GEORGE T. FANNING, of Stony Brook, N. Y., reports in *The Medical Record* (April 24, 1886) the two following cases of convulsions in infants, in which morphine was given with ultimate good results. The first case was that of a girl, 2 years of age, who, when first seen, had been in rigid convulsions for about two hours. Potassium bromide and belladonna were given at short intervals for nearly three hours without relief, when it was determined to try morphine, and a dose of  $\frac{1}{16}$ th of a grain was accordingly given. In about half an hour the convulsions stopped, and the child stopped breathing at the same time. Artificial respiration was at once begun, and kept up for nearly an hour, at the end of which time natural breathing began again. The second case occurred in a boy,  $2\frac{1}{2}$  years old. Supposing the convulsions to be due to intestinal irritation, Dr. Fanning ordered an emetic and an enema, and gave chloroform to relax spasm. The convulsions ceased, and the writer went away, but was recalled in about an hour, the messenger stating that the child was worse than ever. He was found in a very rigid condition, with one pupil widely dilated and the other contracted. After an unsuccessful trial of chloroform,  $\frac{1}{16}$ th of a grain of morphine was given hypodermically, and in an hour  $\frac{1}{16}$ th of a grain more. The pupils both became contracted, the breathing was slow and stertorous, but the convulsions continued on one side. The chloroform inhala-

tions were continued for about two hours, when improvement occurred very slowly, and the child finally recovered.

#### A CASE OF COMPULSORY AND EXCLUSIVE BACKWARD MOVEMENT.

In *La Rivista Clinica* of June, 1885, DR. MAZOTTI reports the following rare case: An alcoholic, 66 years of age, was admitted into the hospital of Bologna for the treatment of scurvy. After his recovery from this affection, it was found that, in spite of the greatest efforts, he could only walk backward, and that after that he had to turn around his own axis. These movements, of course, constantly imperilled his life. He soon succumbed to pneumonia, and the examination of the brain showed an atheromatous condition of the vessels at the base. We wonder that the inspection of the spinal cord was omitted, which might have given some clue for these peculiar symptoms.

#### A CLASSICAL REMEDY FOR HICCOUGH.

DR. A. G. GIBSON calls attention in the *Edinburgh Med. Journ.*, April, 1886, to the old Hippocratic aphorism, "Sneezing occurring after hiccough removes the hiccough," and suggests, in cases of hiccough, the production of sneezing by tickling the nostrils, and he tells us that he has in this way been very successful in the arresting of this disagreeable affection. Hiccough, as well as sneezing, is one of the specially modified respiratory movements, and it is quite in accordance with what we know of the transference of nervous action, that the spasmodic contractions of the diaphragm should cease on the induction of the explosive expirations which constitute the acts of sneezing. There is one point, however, which deserves special mention. It is not necessary that the stimulus applied to the nose be followed by sneezing. The application of a gentle irritant to the nasal mucous membrane may be quite enough to put a stop to the hiccough, by diverting the nervous energy into other channels, although it may not be of sufficient power to induce sneezing.

#### A CASE OF CHROMIDROSIS, OR CHROMOCRINIA.

DR. FÉRÉOL communicates to the *Bull. de l'Acad. de Méd.*, 1885, No. 33, the case of a

hysterical young girl, who, at times of nervous excitement, presented a peculiar blue coloration of the under eyelids. There was no perspiration observable during the appearance of this phenomenon. The blue color could be readily removed by vigorous rubbing with a cloth, but grew more intense whenever the girl's attention was directed to her condition. In the axilla and over the sternum FÉRÉOL likewise occasionally noted this coloration. Examined microscopically the fragments of the pigment presented an appearance similar to the particles obtained by breaking up dried Canada balsam. The dried epidermic cells contained besides numerous granules of a bluish coloration.

#### THE EMPLOYMENT OF LACTIC ACID AS A CAUSTIC.

In the *Centralblatt für Chirurgie*, No. 12, 1885, Prof. Mosetig made the following astonishing announcement, "Acidum lacticum is a means of destroying morbid tissues, and distinguishes itself from all other hitherto known and employed caustics by sparing the healthy tissues."

It is, however, a well-known fact that all caustics destroy far more easily morbid than healthy tissues, and besides, the mentioned property of lactic acid is now disproven by the experience and publication of DRs. SPITZER and HERMANN, of Vienna, in the *Wiener Med. Blätter* of February 25, 1886.

These observers publish eight cases of lupus and epithelioma treated in the Allgemeines Krankenhaus in Vienna with concentrated lactic acid as proposed by Mosetig, and state their conclusion as follows:

1. The pain produced by the cauterization with lactic acid is at least as great as that caused by any other caustic.
2. The patients prefer invariably any caustic to lactic acid.
3. The action of lactic acid resembles that of other caustics, but is less energetic.
4. Healthy tissues are not spared any more by this than by any other caustic.
5. Lactic acid has to be employed for a much longer time than chloride of zinc and other energetic caustics.

In this connection we would call attention to the reports published in recent numbers of the GAZETTE where a large number of authorities were quoted as claiming most favorable results and confirming the statements of Mosetig-Moorhof in all particulars.

### AN ADDRESS ON EVOLUTION AND THE PATHOLOGICAL IMPORTANCE OF LOWER FORMS OF LIFE.\*

BY PROF. JOS. LEIDY.

GENTLEMEN:—I open my topic with an asseveration from the "Cosmic Philosophy" of that clear thinker, John Fiske, of Cambridge, "There is a Power to which no limit in time or space is conceivable, and all phenomena are but manifestations of that one

eternal and infinite power." It is this Power which is everywhere recognized as God, whose existence is proclaimed as the Supreme Truth alike by science and religion.

The genesis or original production of life is directly attributed to God, but the manner of its creation has always been and still remains a mystery. With the introduction on earth of a primitive form, or kind of living being, science is prepared to explain the subsequent production of all others, which, from the remotest period through successive ages down to the present time, have exhibited an infinite number of kinds of the most variable degrees of complexity, culminating in man and his contemporaries. The explanation is found in the doctrine of the evolution of life,

\* Delivered before the Graduating Class of the Medical Department of the University of Pennsylvania, May 1, 1886.

which is in accordance with the general law of evolution as propounded by that greatest of philosophers, Herbert Spencer. This general law, like that of gravitation, appears to apply to everything, and as the planetary system seems to have been evolved from ancestral nebulae, so all existing forms of life appear to have been evolved from organic dust, as first clearly set forth by that profound naturalist, Charles Darwin, who has recently left us, we may hope, for a still higher evolution.

According to the doctrine of the evolution of life, living beings have been derived from one another, the most complex and highest forms of plants and animals being the slowly modified descendants of less complex plants and animals, while these were the slowly modified descendants of still less complex forms, and so on until we go back to the earliest and simplest plants and animals.

The agencies by which the process of evolution is carried into effect are of the kind we daily observe in operation around us, as the incessant individual variation in plants and animals, their adaptation to environing conditions, and the hereditary transmission of acquired individual peculiarities.

The prevailing hypothesis of the origin of living creatures in all time, and still maintained by the greater but generally less informed and less thoughtful portion of society, is that each and every species of plant and animal was a special or direct creative act of the Creator. Thus, in illustration, it is considered that each and every species of oak and pine, of fish and bird, was a direct act by which it appeared in space independently of any pre-existing form. Those adopting the law of evolution see in all races of men one brotherhood, while those holding the doctrine of special creations, like the late Prof. Agassiz, are driven to the necessity of regarding each race as a distinct and separate creation.

The first revelation of the law of the evolution of life startled people from a revery. The doctrine for a time was accepted by few, and even reluctantly or with qualification by some of these, but generally it was rejected, pronounced incredible and absurd, and frequently became the subject of ridicule. Many, without reflection, made their feelings an objection to the theory; and even a distinguished professor of the Jardin des Plantes, of Paris, in a public lecture, thought he was using a powerful argument against it when he contemptuously stated that neither he nor his

audience wanted an orang for their grandparent.

The reception of new theories, or systems intended to convey general truths, has always been the same, and men never seem to be prepared for any unusual disturbance in the habit of thought. When Newton announced the law of gravitation, people objected to it, for they regarded it as a denial of God's control of the movements of the universe; and when Franklin suggested the use of the lightning-rod, it was denounced as an impious attempt to deprive the Deity of his thunderbolts. Often, to be sure, hasty judgment leads to false theories, but should the theory be true, sooner or later, despite all obstacles, it is accepted and added to the common stock of knowledge.

Time for due consideration and reflection, together with many new observations and discoveries in biology bearing on the subject, tend more and more to confirm the theory of the evolution of life, and I believe the doctrine is now sustained by most distinguished naturalists, and is accepted by a large portion of the educated and thinking community.

While the special creation of living beings cannot be clearly realized in thought, the production of the most complex and highest forms from the lowest and simplest forms, through the slow accumulation of change upon change, and by slow divergences which result from the continual addition of differences to differences, is readily conceivable. In like manner, as we may observe improved and conspicuously marked varieties of useful plants and domestic animals derived from inferior stocks through appropriate management, we can see that under similar conditions the various species of animals and plants now existing may have been derived from nearly allied forms of the age immediately preceding the present age. In this manner, for example, we can comprehend how, by gradual modification, the living species of elephants are the descendants of the nearly allied extinct species; and how our domestic horse and ass are the successors of a three-toed ancestor which has ceased to exist. While such a view of the origin of animals appears probable and clear, it seems impossible to realize how they could come into existence from empty space.

Withal, the law of the general evolution of life is not so extraordinary as is commonly supposed, and is really no more wonderful than the special evolution we observe incessantly going on around us in the develop-

ment and growth of every individual plant and animal. The earliest manifest germ of each seed and egg is a single microscopic cell, from which in a little space of time is evolved each and every form of living being, including man himself. Surely, then, if a single, simple organic cell shall, in the course of a few days, months, or years, result in the production of a moss, an oak, a worm, a fish, or a man, there certainly can be no improbability that a like cell, in the course of untold ages, may have been the ancestor of all existing forms of living beings. The infinite and mysterious power of the Creator is alike manifest in the development of each and every seed and egg, in the evolution of each and every specific form of life, and in the original production of that primitive and lowly form from which all other forms have been derived.

In the production, growth, and development of living bodies, the ultimate chemical elements of structure are derived from the mineral kingdom, where they compose the earth, water, and atmosphere. Living bodies are, however, composed from complex combinations of these elements, which originate in a common material which does not pre-exist in the mineral kingdom. This common material, named protoplasm, is distinguished as the physical basis or substratum of organization. It is a complex definite compound of the gaseous elements of the air and water with the solid elements carbon and sulphur. I repeat that it is nowhere to be found in the mineral kingdom. The skill of the chemist has failed to produce it, and science knows no efficient cause for its production other than God.

The amount of protoplasm required in the construction of organic bodies is enormous, is incessantly consumed in the requirements of life and in the death of living bodies, and is as incessantly renewed. What is the source of all this protoplasm?

Science has discovered the fact that protoplasm is produced under the influence of the solar ray in the green plant, which manufactures it from inorganic elements, chiefly water, carbonic acid, and ammonia. The animal takes no part in its production, but, on the other hand, consumes it, and returns the inorganic elements to their original source. Every tiny chlorophyll ball is a laboratory for the production of protoplasm, starch, and other important organic materials, and thus it is that the bright green verdure of the earth, which so delights the eye, is the com-

mon source of the material which is the basis of all organization. Though the sun is distinguished as the source of life, it is only one factor in its production, and would be powerless to this effect without the green plant endowed with special attributes by its Creator. All green plants are immersed in their food, the air, water, and earth, and hence they are commonly fixed or rooted to their place of birth. Animals, powerless to produce the material of their composition, are endowed with locomotive power to enable them to apply to the fixed plant for their food, or to wage war and prey upon one another for the same purpose.

As the only direct source of protoplasm is the green plant, it necessarily follows that in the order of origin this must have preceded the animal, and if we admit the doctrine of the evolution of life, of the highest from the lowest forms, the simplest of green plants is the all-sufficient element for the production of all organic forms.

An ancient and still prevalent doctrine among naturalists, philosophers, and others, holds the theory that the beginning of life proceeded from the waters. The facts of science go to show that the green plant, which in its origin preceded the animal, finds the most favorable conditions for its life in a moist atmosphere and in bright sunlight. Few green plants grow in the ocean waters below one thousand feet, and none below double that depth. In the language of the Bible, after the waters were "gathered together" and the "dry land" appeared, *then* "the earth brought forth grass." This seems better to accord with the condition most favorable to the production, development, and continued evolution of life. At the boundary of the islands or continents, as they emerged from the waters, the earth was maintained in a moist condition by the proximity of the ocean, and there the influence of the sun was all that was required in the production of the material basis of life.

In accordance with the doctrine of the evolution of life and its known conditions, we may reasonably infer that the first living being was the simplest green plant, which also may continue to exist in its original primitive form in our day. The law of evolution does not imply the necessity of change or transformation of the primitive form. While the process may go on under a change of circumstances, and many of the new forms undergo transformation after transformation, advancing in complexity, and acquiring new

habits and capacities, others, from the first, or after more or less progress, may deteriorate, become degraded, or dwindle away and become extinct, while others, again, may retain their original form, or any subsequent one, through all future time.

As illustrations of advancement even to a highly complex organization, and a subsequent retention of the form without manifest change through successive ages, we may refer to the animal *lingula*, whose remains are found in the Lower Silurian rocks, composed of the sediments of the ocean, and estimated to have been deposited millions of years ago, but which yet lives, apparently unchanged, on our Atlantic shore to-day. Likewise, the roaches and the scorpions of our time have their recognized ancestors in the ancient coal-bearing rocks; and the fish *ceratodus*, originally made known to us by Prof. Agassiz, from remains in the Jurassic and Triassic rocks, has recently been found, living in the muddy streams of Queensland, Australia.

Among the almost endless variety of living forms now existing is there one which answers all the conditions required by the law of evolution, and which may be recognized as the first-born of creation and that from which all subsequent forms of life have sprung? I repeat that if a single, microscopic cell, the germ of the seed or egg, under the usual appropriate conditions, shall, in the course of a brief space of time, end in the development or production of an oak or a man, there is certainly no improbability that a similar cell may have in the course of ages resulted in the evolution of all existing forms of living bodies.

The first-born of creation, I conjecture, we may recognize in the tiny green plant described by botanists as the *protococcus viridis*. It grows all over the world in the presence of a certain amount of moisture, warmth, and sunlight; and under these conditions is everywhere observed in shaded places, appearing like a coat of green paint on the north side of tree trunks, rocks, walls, fences, pavements, and the earth. Each individual plant is a single microscopic, spherical cell, enclosing a mass of chlorophyll, and it incessantly and rapidly multiplies by growth and segmentation. Readily detached from its position in the dried state, it is scattered as dust by the winds, and, when deposited in favorable positions, it is instantly restored to activity, and again reproduces itself.

In this most humble of green plants—the *protococcus*—we have the original type of

life, if not actually the first-born of created beings. A simple plant, endowed with the same wonderful capabilities of every seed and egg, it has been the progenitor of all succeeding forms of life, both plant and animal, culminating in man. The suggestion that *protococcus* is the first-born of created life and the progenitor of all subsequent forms to the highest, will no doubt excite a smile of incredulity; but if we admit the law of evolution of life it cannot be disputed that it is the all-sufficient element in the process. To Raspail, the French chemist, it furnishes the cell with which, if he were supplied, he said he could build up the whole organic world. In the evolution of life, *protococcus* is the first manifest step which accords with the declaration that "God formed man of the dust of the ground." I may add that in this we may see an illustration that between Science and Religion there is no conflict. It is in the interpretation of facts rather than in the facts themselves that the difference chiefly consists. The shield is altogether of silver or altogether of gold, as it is viewed from the one stand-point or from the other, but, after all, it is the same shield.

In the course of the evolution of living beings, a multitude of inferior organisms have come into existence, which prey upon superior organisms, are more or less hurtful or destructive, and are the chief causes of disease, suffering, untimely death, and decay. In regard to these consequences, Mr. Spencer remarks, that "if, in the uniform working out of the process, there are evolved organisms of low types, which prey on those of higher types, the evils inflicted form but a deduction from the average benefits. The universal and necessary tendency towards supremacy and multiplication of the best, applying to the organic creation as a whole as well as to each species, is ever diminishing the damage done, tends ever to maintain these most superior organisms, which in one way or other escape the invasions of the inferior, and so tends to produce a type less liable to the invasions of the inferior. Thus, the evils accompanying evolution are ever being self-eliminated. Though there may arise the question, Why could they not have been avoided? there does not arise the question, Why were they deliberately inflicted? Whatever may be thought of them, it is clear that they do not imply gratuitous malevolence." (*Prin. Biol.*, i. 354.) Of the inferior organisms which are detrimental to the superior organisms are the numerous animal parasites of other animals,

generally belonging to the class of worms, and called entozoa, from their living within animals, or intestinal worms, from the usual position in which they are found. Frequent and distressing, and often fatal, as are parasitic animals, they are far exceeded in subtle character, and in dangerous and destructive qualities, by the fungi. These are familiarly known as mushrooms, toadstools, moulds, mildew, rust, smut, and rot, and are relegated by the biologist to the vegetable kingdom, though they greatly differ in appearance, habit, and capability from green plants. They neither feed in the same manner as the latter, nor are they direct manufacturers of the chief organic elements. They prey on dead or dying plants and animals and their products; they are the ghouls of the organic world,—thugs concealed in darkness, and ever on the alert to strangle the traveller. As bacteria, they constitute the most degraded forms of living beings, and at the same time are the most potent agents in the production of pestilence, death, and decay.

Until recently fermentation and putrefaction were considered to be due to the exposure of organic substances to the combined influence of moisture, warmth, and air, but it has now been determined that the direct agents in these processes are microscopic fungi floating in the atmosphere, and that they will not occur without the presence of these organisms. Ordinary fermentation, as in the production of beer, wine, and other spirituous liquors, is due to the growth and reproduction of the yeast-fungus, *saccharomyces*, which decomposes the sugar present in the vegetal juices and converts it into alcohol and carbonic acid. The souring of fermented products, and their further changes, are due in like manner to the presence of other fungi. The putrefaction of meats, with its attendant disagreeable odors, is caused by the bacterium *termo*, and does not take place when access of this fungus is prevented. The decay of wooden buildings and other structures of timber is ordinarily due to fungi, commonly known as "dry rot," and consisting of species of *merulius* and *polyporus*. The blights, mildews, smuts, and rusts which are such enemies to the agriculturist, destroying his grain, fruit, and other vegetal products, are all fungous parasites.

Most wonderful and frightful is the power for evil of these corsairs in the sea of life. Differing in well-marked and decidedly important characters from green plants on the one hand, and animals on the other hand,

they may be regarded as forming a third and distinct kingdom of organic bodies. Only lately we have learned of a new phase in their career in relation to green plants, not destructive as usual, but in habit reminding us of the system of slavery previously observed only with man and certain species of ants. The researches of botanists now make it appear that the group of plants named lichens, those dry, gray crusts and threads which grow on the dead bark of trees, old timbers, rocks, and otherwise sterile grounds, are parasitic fungi, which entrap green algæ, like *protococcus*, and hold them in their toils while they feed on the products of their labor, the enslaved algæ in the mean time pursuing their ordinary course, and multiplying, as formerly among our own kind did the slave families of men.

Aside from the too familiar fact that man and other animals are infested with entozoa which produce more or less inconvenience and distress, and frequently disease ending in death, it has been made obvious to us in our time that more serious and wide-spread diseases are due to fungous parasites. Indeed, it is now the prevailing idea that most if not all infectious and contagious diseases are of parasitic origin. Various forms of microscopic fungi, of the order of bacteria, exemplified by the genera *micrococcus* and *bacillus*, have been discovered to be constant attendants on such affections, and in many instances have been demonstrated to be the agents by which the diseases are conveyed.

Louis Pasteur, the renowned French chemist and skilful investigator, on whom the eyes of the whole world are now directed on account of the thoroughness and success of his researches into the causes and prevention of some of the gravest diseases which afflict our race, declares that it is in the power of man to completely sweep parasitic diseases from the face of the earth. Perhaps the declaration may be too strong, yet it seems that the demonstrated facts are already sufficient to make us hopeful that we are on the threshold of discovery, by which we shall be enabled to bring the agencies of these diseases so far under control as to render them of no greater detriment than the ordinary accidents to which we must always be more or less liable.

A few significant facts may be mentioned in evidence that our expectations and hopes are neither visionary nor even exaggerated.

Only fifty years ago nothing was positively known as to the manner in which man and inferior animals became infected with para-

sitic worms. While the conviction of many was that all forms of living things were derived from parents, as expressed in the axiom *omne vivum ex ovo*, others openly or tacitly admitted their existence as evidences of the hypothesis of spontaneous generation. Well do I remember the time when an able teacher expressed the opinion that a shred of fibrin or mucus under certain morbid conditions might be transformed into a tapeworm; and another considered that maceration in water was sufficient to convert a horse-hair into a hair-worm or gordius. Since then many able investigators have most indubitably proved the doctrine that all organic forms, the simplest as well as the most complex, originate alone from parents. We have learned that parasitic worms, like ordinary insects, flies, butterflies, and beetles, pass through entirely different forms in different stages of their life, and that the different stages are passed in different animals into which they gain access through the food and drink. With these discoveries we have also learned the sure method of controlling and preventing the invasion of parasitic worms. By the proper cooking of food and the boiling or filtration of drinking water any parasites which may be present are destroyed, or prevented from entering the person they would otherwise infect. Man, perhaps unintentionally, has been freer from parasitic worms than most other animals, from the peculiar habit of using fire in the preparation of food, though he is often yet too careless in the employment of this agent, and thus frequently becomes the host of disagreeable or dangerous guests introduced through half-cooked meats.

I recall to mind an occasion upwards of forty years ago, while I was a student assisting my preceptor, Dr. Goddard, then demonstrator of anatomy in the University, and professor to Prof. Horner. We were making preparation for a lecture on the muscles, when Dr. Goddard, who was endowed with quick perception and sharp vision, observed an appearance in the flesh which led him to examine it with the microscope. In it he found a number of minute, coiled worms, to which he called the attention of Prof. Horner. The parasite had been discovered a short time previously by the English surgeon, Sir James Paget, and was described by Prof. Owen, with the name of *trichina spiralis*. Several years later I found the same parasite in pork. Then, and for some time subsequently, no significance was attached to the occurrence of *trichina* as a parasite, and if you will refer to

any medical dictionary published twenty-five years ago, you will find the worm mentioned, but no intimation of its relation to a grave disease which has since been recognized, but was then not even suspected. Now we are well informed of the parasitic affection trichinosis, caused by *trichina*, introduced into our body in pork, a meat which was declared to be unfit for food, thousands of years ago, by the great law-giver Moses. While *trichina* has been dealing death and destruction to our kind from the most remote times, until recently its existence was unknown, but having discovered it, we are now able to prevent its effects. As an example of its dangerous character, in a recent statistical account of trichinosis in Saxony, we read that in fifteen years, from 1860 to 1875, there were 39 epidemics of the affection, and 1267 cases with 19 deaths. We now have the *trichina* completely under control, and no one need run the risk of infection. By thoroughly cooking pork any parasites that may be present will be destroyed, and thus prevented from doing injury, and it may be added that by the process of cooking the pig ceases to be unclean food. The relation of such facts need and should not prejudice you against the use of pork as food, for all animals employed for the same purpose are likewise liable to be infected; but the cardinal rule should be observed that all meats, or such especially as have been recognized or are suspected to be liable to harbor troublesome or dangerous parasites, shall be cooked, by which process the parasites are rendered innocuous. Fire is the great purifier of food and water, and if it could be as readily applied to the air we breathe, we would in a great measure be able to get rid of all parasitic affections.

After the researches of Schwann and Pasteur had clearly proved that bacteria were the cause of putrefaction, Joseph Lister, the distinguished English surgeon, was led to regard the same organisms, introduced into wounds, as the cause of mortification, which so often defeats the object of the most skilful operator, and frequently destroys the patient. In this view he devised means for preventing the access or destroying these destructive organisms, and thus established that antiseptic system of surgery which is, as remarked by John Tyndale, one of the greatest and most beneficial achievements of our age.

In 1853 the silk-culture of France in value was estimated at twenty-five million dollars, but, as the result of a malady which affected the silk-worm, in two years afterwards fell

to five million dollars. Pasteur, having been requested by the Minister of Agriculture to undertake the investigation of the disease, which is called pebrine, determined it to be due to an exceedingly minute fungus parasite, a species of micrococcus. He proved that the germ might be present in the worm and in the egg and yet elude the search of the microscope. In the moth the fungus reaches a degree of development so distinct as to render its detection inevitable. From healthy moths, healthy eggs were sure to spring, and from these vigorous worms; and thus, by making the proper selection, the problem of restoring to France its former prosperity in silk husbandry was established.

In his researches on pebrine, Pasteur inquired how the disease was spread, and pursued the inquiry in the only manner that was open to him. He infected healthy worms, by smearing mulberry-leaves, their food, with material containing the fungus. He also infected them by inoculation, showing how they infected one another by scratches of their claws. Bringing together healthy and diseased worms, the healthy ones, like their smitten companions, soon sickened and died. He produced infection at a distance by wafting the fungus dust through the air. All the modes by which infectious diseases may be spread among human beings were thus illustrated. Here, I may add, we have also an illustration of the benefit that is to be derived from judicious experiments on living animals. Admitting that it was for the moment cruel to treat the healthy silk-worms in this fashion, it is clear that Pasteur's investigations swept a deadly epidemic from the soil of France, and for the units slain during the experiments millions have been preserved.

Splenic fever, or anthrax, an extremely fatal affection of cattle, was determined by the celebrated German physician, Dr. R. Koch, to be due to a bacterial parasite, the bacillus anthracis. Pasteur being led to investigate this disease has also discovered the means of preventing it. This is done by inoculating the animals liable to infection with a liquid containing the bacillus, which, by a process of treatment, has lost its virulence, and yet enables the animals inoculated to effectually resist the attacks of its more potent parent.

Hog and chicken cholera, equally destructive to the animals affected, have also been ascertained to be caused by similar bacterial parasites, and are now successfully treated in the same manner.

A micrococcus is the constant associate and cause of smallpox, and, as is well known, this dreadful disease has for a long time been in a great measure prevented by vaccination. In this treatment the same parasitic organism renders powerless the venom of its parent. Last, and not least, we now receive daily notices that that fearful malady, hydrophobia, also reputed to be caused by a bacterial parasite, has been brought under control by the great Pasteur.

Gentlemen, those of you who have chosen the responsible calling of the physician, and are now each of you, by title, doctor in medicine, we, your teachers, this day bear witness, before the trustees of the University and our fellow-citizens here assembled, that you are duly qualified to enter on the duties thereto belonging. By this calling you engage to take charge of the health of the community, to treat diseases and remedy accidents, or alleviate their pain and distress, and to save your fellows from untimely death. For this you are to expect and should receive due compensation for your services, or, in other words, you will practise your profession as a livelihood. Bear in mind, however, that it is not for this alone you are to labor, for the principles of the medical profession require you to do all in your power to promote the general health of society, even though there be no expectation of return other than that which arises in the common welfare. To the extent of your ability you should also exert yourself in the investigation of diseases with the view of preventing them. To no profession so much as ours does the altruistic sentiment apply, "Love thy neighbor as thyself;" and it is with a feeling of pride that I express the belief that no profession more than ours lives up to this precept, for no body of men are more self-sacrificing for the good of others than are physicians. Statistics show that the war against disease is attended with no trifling risks, and that those who fight this battle are exposed to chances of death above those incurred by nearly all their fellows. In the conviction that you are prepared to assume the duties and responsibilities of the medical profession, I would urge you to emulate its great spirits, its zealous workers, and its earnest searchers after truth and the common good of mankind.

It has mainly been under the advice and guidance of the medical profession that governments, societies, and benevolent citizens have established and supported hospitals and other asylums for the sick. Still further to

promote the health and common welfare, I feel that it is incumbent on us to advise and urge our government to appoint and maintain a sufficient corps of the most able physicians and skilful observers and experimenters, whose function it shall be to investigate all the causes of epidemic, contagious, and infectious diseases which affect man, domestic animals, and useful plants, with the view of determining means for their destruction or for preventing their action. Something, to be sure, has already been done in this way, and with such conspicuously beneficial results that we are encouraged to further effort to the utmost in the same direction. Until recently almost nothing was done to ascertain the causes and mode of prevention of diseases, and it was and still is customary to await their attacks, and then depend on drugs to exorcise them. Posterity, I apprehend, will look back with wonder at our apparent apathy and neglect in awaiting the invasion of epidemics and at our faith and dependence on the fetiches of medicine to destroy them.

On this theme I would like to dwell and say more, but our time is short and I must forbear.

#### THE RED SULPHUR SPRINGS, MONROE COUNTY, WEST VIRGINIA.

BY HENRY B. MILLARD, M.D., A.M., NEW YORK.\*

I AM prompted by the perusal of an article on these springs, by Dr. L. B. Anderson, which appeared in the April number of the THERAPEUTIC GAZETTE, to add some opinions and experience of my own relative thereto. Medical hydrology is as yet, with us, in a very primitive stage, and I regard with interest all writings calculated to develop it, to elevate to its true position the "cure" by mineral waters, and to throw light upon the real character and value of our mineral springs, many of which are but imperfectly known and understood.

These springs according to the analysis of Dr. A. A. Hayes, late assayer and chemist of Massachusetts, belong to that class of waters known, according to the French classification, as sulphuretted calcic, the other forms of sulphur water being the sulphuretted sodique, the chloride and sulphuret of sodium, and the sulphuretted hydrogen. The waters of Aix-les-Bains, in Savoy, belong to the same class as the Red Sulphur Springs, and have much in

common with them. Enghien, near Paris, and Schinznach, Switzerland, may be also cited as good examples of this kind of waters. They are of special use in inveterate rheumatic affections with fibrinous ankylosis, in muscular rigidity, and in neuralgic and paralytic affections having a rheumatic origin. This class of sulphur waters is likely to be prejudicial in organic visceral affections, as cirrhosis of the kidneys or liver, or in rheumatic or neuralgic conditions characterized by the uric acid or gouty diathesis; this class of cases, when requiring sulphur water, being more likely to be helped by a chloride and sulphuret of sodium water, such as Aix-la-Chapelle, or a sulphuret sodium water, as Caunterets.

My principal object, however, in writing this article, is to call attention to the existence of a peculiar sulphur compound, combined with organic matter, retained in solution in the water, but made jelly-like by the air or acids. There are about seven grains of this substance to the gallon. According to Dr. Hays, "it seems to be an azotized base combined with sulphur, and so combined as to neutralize the distinctive characters of sulphur."

"No trace of uncombined sulphur can be found in its fresh state, and when I fermented it, hydro-sulphuric acid was the form it appeared in. I deem this a very important distinction in a medical point of view, and incline to the opinion that *all the sulphur in this compound is in a state fitted to be absorbed in the animal system*, as no other known solution of powder of sulphur is, excepting, perhaps, hydro-sulphuric acid.

"The chemical history of the sulphur compound shows that, like yeast, it has the power of inducing changes among the constituents of another body like those it is itself undergoing."

These unanalyzable organic compounds with sulphur are met with in all of the Pyrenean sulphuret of sodium waters, particularly in those of Barèges, where it is known as *barégine*, or *glairine*. According to Dr. Grimaud (*loc. citat.*), ex-medical inspector at Barèges, "its quantity is almost always in proportion to the quantity of sulphurous principles. It presents the aspect of a gelatiniform organic substance, held in solution in the mineral water, and gradually becoming, on exposure to the air, of a jelly-like consistence. It forms in the basins and conducting pipes gelatinous masses, unctuous to the touch, which become rapidly putrid in the air, producing algæ of a particular nature (*sulfa-*

\* Foreign Corresponding Member of the Société d'Hydrologie Médicale of Paris, etc.

raire). This *sulfaraire* is an organized, living being, a vegetable confervoid. Under the microscope it shows filaments of extreme tenuity,  $\frac{1}{100}$  of a millimetre. These filaments are so many cylindrical tubes containing semi-opaque, globular corpuscles. Barègine exists in considerable amount in the waters of Barèges. It is to this that is due the peculiar unctuous feeling that patients compare to velvet; it possesses typical sedative properties, whose full therapeutic value has yet to be known."

Next to Barèges, this substance is found most abundantly in the waters of Cauterets, Eaux-bonnes, and St. Sauveur.

Now the practical part of all this is, that we have, I believe, in the Red Sulphur Springs, a water equally valuable in throat and bronchial affections with the famous waters of Cauterets and Eaux-bonnes, as well as being of equal value in many rheumatic, cutaneous, and neuralgic disorders. The waters of Cauterets, especially, have been unrivalled in the relief of follicular pharyngitis, in affections of the bronchial mucous membrane, in chronic laryngeal affections, chronic catarrhs, etc. Many thousands resort to them yearly. As I passed a month there, I had many opportunities of observing the beneficial effects of the waters. A number of my patients, some of them eminent professional singers, suffering from chronic throat and laryngeal troubles, whom I have sent to Cauterets, have been greatly relieved or cured. Many of my patients suffering from dartrous affections of the skin, or from rheumatic ailments, have been greatly benefited there.

Several years ago, on endeavoring to find at home some springs to which I could send certain patients, suffering from affections of the throat, who would not go abroad, I observed, in consulting Dr. Walton's work on the mineral waters of the United States, the similarity of the waters in question with certain of the foreign springs, and concluded they should prove equally efficacious in the same class of cases. I recommended, in the summer of 1884, a young lady to try the Red Sulphur Springs. Her trouble was laryngitis and pharyngeal and nasal catarrh, with a good deal of bronchial catarrh. One summer at the springs effected more benefit than had been accomplished by two years of treatment. Another young lady, suffering from chronic bronchitis with profuse mucous exudation, was equally benefited. These are the only two cases that have come under my personal observation. Of the efficacy of these waters in

pulmonary troubles I am unable to speak. My familiarity with the effects of the waters of Cauterets, Eaux-bonnes, Aix-les-Bains, etc., and their similarity in many respects to these, leads me to believe that we should find in them, *so far* as the waters are concerned, the same benefit in affections of the respiratory mucous membranes, in pharyngeal and nasal catarrhs, in chronic rheumatism of a certain type, and in dartrous affections of the skin. I say, "so far as the waters are concerned;" the Pyrenean springs have the advantage of a high altitude, Barèges being four thousand and Cauterets more than three thousand feet above the sea-level, and consequently combine the very important therapeutic properties of pure mountain air (the Red Sulphur Springs have an elevation of only thirteen hundred feet), and all the foreign localities I have mentioned have the very great advantages of splendid bathing-houses, arrangements for treatment by atomization and inhalation, excellent hotels, salubrious situations, and, not least, medical men of scientific ability and great experience, who give the cases of patients careful attention and consideration.

At Barèges, a small town of one hundred houses, there are every season seven thousand patients; at Cauterets and at Aix nearly three times that number. At many of our mineral springs at home where I have sent patients, the medical care has been quite indifferent and insufficient, and not to be compared with the care which patients receive at similar resorts abroad. This state of things is perhaps to be expected until our springs are better known, and until the "cure" by mineral waters receives with us the same consideration that it receives abroad. The domain of treatment by mineral waters has a legitimate existence, and I hope it will be enlarged and regarded by us as of more importance in the future.

---

ON THE VALUE OF THE OIL OF EUCA-  
LYPTUS IN SOME MALARIAL  
AFFECTIONS.\*

---

BY J. H. MUSSER, M.D., PHILADELPHIA.

---

FROM time to time claims of a flattering character have been made by various clinicians for the antiperiodic virtues of the oil of eucalyptus. The high standing of the

---

\* Read before the Philadelphia County Medical Society, May 24, 1886.

authorities compels us to accept their statement unless we can disprove them by clinical research. The following notes aim to be a statement, as well defined as circumstances admit, of the experience of the writer in the use of this drug in malarial affections. They embody an account of its effects not only in true intermitting fever, but also in the modified forms of the disease which are so commonly observed in this city.

*Intermitting Fever.*—Care was taken to eliminate all forms of paroxysmal fever not of malarial origin. The cases selected for treatment, therefore, to make the diagnosis more certain, were of those which had had a previous history of ague, those which presented themselves for treatment during the season ripe with malaria, those which lived in pronounced malarious localities, and which presented the organic lesions of intermitting fever,—enlargement of the spleen and blood impoverishment.

Twenty-eight cases, selected in accordance with the above statement, were treated. Of the twenty-eight cases, nine were cured, ten not cured, five were relieved, but other drugs used in addition to eucalyptus, and five did not report a second time.

Tables I. and II. represent respectively the cases benefited, and the cases that were not relieved or cured. On them the type of the disease, its duration prior to treatment by eucalyptus, the length of time the case was under observation, the season the attack developed, the residence of the patient, and some remarks are detailed.

*Analysis of Table I.*—Number of cases, nine. Type: Quotidian, one; tertian, five; quartan, one; irregular, two. Acute attack (under six months), five; chronic intermitting, four. Length of time under observation, ten days to six months. All the attacks developed in the usual malarial season. Seven of the persons resided in a positively well-known malarial locality.

It is a misfortune that some of the cases were under observation so short a time. It is fair to presume Cases Nos. 1 and 2 (acute attack, children) were cured. They were under observation only ten days, but lived so near the hospital they would certainly have returned had a relapse occurred. Case 7 returned three months afterwards for another complaint, and Case 8 returned six months subsequently for more of the medicine that cured her before. The remaining cases were from eleven days to three months under observation. At the risk of wearying you the

abstract of Case 5 will be given. It was one of the most striking of the cases, and the gratitude exhibited by the patient was impressive to the clinical class in the dispensary. The patient was a female, æt. 30, who resided in a malarious locality. She had been confined one year previous to her visit. In the second week of her convalescence a tertian intermittent developed. It had continued ever since then unless the patient was under the profound influence of cinchona. Her spleen was enlarged. She was ordered ten drops of the oil of eucalyptus four times daily. The treatment was persisted in. She remained under observation two months without any recurrence of the malarial symptoms. It is to be regretted no note was made of the spleen some time after treatment had begun.

Reference to the table will show that three of the cases had been treated with quinine, and that relapses occurred, subsequently controlled by the oil. "Cured" must not be used in a final or absolute sense, however. From the fact that sometimes any remedy will beneficially influence an ague, especially if a purgative or some dyspeptic elixir be given conjointly, we cannot be imperious in our sanction of the value of a drug. Likewise an attack of intermittent will cease of its own accord, especially if certain extraneous conditions, as a bad state of the weather, or relief from mental strain, or what not, be removed; such an attack may recur, when unfavorable conditions arise again. It cannot be said in any of the above cases that relapses did not occur, while they are noted to have recurred in two instances.

It is proper to state that to all the cases in the table a mercurial and saline was exhibited, with the exception of Cases 1 and 2.

But little need be said of Table II., representing the series unrelieved by eucalyptus. One was quotidian, seven tertian, and two irregular in type. Six of the cases were chronic, three acute, and one unknown. Four of the chronic cases continued to live in the malarial localities; two removed therefrom. The cases were under treatment but a short time. As soon as the drug was seen not to control the fever, other remedies were resorted to. Possibly, had the drug been continued for a longer time, or the dose increased in size or frequency, a different result might have been attained.

In addition to cases of true intermitting fever, the oil of eucalyptus was administered to a class of cases, constantly brought to our notice, which present varied general symp-

toms, irregular febrile invasions, gastro-intestinal disorder, and neuralgias, but which show a decided periodicity. Care was used in the selection of these cases also, and the same conditions required as in intermitting fever, and in addition thereto the presence of the periodical element, which, however, is often misleading, was insisted upon. The cases which are arrayed in Tables III. and IV. are instances in which we would without hesitation give quinine and its congeners. It is with considerable misgiving, however, that we report them, knowing so well the doubts that can be placed about each case.

Forty-four cases in all were thus selected. Twenty-six cases did not report for treatment a second time, and hence will have to be excluded. It is fair to presume, however, that some were benefited, for after the lapse of six months or more a few returned for other affections, and said they had been benefited. Of the remaining eighteen cases, fourteen were relieved and four not relieved. The fourteen that were relieved were under observation from five days to one year. Eight of them were treated during a period less than twenty days; the remainder were under notice a long time for other disorders that developed subsequently to the malaria. A reasonable amount of doubt might be thrown around the eight cases, and therefore, after carefully selecting the cases, and including only those that had been under observation twenty days or more, six cases, or thirty-three and one-third per cent. of the entire number, were cured of their malarial affection. It is worthy of note that in the cases not benefited by eucalyptus the diagnosis was more doubtful than in any other cases.

The oil, which is quite distasteful, may be administered in capsules, in emulsion, or in glycerin. Most of my patients have taken it on a lump of sugar. Ten drops is usually administered to adults, three or four times daily. I am inclined to think small doses, three or five drops, repeated oftener, would be of more

service. In one patient an intolerable nausea was produced; in another, an attack of diarrhoea developed subsequent to the administration of the oil.

In spite of the scepticism that naturally surrounds this subject, we are forced to conclude that the oil of eucalyptus is of material value in malarial affections, and in cases where quinine is, on account of idiosyncrasy, inadmissible, the drug may be relied on in nearly one-third (thirty-three and one-seventh per cent.) of all the cases of true intermitting fever, and in fully one-third of all cases of vague malarial intermittent affections.

*Conclusions.*—From the above studies it will be seen,—

1. That the oil of eucalyptus is of decided value in about thirty-three and one-third per cent. of all cases of intermitting malarial fever.
2. That it has no specific value in any one type of the disease.\*
3. That the longer the duration of the disease, the less liable is it to do good.
4. That relapses are not prevented by it.†
5. That its influence on the spleen has not been demonstrated.
6. That a dose of ten drops four times daily has been a sufficient dose, but that five drops every three hours would be of greater value possibly.
7. That good results are not attained as quickly as by large doses of quinine, but that a good effect should be observed within five days at least.‡

\* It failed in one case of puerperal malarial fever; it was not tried in remittent or continuous malarial fevers.

† One of my private patients, who contracted intermittent fever in the South, and had very frequent relapses in the North, in spite of quinine, has not suffered a relapse since taking eucalyptus three years ago.

‡ Dr. Hunter Robb, of this city, writes me he contracted intermittent fever along the Delaware River, and has had frequent relapses, all of which have been controlled quickly and effectually by eucalyptus. He experiences the same physiological effects with eucalyptus as he does with quinine.

TABLE I.—*Cases of Intermittent Fever benefited by the Oil of Eucalyptus.*

Type.	Duration prior to treatment.	Length of time under observation.	Season attack developed.	Residence.	Remarks.
1. Quotidian.	3 weeks.	10 days.	Summer, 1883.	Malarious region.	Girl, æt. 10; treated with quinine first, with relapse; gtt. v every 3 hours.
2. Tertian.	1 week.	10 days.	Summer, 1883.	Malarious region.	Girl, æt. 12; sister of No. 1.
3. Quotidian at first, now quartan.	Several months.	16 days.	Fall, 1882.	.....	Male, æt. 23; relapses after quinine; gtt. xx t. d. caused nausea.
4. Tertian.	6 months.	15 days.	Fall, 1882.	.....	Male; gtt. xx t. d.
5. Tertian.	1 year.	2 months.	.....	Malarious region.	Female, æt. 30; followed confinement; quinine constantly prevented parox.; enlarged spleen.
6. Quotidian, then quartan, finally irregular.	4 months.	1 month.	Fall, 1883.	Malarious region.	Male, æt. 23; gtt. x t. d.; enlarged spleen.
7. Tertian.	4 years.	15 days.*	.....	Malarious region.	Female, æt. 24; gtt. x 4 times daily.
8. Tertian, then irregular.	Every fall for 3y'rs.	5 days.†	Autumn, 1880.	Boatman; malarious region.	Male, æt. 37; gtt. x t. d.
9. Tertian.	4 years.	11 days.	Spring, 1880.	Malarious region (N. 45th St., Philadelphia).	Female, 24; gtt. x t. d.

\* June 29 to August 15; reported October 30 cured.

† November 2, 1883, to November 7, 1883; returned next June for some medicine; did not report again.

TABLE II.—*Cases of Intermittent Fever not benefited by the Oil of Eucalyptus.*

Type.	Duration prior to treatment.	Length of time under observation.	Season attack developed.	Residence.	Remarks.
1. Irregular.	Several years.	42 days.	.....	.....	Eventually cured by quinine and arsenic; male, æt. 35.
2. Tertian.	3 years.	6 days.	.....	Malarious region.	Male, æt. 14; quinine after euc.; spleen enlarged; anæmic.
3. Quotidian.	.....	5 days.	Autumn, 1885.	Malarious region.	Male, æt. 35; quinine after euc.; spleen enlarged.
4. Tertian.	Several years.*	4 months.	.....	Malarious region (river).	Male, æt. 50; persistent use of euc. failed to check.
5. Irregular.	2 years.†	3 months.	.....	Malarious region; same residence as above; along low stream.	Female, æt. 48; euc. checks, but not as well as quinine.
6. Tertian.	6 years.	6 months.	.....	Acquired along Susquehanna.	Male, æt. 38; seemed to modify but not control.
7. Tertian.	10 days.	10 days.	Summer, 1883.	Malarious region.	Female, æt. 35; quinine afterwards.
8. Tertian.	6 weeks.	7 days.	Fall, 1883.	Contracted along Susquehanna.	Male; after 7 days' use of euc. resorted to quinine.
9. Tertian.	2 years.	24 days.	.....	.....	Female, æt. 24; relieved by Fowler's solu.
10. Tertian.	3 months.	7 days.	Fall, 1884.	Malarious region.	Male adult; euc. replaced by cinchona.

\* Every spring and fall.

† In wet seasons.

TABLE III.—*Cases of Vague Intermittent Malarial Affections benefited by the Oil of Eucalyptus.*

Type.	Duration prior to treatment.	Length of time under observation.	Season attack developed.	Residence.	Remarks.
1. Quotidian.	.....	11 days.	August.	23d and Callow-hill Sts. (labored in swamp).	Male, æt. 38; periodical headache, with dulness and stupor; "bruised" limbs; poor appetite; dyspepsia; diarrhoea; poor sleep; night-sweats.
2. Quotidian.	4 months.	5 days; reported again in 1 year.	June.	Camden, N. J.	Chills daily; quinine; relapse every 14 days; dyspepsia; regular bowels; euc. prevented relapse and improved digestion, etc.; male, æt. 33.
3. Tertian.	Some weeks.	14 days.	June.	Jenkintown, Pa.	Tired, aching, drowsy, headache every second day; dyspepsia; constipation; euc. gtt. x 4 times daily; female, æt. 28.
4. Quotidian.	5 days.	5 days.	July.	40th and Mount Vernon Sts., West Phila.	Chilly and feverish; dull, aching headache; dyspepsia; euc. 4 times daily; male, æt. 29.
5. Quotidian.	.....	30 days.	July.	15th and Brown Sts.	Dull headache periodical, with general symptoms; relieved by arsenic; relapse; euc. gtt. x t. d.; male, æt. 21.
6. Tertian.	3 weeks.	6 days.	August.	31st and Page Sts.	Coldness, followed by fever; headache; good appetite; constipation; euc. gtt. x; male, æt. 39.
7. Quotidian.	2 weeks.	8 days.	August.	29th and Alter Sts.	Chilliness, fever, and sweat at first; no appetite; bowels regular; feverish every day; drowsy, dull, general aching; euc. gtt. x t. d.; male, æt. 13.
8. Quotidian.	6 weeks.	6 days.	August.	32d and Sansom Sts.	Periodical neuralgia, and general pains and aching; dyspepsia; euc. gtt. v t. d.; female, æt. 16.
9. Quotidian.	4 months.	5 days.	August.	Chester, Pa.	Chill, fever, and sweat at first; now cold and feverish, with debility and dyspepsia; male, æt. 63; euc. gtt. x t. d.
10. Quotidian.	5 weeks.	20 days.	August.	34th and Race Sts.	Neuralgic headache after 4 P.M.; dyspepsia; general aching; female, æt. 24; euc. gtt. x t. d., and acid. phos. dil.
11. Quotidian.	.....	28 days.	August.	Longshoreman.	Evening headaches; dyspepsia; regular bowels; general aching; male, æt. 52; euc. gtt. x t. d.; headache cured, and then added acid. phos.
12. Quotidian.	.....	.....	September.	.....	Male, æt. 38; "dumb ague."
13. Quotidian.	Several months.	29 days.	June.	20th St. and Montgomery Ave.	Chilly sensations and fever; dyspepsia and constipation; reported "a new woman;" constipation not relieved; female, æt. 45; euc. gtt. x 4 times a day.
14. Quotidian.	.....	24 days.	July.	15th and Brown Sts.	At first tertian; now chilly every day, and at 4 P.M. headache; ravenous appetite; constipation; dyspepsia; male, æt. 21; improved; relapsed in a few months; euc. repeated; did not report second time.

ON THE MEDICINAL VIRTUES OF  
ICHTHYOL.

BY DR. JOSEPH SCHMIDT, BERLIN, GERMANY.

THE brief but favorable editorial remarks concerning ichthyol contained in the April issue of the THERAPEUTIC GAZETTE have been the inducement to present to the readers of this widely-circulating journal the following essay, with the view to introduce to the American practitioner a remedy which may be justly regarded as a welcome acquisition to our therapeutical treasures. The high and manifold remedial virtues inherent to ichthyol, according to the clinically established testimony of authoritative voices from the German profession, suffice to protect this new medicament from the ephemeral fate in which the majority of novel remedies deservedly perish. It is rather a singular fact that the numerous preparations of ichthyol, which have been exhibited and prized by German practitioners for the last three years, could remain practically almost unknown in America.

I now beg to submit an exposition of the most salient physical, chemical, and physiological features of ichthyol, and to add to the hitherto gathered results of its clinical trials some personal observations of its therapeutic value.

*Literature.*—The literature on ichthyol is necessarily scanty, as can be expected in view of the recentness of its introduction into therapeutics. Save some promiscuously scattered journalistic notes, the following treatises alone invite our interest :

1. Prof. Baumann and Dr. Schotten, in the *Monatschrift für Praktische Dermatologie*, 1883, Heft 9.
2. Dr. Unna, in the same journal, 1882, Nos. 11, 12 ; in the *Deutsche Medizinische Zeitung*, 1883, No. 17 ; in the *Sammlung Klinischer Vorträge*, Leipzig, 1885, No. 252, page 2287 ; and in the *Aerztliche Vereinsblatt für Deutschland*, 1885, No. 158.
3. Dr. Lorenz, in the *Deutsche Medizinische Wochenschrift*, 1885, No. 23, and in the *Deutsche Militärärztliche Wochenschrift*, 1885 (Mittler, Berlin).
4. Dr. Ackermann, in the *Correspondenzblätter des Allgemeinen Ärztlichen Vereins von Thüringen*, 1885, No. 8.
5. Prof. Binz, at the Fourth Congress of Internal Medicine in Wiesbaden, April 8 to 11, 1885.
6. Dr. v. Hebra, in *Die Krankhaften Veränderungen der Haut*, Vienna, 1883.

*Physico-Chemical Properties.*—Ichthyol, or fish-oil (*ἰχθυος*—*ōlēion*), was first prepared by Schröter, a chemist of Hamburg, and represents the distillation product of a peculiar bituminous sulphurous mineral obtained from the deposits of fossil fish. According to Baumann and Schotten (*loc. cit.*), ichthyol, or the ichthyosulphate of sodium, has the following composition :

Carbon.....	55.05 per cent.
Hydrogen.....	6.06 per cent.
Sulphur.....	15.27 per cent.
Sodium.....	7.78 per cent.
Oxygen.....	15.83 per cent.
	99.99 per cent.

Its chemical formula is  $C_{26}H_{36}S_2Na_2O_6$ .

Ichthyosulphate of sodium is obtained by the action of concentrated sulphuric acid upon the distillation product of the mineral and subsequent neutralization with sodium. The specimen at my disposal presents a tar-like appearance and odor, an alkaline reaction, and the consistency of vaseline. The drug is perfectly soluble in water, partly so in ether or alcohol, but readily soluble again in ether and alcohol combined ; with fats and vaseline it can be incorporated in every desired proportion.

Its sulphurous constituents belong partly to the sulpho group, and are partly attached to the carbon. As the sulpho acids exercise themselves little or no action on the animal organism, the therapeutic action of ichthyol must be referred to the sulphur attached to the carbon. Through the introduction of the sulpho group into a sulphur-containing oil, the latter is rendered both soluble and resorbable. This feature distinguishes ichthyol from other organic sulphurous compounds previously proposed as therapeutic agents. "Alongside of the considerable percentage of oxygen," says Unna, "the sulphurous constituents of ichthyol represent its essential and active principle."

"The extreme solubility of ichthyol," says Prof. Ziemssen, "enhances the practical value of the remedy."

The following preparations of ichthyol, obtained from Cordes, Hermann & Co., in Hamburg, were (with the exception of the two last) examined and employed by the author :

1. Ichthyosulphate of sodium, pure or diluted.\*
2. Ichthyol in an alcohol-etheral solution (five per cent.).

\* A potassium and an ammonium salt are likewise prepared from ichthyol.

3. Ichthyol cotton.
4. Ichthyol plaster.
5. Ichthyol soap.
6. Ichthyol vaseline.

The somewhat unpleasant odor and taste of the preparations intended for internal administration can be satisfactorily disguised by the addition of a few drops of alcohol in which equal parts of cumarine and vanilline are dissolved.

The physiological experiments hitherto instituted with ichthyol are too deficient to claim our attention, and give no clue to the therapeutic efficacy of the drug.

Baumann and Schotten determined experimentally the absolute innocuousness of ichthyol, and found that doses of a medium size produced in dogs no palpable physiological alteration, while larger doses (3 to 5 drachms) caused copious intestinal discharges, continuing for several days. We regret the absence of exact and thorough physiological researches in reference to ichthyol, and hope that this gap will be filled in the near future. It is thus in an exclusively empirical sense that we are led to appreciate the therapeutic effects of the remedy which we are to discuss at present.

For the sake of a convenient survey, I shall at first simply indicate the various therapeutic uses without further commentary.

#### A. External application :

1. In lesions, wounds, and diseases of the skin (eventually with a simultaneous internal administration).
2. In tumefaction of joints.
3. In muscular rheumatism and neuralgia.
4. In catarrhal affections of pharynx and larynx (gargles and atomization).
5. In toothache.

#### B. Internal administration :

1. In gout and rheumatism.
2. In catarrhal gastric affections.
3. In chronic constipation.

Unna, the distinguished dermatologist of Hamburg, has the merit of having first pointed out the great healing power of ichthyol in affections of the skin and its remarkably extensive applicability in the dermatological practice (Wiesbaden Congress, April 8 to 11, 1885). It would exceed the scope of this paper to dwell on the numerous and different published cases of skin-diseases as treated successfully with ichthyol by Unna. His experience in the treatment of lepra with ichthyol has been formulated by this author as follows :\*

1. The cure of lepra, even if existing for more than a year, can be effected in a comparatively short time by a systematic external and internal exhibition of reducing agents, especially of ichthyol.

2. The ichthyol salts are externally to be employed in a very concentrated form. Internally, ordinary doses (15 grains *pro die*) suffice. Being the only one of the suitable reducing remedies that may be taken internally *ad infinitum*, the ichthyol salts are of unequalled value in the lepra of internal affections (eyes, scrotum, liver, and lymphatic glands). Externally, they are indicated in weak constitutions, in presence of a very sensitive skin, in transitory or absolute contra-indications of stronger applications (chrysarobine, pyrogallol, and in the lesions of the integument produced by the latter).

3. Ichthyol is not only an external (though mild) antileprosum, but acts also by its peculiar alterative virtues when ingested by a leprous individual.

4. The prognosis of lepra must be regarded as more favorable than that of the syphilitic lesions, as far as relapses are concerned, for the remedy of lepra need not be suspended, like mercury and iodine, on account of eventual after-effects.

Küssner,† of Halle, regards as indications of ichthyol eczematata of every description (pruritus universalis, prurigo, and chronic and acute articular rheumatism). Prof. Binz, of Bonn, eulogized the preparations of ichthyol likewise at the Wiesbaden Congress. Unna (*Aerstl. Vereinsbl. f. Deutschland*, 1885, No. 158) emphasizes the healing power of ichthyol in the various forms of acne, complicated with rosacea, and in rosacea alone. We quote here the words of the dermatological authority : "If the substitution of sulphur by the preparations of ichthyol must be considered a progress already in acne, as ichthyol, unlike sulphur, never attacks the eyes, this substitution is still of greater importance in rosacea. The cure of this affection, previously laborious and doubtful, has been rendered rather easy and prompt by ichthyol. I give ichthyol internally in this affection, as follows :

R Ammon. sulphoichthyolici, fʒi-ii;

Aq. dest., fʒv. M.

S.—15-30-50 drops (gradually increased) in water morning and evening.

In another place of the quoted paper Unna says, "The internal use of ichthyol regulates the circulatory disturbances of organs, and is

\* Monatsh. f. Prakt. Dermatol. Ergänzungsheft, 1885.

† Wiesbaden Congress.

indicated in hyperæmia and swelling of the nasal and pharyngeal mucous membrane, hyperæmia and chronic inflammation of the conjunctiva, frost-bites on hands and feet, sensation of cold in the extremities, hemorrhoids, menstrual anomalies, and pains in loins and back caused by sanguineous stagnation in the pelvic organs. Ichthyol raises the working power of the digestive organs, regulates (without increasing) the movements of the bowels, and heals old gastro-intestinal catarrhs. Digitalis, when given for cardiac affections, is no contraindication for ichthyol."

(To be concluded in next issue.)

#### ALUMINIUM BRONZE IN MEDICINE AND DENTISTRY.

BY PROF. C. SAUER, BERLIN, GERMANY.\*

ALUMINIUM BRONZE, which I have utilized for the under layer of teeth-plates, is entirely free from injurious oxidation. For this purpose, and in teeth-straightening machines, it admits of easier manipulation than gold alloys or silver. I believe, therefore, that it might be of use in the manufacture of surgical instruments. Canulas, sounds, catheters, etc., might be made, and everything that is manufactured from silver. It is an alloy of 900 copper and 100 aluminium. It admits of almost as ready stamping and pressing as pure silver (which, next to pure gold, is the softest metal), and it has besides the elasticity of steel. In form of wire, aluminium bronze possesses a power of resisting tension approaching that of steel wire. These characteristics render the aluminium bronze capable of substitution in many cases for silver, and for silver and gold alloys. I have found the melting-point of the aluminium bronze to be higher than that of pure gold,—1000° C. It may, accordingly, be made red-hot without danger of melting, and manipulated with hard solder. I solder it with from 14- to 16-carat red gold, and such solder is more capable of resisting chemical influences than the silver solder, which contains zinc. 10 grms. of aluminium bronze, in the form of a lead plate, are worth 25 pfennige (6 cents), while 10 grms. of 12-carat silver, in the form of a lead plate, are worth 1 mark 50 pfennige (37 cents); 10 grms. 14-carat gold cost 19 marks (\$4.75). Aluminium

bronze is one-half lighter than 12-carat silver, and almost half the weight of 14-carat gold.

For testing how aluminium bronze is preserved in the mouth, I have employed the galvanic current. Pure aluminium, with other metals, in the presence of an acid or an alkali, yields a galvanic current. Years ago, in experiments with the mouth, I found that in a combination of aluminium with zinc the latter oxidizes. In manufacturing a combination of aluminium with gold alloy or platinum, under such circumstances, the aluminium, on the contrary, decomposes. In two cases in which it was possible for me to weigh pieces of aluminium bronze placed in the mouth, under the influence of a possible galvanic current, and the pieces not being cleaned, and therefore not mechanically worn, after the lapse of four weeks I noticed no loss of weight. For instance, with a piece weighing 16 grms. I have been able to discover only a loss of 0.008, and, besides, after first weighing the piece,† a screw was afterwards inserted, so a very slight mechanical loss of weight, therefore, took place. The aluminium bronze oxidizes only superficially in the mouth. There forms upon it a kind of patina, such as is formed in the wearing of plates of 14-, 16-, 18-, and even 20-carat gold. It admits of manufacture into spiral springs, plates, screws, canulas, etc., for surgical purposes. Even knives have been manufactured therefrom. A solution of corrosive sublimate of 1 to 1000 affects it superficially. For its disinfection carbolic acid is to be preferred, as it does not attack the aluminium bronze. Gold aluminium bronze acts similarly, but oxidizes to a greater extent, is softer, and not so elastic, and therefore is to be used as green gold or 20-carat gold is used.

#### LEGAL TENURE OF CEMETERY PROPERTY.

BY HENRY A. RILEY, ESQ., NEW YORK.

THE tenure of cemetery property is an important matter, as it concerns every one to know in whom exists the ownership of land in which is buried the remains of departed ones.

The question has assumed a new aspect in recent years, owing to the formation of the large public cemeteries. Prior to fifty years

\* Instructor of Dentistry at the Institute of Dentistry of the Royal University at Berlin.

† A bandage for fracture of the upper jaw, which was shown at the Surgical Congress in the mouth of the patient.

ago interments were almost universally made in grounds surrounding churches or in land belonging to some political community, such as a town or village. The ownership in England of the church building and the burying-ground surrounding it has been held to be in the rector of the parish, and he has exercised at times the most arbitrary exclusion of the bodies of persons whose friends wished to have buried in the ground made sacred by the use of centuries. While the ownership of the land has been held to be in the rector, the courts have also held that every member of the Church of England has the right of burial within the parish church-yard, and cannot be deprived of it. The cases of exclusion noticed have mainly been those of persons connected with Dissenting Churches, but who paid taxes for the support of the Established Church, and who desired interment beside the remains of members of their families who had been in communion with the Established Church. In this country the colonies had at the outset what often was practically an Established Church, yet the right of burial does not seem to have been refused to any one in the burial-grounds which were created and owned by the town or village, and yet the individual did not in many cases acquire personal ownership of a lot. There grew up as the country became older desires for a more certain tenure of cemetery property, and consequently cemeteries other than the common grounds of the town were sought. The churches set aside land surrounding them for the burial of their members and their families, private grounds belonging to a few families were formed, or a special piece of ground was consecrated on some hill-top or in some valley for the separate use of a single family. Last of all came the formation of large public cemeteries, organized under State laws or by legislative charter, which had no connection with any ecclesiastical organization, but were intended for the general public.

In addition to these public cemeteries, which have become so prominent in connection with burial, there are near many of the large cities cemeteries belonging to special denominations but open to the interment of any person belonging to those churches. Such are Calvary Cemetery, under the control of the Roman Catholic Church, and the Lutheran Cemetery, belonging to the church of that name, both of which are near the city of New York.

The principles of tenure in these various forms of cemetery property differ somewhat,

and many of the States have special statutes, which will be referred to in another article. In burial-grounds surrounding churches, which, in times gone by, was the general place of sepulture, the title was in the church organization as much as that of the church building itself. In many cases land was given to churches for the purpose of creating or enlarging burial-places. The church, which usually was not a corporation, but a voluntary association of persons holding similar ecclesiastical opinions, held the title as other voluntary associations are allowed to do under the laws of the various States, the fee being in the whole number of members. It is probable now that almost every State has laws permitting the formation of religious corporations, and such bodies would hold the title to burial-grounds, succeeding in the cases of long established churches to the title held originally by them as voluntary associations. In these burial-grounds lots were generally set aside for families, and often by written instruments, giving certain rights. Money was frequently received for such lots, and receipts given. Documents, in the nature of deeds, were passed in many cases, yet these often wanted some of the requirements of ordinary deeds, or were full of conditions, so that title in the common sense could not be again transferred. These documents were not usually recorded, and at the present time it is rare to place on record any transfer of cemetery property, such as individual lots, whether in church grounds or the large public cemeteries, such as Laurel Hill, Greenwood, or Mount Auburn.

This being, then, the usual custom about transferring rights from church organizations to individuals, it has become a very interesting question to know exactly how much of ownership was transferred to the individual by the payment of money and the setting aside of certain fixed spaces of ground. In general, it may be said that only the right of burial was transferred. The individual did not acquire and could not exercise the ordinary rights of ownership. He could not dispose of the lot for purposes other than burial, and this was true whether the document transferring to him a qualified ownership mentioned the restriction or not. The individual could, however, exercise some powers over the cemetery at large. The bodies of the dead could not be touched by any one for purposes of removal without the consent of the owner of the lot or the order of a court, and cemetery authorities them-

selves were in the same position as to removal of bodies. In this latter case, however, the statutes of the several States often prescribed a way for the legal removal of all of the bodies buried in a cemetery to a new location.

The law generally held that the individual owner had an easement in the land but not an unqualified ownership. This was equivalent to a right of continued and uninterrupted possession and occupation.

The right was similar to that by which a pew in a church was held when it was sold to an individual. In such cases the owner had no power to dispose of the few feet of ground on which his pew was resting in any way contrary to the regular purposes of church worship.

Even when it has been conceded that the individual did not have an unqualified fee in a burial lot, it has been sometimes claimed that the dedication by a church, or any other organization, of land for burial was so public and sacred that the land could never be used for any other purpose than burial, and that consequently the individual occupation, if not ownership, would be perpetual. But it is doubtful if there was ever any real basis for this claim in the common law. It has been held that the courts, even without special statutes, could, for good reason shown, direct the removal of bodies, and this in the face of passionate opposition on the part of lot-owners and relatives of the deceased. Such questions rarely arise now, as the States generally have specified a way by which the propriety of removal can be lawfully decided.

In the case of private cemeteries, for a small locality or community, the same general principles of ownership are to be applied.

In the case of burial-grounds containing only the bodies of a single family, ownership, it would seem, was in common, and descended to the heirs. The States have in many cases declared that grounds of this character could not be laid out within specified distances of neighboring houses.

In the case of the large public cemetery corporations the title is usually in the corporations and not in the individual lot-owners. Such cases are usually governed by the carefully-drawn regulations of the organizations themselves. Some do not grant a fee but only an easement, and some grant a fee but subject to restrictions. Reference will be made in another article to some of the principal cemeteries and their regulations.

In regard to restraints upon alienation, where the individual owners have some sort of a title,

it may be said that the courts will not permit the sale by one of several owners to strangers, and injunctions will be granted forbidding such transfers. This seems to be true under the common law, and in many States laws directly forbid any transfer whatever after bodies have been once interred in a lot, the title passing in such cases only to heirs by descent. It has been held that without a law on the subject it was not contrary to public policy to mortgage an individual lot. In New York, however, and other States all mortgages are now forbidden. Lots are exempt from sale under execution on debt.

#### VICARIOUS GENEROSITY.

A very good story as to a mode of repelling unwarranted claims on medical charity, which in some cases at least may prove successful and worthy of being repeated, is related in the *Brit. Med. Journ.*, March 20, 1886.

"A lady of quality," a peeress to wit, sent her butler to a well-known physician, a man who, were we at liberty to mention his name, would be generally recognized as one of the busiest men in London, with the request that the patient might be examined and prescribed for, gratuitously, of course. "My good-man," said the physician, "as you are my lady's butler, you are not a suitable person to be treated at the hospital where I see poor patients for nothing; in my own consulting-room, my time is too valuable; here is a guinea, go and see my junior colleague, Dr. —; he is not so busy as I am, and will be able to advise you for that fee." Her ladyship, it is interesting and instructive to learn, repaid the guinea next morning. The moral is plain. The profession as a whole does so much charitable work, that many people seem to expect that every member is to give his time and labor at any time and any place, and to any extent which may be most convenient to the patient or his friends. Quite a large enough proportion of the people who go to hospitals have no right to gratuitous advice, and it is asking rather too much of even the most patient and long-suffering to expect that a still more well-to-do class, too fastidious to go to hospitals, should be allowed to invade private consulting-rooms during the morning hours, which are dedicated to remunerative labor. No other profession has such claims made on it. If the butler had been in some legal difficulty, would the family lawyer have been expected to advise him gratis?

### RECENT PROGRESS IN SANITARY SCIENCE.

THE constantly-increasing demand in every community, that physicians should be not only, as in former ages of the world, healers of disease, but also preventers of derangements to health, in accordance with the laws of both public and personal hygiene, is manifested in numerous ways, and especially indicated by the reports of State boards of health, which accumulate with great rapidity upon our editorial table. Thanks to the deplorable outbreak of typhoid fever at Plymouth, Pa., our own State has at last joined the number of those in which systematic care for the health of citizens is imposed as a duty upon a governmental department, and at the present time Ohio is the only prominent member of the American Union in which an organized struggle against the causes of preventable disease and premature death, by an established State board of health, is neglected.

Among the highly important and as yet unsettled problems now demanding solution at the hands of sanitarians, is that of sewerage systems and sewage disposal, to the dis-

cussion of which a large part of the non-statistical section of the last Rhode Island report is devoted. The author of this able essay considers the questions involved especially as applicable to the needs of the city of Providence, and after an extended investigation of the methods of sewage disposal in England and on the continent of Europe, Mr. Grey, as city engineer, recommends the conduction of the sewage to a point below the city, when after treatment with chemical substances, which will precipitate the suspended matters, the clarified effluent is to be emptied into deep water, with which it will be carried out to sea. Mr. Grey recommends this process because he believes that the resulting purified liquid will be entirely harmless, and that, therefore, although this plan is less effectual than the mode by sewage irrigation as practised in Paris, yet it will be preferable in this instance on account of its smaller cost. The amount of town sewage from Providence is estimated at about three millions of gallons daily, and the expense of the additional sewers, tanks, and other apparatus, is calculated at nearly four millions of dollars. The sludge or precipitated material is to be compressed into a mass firm enough to admit of easily handling, and is believed to be valuable as a fertilizer, although no immediate income to the municipality from its sale as a manure is expected. At the present time it appears that all the precipitation methods are carried on at a loss to the town authorities employing them. The plans are very numerous, but those which have best stood the test of time are three in number, namely: 1st, the Coventry process, in which the sludge results from the addition of crude sulphate of alumina, salts of iron, and lime; 2d, the native guano, or A B C process, in which alum, blood, clay, with animal charcoal, are the precipitants; and, 3d, the lime method, in which milk of lime is employed. Of these the A B C device, the merits of which were very highly vaunted at first, has been generally abandoned, except in the town of Aylesbury, England. At Leeds, England, the lime process has been substituted for the A B C method, in which, although the resulting effluent is more thoroughly purified, less economy is secured than by that in which milk of lime is employed.

The establishment of works at Providence, in accordance with the carefully-considered suggestions of Mr. Grey and his assistant, Charles H. Swan, will doubtless be watched with great interest by American sanitarians, and the results which may be attained, like

those afforded by the experiment now going on in Memphis, upon the separate system of drainage, will be of great value to sanitary engineers generally, whether they lead to failure or success.

For several years past the efficiency of the Massachusetts Board of Health has been so unwisely crippled, in consequence of political influences, which decreed its union with the departments of lunacy and charity, that little good work has been accomplished, and the annual documents put forth under the name of reports have presented a lamentable contrast year after year to the earlier volumes, which formed a series of which even our modern Athens might be proud. The supplement to the report of this heterogeneous board for 1884, containing the papers on public health, displays, however, a creditable renewal of activity in the pursuit of sanitary science, which may perhaps be attributed to the encouraging prospect of a restoration to the hygienists of Massachusetts of independent organization.

Among the valuable essays presented in this volume is that of Prof. Edward S. Wood, M.D., on "Arsenic as a Domestic Poison," in which he endeavors to popularize a knowledge of the fact that many of the red, yellow, and brown wall-papers in common use are almost as dangerous as the bright green decorations which have been so frequently condemned by hygienists as to largely prevent their employment. This admirable article of Dr. Wood's is illustrated in the most practical manner possible by a series of thirty-six strips of wall-papers, calico and Turkey-red fabric, which, with a single exception, contain arsenic in quantities varying from about half a grain up to nearly fifty-six grains per square yard. None of the heavily arsenicated papers, such as were described in a report by Dr. Draper some years since (in one of which two hundred and sixty-three grains of arsenic per square yard were found), have been included in this instructive collection of poisonous wall decorations. The reason for their omission is given in the powerfully-suggestive circumstance that on the previous occasion, when such samples were used in illustration, their handling and folding by the bookbinders employed were found to give rise to extremely disagreeable effects,—that is to say, the usual symptoms of arsenical poisoning. It is worthy of note that the single specimen of wall-paper in Prof. Wood's series in which no arsenic could be detected was of a bright green color, showing that no necessity for the use of

Scheele's green and other arsenical pigments in the printing of wall-papers really exists.

Dr. Wood very properly directs attention to the fact that those among his samples called by dealers "glazed and plated papers" are the most dangerous, because they are so largely used by young children of kindergarten schools in the manufacture of the attractive but perilous little mats, covers, etc., in which the infant constructors take so much delight. Even when teachers of such embryonal educational establishments instruct the pupils not to place the brilliant strips of paper in their mouths, or even between the lips, there is no doubt that tiny particles of the deleterious pigment are frequently rubbed off upon the hands, and being conveyed to the mouth, and passing from thence to the stomach, give rise in numerous instances to otherwise unaccountable derangement of health. One of the green papers described, and actually used in kindergartens, was loaded with twice the fatal dose of arsenic for an adult upon every square foot. The green paper used in covering a small handbox, having three square feet of surface, which was examined by Dr. Wood, contained about one hundred grains of arsenic, and the same deleterious metal was found in alarming quantity in the papers employed in manufacturing theatre-, concert-, and car-tickets, playing-cards, and many other objects handled freely, and frequently without the smallest hesitation, in the daily occupations or the pleasures of civilized life.

Prominent among the Western State boards of health stands that of Illinois, holding the proud position of an eminent benefactor to the whole American people, through its efforts to elevate the standard of medical education and cut short the careers of medical quacks and charlatans upon our Continent. The practical efficiency of the stringent regulations adopted by the Illinois Health Board is proved by the fact, that whilst in 1880 there were but fourteen medical schools in the United States which required evidence of suitable preliminary education, and seventeen which gave some prominence to the study of hygiene, there were in 1885 one hundred and ten colleges insisting on the preliminary education requirement, and ninety-one in which preventive medicine was duly taught. Although, as Dr. Rauch, the energetic secretary of the Illinois Board of Health, remarks, some of this improvement is apparent only, the announcements being in a few instances intended chiefly as a means of securing wider

and more favorable advertisement of their institutions, yet deducting whatever allowance the most sceptical may demand on this account, there still remains a substantial gain for the present, and a still more brilliant promise for the future of medical education in America.

The peculiar excellence with which we believe every impartial reader, as he rises from a perusal of the last Michigan health report, must credit Dr. Henry B. Baker, its indefatigable author and secretary of the board, is the thoroughness with which accurate information on sanitary subjects is disseminated among the people of Michigan, fortunate enough to enjoy the official care of this active organization. Not only is an earnest effort made to faithfully discharge the duty of warning American citizens against the ordinary causes of disease, such as typhoid fever, diphtheria, and scarlatina; by the free distribution of brief essays or leaflets concerning such maladies, but translations of these excellent rules for their prophylaxis are issued in German, Dutch, French, Polish, Swedish, and Danish-Norwegian, in order to facilitate the operations of preventive medicine among the ignorant foreigners who find a refuge (too often, alas, only to abuse it) upon our shores. Some of these little pamphlets (as, for example, that on the prevention of typhoid fever, also reprinted in this report) are so clear, concise, and comprehensible, as to render them models of effectiveness. Indeed, so admirably are these sanitary tracts adapted to the end in view, that we deem them well worthy to form the basis of popular instruction, which, if given for a single day in the year in every public school throughout the United States, would, we believe, deliver the people of America from tens of thousands of premature deaths, and perhaps millions of cases of unnecessary illness annually. Dr. Baker estimates the total number of deaths from typhoid fever in Michigan at one thousand per year, and considers the proportion which deaths from typhoid fever bear to the total mortality throughout our Union is elsewhere at least equally great. The reply to the question as to how this enormous death-rate can be prevented he considers may be given in the four words, "Stop drinking contaminated water," and we wish that every physician, yes, every householder in America, who is inclined to be ignorant or careless upon this important subject, would spend his next leisure half-hour in reading over the convincing array of indubitable facts and cogent arguments mar-

shalled by Dr. Baker in favor of this great aphorism of practical hygiene.

A report of especial interest to the medical profession in Pennsylvania, and in several other States where boards of health have recently been created, or are soon to be established, is the first annual volume from the State of Maine. Among the valuable contents of this highly creditable document, the portion of greatest general interest is doubtless an account of the well-devised system of prophylaxis, so successfully erected against the introduction of smallpox from the neighboring Canadian provinces. The outbreak of variola in Canada having been allowed by ignorant and careless municipal authorities to assume such alarming proportions (a total of 3164 deaths being recorded), much anxiety was soon experienced in the neighboring States of Maine, New Hampshire, Vermont, and New York lest this loathsome disease should be conveyed across our frontier by persons endeavoring to escape from the epidemic. As an aid against the chance of invasion, a circular was addressed to the numerous proprietors or managers of lumber camps in the northern and eastern parts of Maine, urging them to compel every foreign workman to submit to thorough vaccination before giving him employment, and pointing out the methods of isolation and disinfection necessary should cases of smallpox appear. Thorough inspection and vaccination services were promptly instituted upon the railroads crossing the boundary-line, and so successful were the officials of the State board in their well-planned system of defence, that only three cases of smallpox or varioloid are reported to have occurred in Maine during 1885. Moreover, it is gratifying to relate that, although two of these attacks were sufficiently severe to prove fatal, the sanitary precautions of isolation, disinfection, vaccination, and re-vaccination were so stringently enforced, that no secondary cases developed from these otherwise dangerous *foci* of infection.

#### THE ACTION OF KAWA RESIN.

KAWA, the resin obtained by Lewin from the root of piper methysticum, whose action we have already referred to in the THERAPEUTIC GAZETTE for February and April, is still attracting considerable attention, and promises to become almost as valuable, provided it can be readily handled, as cocaine now is.

Dr. N. A. Randolph, in the *Medical News*, February 13, 1886, obtained results which, in the main, confirm those of Lewin, although the effects in his hands were not quite as marked as reported by Lewin. Dr. Randolph suggests the name lewinin for this resin, instead of the term alpha kawa resin, proposed by Lewin, who discovered it. The resin is a semi-fluid body, with a peculiar aromatic taste, pungent and hot like pepper; when placed upon the tongue, there is a momentary burning sensation, with increased salivary secretion, followed by local numbness, which may last for more than an hour. The kawa resin is too irritating to be applied to the human conjunctiva, but Dr. Randolph thinks that by first instilling cocaine, so as to render the conjunctiva insensitive, kawa might then be used to produce more prolonged anæsthesia. Its use in dental practice also suggests itself, and in the hands of aurists and laryngologists, though the facts that it is insoluble in water and glycerin, and that an alcoholic solution has serious disadvantages, will perhaps somewhat restrict its usefulness. It may, of course, be used in suspension in mucilage, but no reports have yet been published as to the use of the drug so prepared. The kawa resin can also, as we have already mentioned, be used as a means of disguising the taste of bitter medicine by rendering the tongue first insensitive by its application.

Still another use for the resin of kawa, or, as it is also spelt, kava, is in the treatment of gonorrhœa and acute affections of the urinary passages. As pointed out by Dr. Sanné, as long ago as 1876 Dr. Dupouy described the benefits obtained in the treatment of gonorrhœa by the decoction of kawa used as a stimulant in the Samoan Islands. The pain on micturition becomes less, the discharge decreases, and cure in many cases resulted in from ten to twenty days. Dr. Sanné has also himself had personal experience with the use of kawa in various diseases of the urinary apparatus, and he reports in the *Bull. Générale de Thérapeutique*, March 15, 1886, a number of cases in detail where this mode of treatment was employed. Dr. Sanné used kawa in the form of an alcoholic extract of the root, which probably closely corresponds to the resin described by Lewin. Sanné, however, calls it kavaine, which, while not an alkaloid, he thinks may perhaps be a glucoside. It is obtained from the bark of the root. He has made use of this alcoholic extract in pill form, each pill containing  $1\frac{1}{2}$  grains, which correspond to about 15 grains of the powder of

kawa. Eight to twelve of these may be given daily. They are well tolerated by the stomach, do not produce diarrhœa, eructations, or disturbance of appetite, have no effect on the skin, and produce no odor on the breath. They impart to the urine a slight odor, which is comparable to that of copaiba. He reports six cases in detail, in all of which cure resulted, one of spasmodic cystitis, one of inflammation of the prostate with double orchitis, three of acute gonorrhœa, and one of chronic gonorrhœa with suppurative orchitis. In the treatment of gonorrhœa the use of the kawa pills appears to have been the only medication employed.

#### PERMANGANATE OF POTASSIUM AS AN EMMENAGOGUE.

THE tendency to report our successes and to allow our failures to drop out of sight is inherent in human nature. Even when our failures are through no fault of our own, and might be instructive to others, we are very loath to believe them worthy of record; hence it is that in regard to almost any remedy medical literature abounds in laudations and successes, whilst reports of failure are rare, so that the balance of published accounts is almost always in favor of a drug or a measure, even though such measure may have been proven worthless and universally discarded.

These considerations have been brought to our minds by a recent perusal of the literature of metallo-therapy, a system of treatment which, if all that has been said of it were true, would be of great importance. Our readers may remember that as long ago as 1849 a French physician by the name of Burq discovered the alleged facts which are the basis of the system, and that being of a most persistent turn of mind, he pursued the subject in season and out of season until, in 1876, he persuaded the French Society of Biology to appoint a commission to investigate the truth of his assertions. This commission was composed of the most eminent of French neurologists, and, after three years, reported the correctness of the statements of Dr. Burq. The disease especially implicated in the method was hysteria, and the condition of hysteria in which there is lack of sensation, viz., hemianæsthesia. It was found that the hysterical patient varied in her relations with different metals; that in the one case the binding upon the anæsthetic surface of a disk of zinc would restore sensibility, or, in another case, copper

alone was successful, whilst a third case yielded perhaps only to the persuasive powers of silver, gold, platinum, or other precious metals. The commission further discovered that usually there was a transfer of the anæsthesia from one side to the other, so that whilst the left side, for instance, became sensitive under the application of the proper metal, the right would lose its sensibility. The capital therapeutic discovery of Burq was that if the metal which was found to be so related to the individual as when in contact with the skin to remove anæsthesia, was given in continuous dose internally, it produced a cure. This also was in a measure confirmed by the commission. In sundry cases, under the use of the elected metal, color returned to the face, power to the paralyzed arm, sensitiveness to the benumbed surface, joy to the distressed heart, and peace to the surrounding family. A lamentable "find" made by Prof. Charcot was, however, that the application of a metal to the healed surface was followed by a return of the symptoms, so that the clouds which had been dispersed would again make the landscape of the patient's future dull and leaden. Permanent satisfaction could only be obtained by fleeing from metals as from the unpardonable sin.

Great names are those which have vouchsafed the facts of metallo-therapy. Slight, indeed, has been the public denial, and yet who to-day uses metallo-therapy as a practical method of treatment?

In recent numbers of the *THERAPEUTIC GAZETTE* we have published, under the ægis of names scarcely less renowned than those which sanction metallo-therapy, the use of permanganate of potassium in amenorrhœa. As is known by everybody, the permanganate of potassium is decomposed with great certainty and rapidity by organic matter in the presence of an acid.

It seems to us very evident that the permanganate of potassium cannot exist for a few moments in the stomach without decomposition, and that as the permanganate it cannot ever get into the blood; if, therefore, it really has emmenagogue properties, such properties must be possessed by the salt of manganese which is formed in the decomposition of the permanganate of potassium. We would very much like to direct our readers to a clinical study of this subject.

In the first place, we wish extended the practical investigation as to whether the alleged results produced upon the uterus have not been merely accidental.

In the second place, if the permanganate be really found to be an emmenagogue, trials should be made with the acetate or other soluble salt of manganese.

We have very little doubt but that various practitioners have tried the permanganate, and almost as little doubt that it has been found wanting as an emmenagogue; but, from the considerations already given, the reports of failures are wanting. We would, therefore, ask any reader who has tried either *unsuccessfully* or *successfully* the salt, to let us know the general scope and the details of his experience.

If emmenagogue properties are possessed by the permanganate and also by the salt of manganese, the latter would be much the preferable, because less apt to irritate the stomach.

#### THE NEURALGIC DIATHESIS.

ONE of the so-called opprobria of the medical profession most frequently spoken of is neuralgia, and it may not be amiss to pause to think what we mean by this much-used word. Formerly almost all forms of nerve pains were spoken of as neuralgic, so that, whenever there was a lack of local lesions, such as abscess, boils, swelling, etc., the patient was said to be suffering from neuralgia. At present, by the acute diagnostician, very many of the cases which are still believed to be by the public suffering from neuralgia are recognized as sufferers from systemic or organic diseases. There are still, however, nerve pains for which we cannot account, and for which the name of neuralgic must be retained. In many of the most obstinate of these cases autopsies will show that the supposed neuralgic pain has arisen from a clearly defined incurable lesion; thus a clot forming near the trigeminal nerve-centre, or a spicula of bone hidden from view, and pressing upon a nerve in such a way as to irritate it without provoking a definite neuritis, would give rise to pain that during life should have to be simply termed neuralgia, and would resist all therapeutic treatment. Leaving out of sight these causes of hidden lesions, there remains a group of cases in which neither during life nor after death are we able to detect the cause of the pain. It would seem either that there is a molecular change in some of the sensory nerves or their centres so delicate as to escape our instruments, or else that there is a general condition of the nervous system which predisposes it to pain-storms. The essence of the

neuralgic diathesis may be considered to be a peculiar, excessive sensibility of the nervous system, which causes it to respond by pain to irritations so slight as not to be perceived, or scarcely to be perceived, by the normal nervous system. Thus most persons experience some uneasiness when a storm is gathering. Even the nervous system of cattle may be so perturbed as to give them warning of the approaching tempest. Hence the Texan steers gallop madly from the coming "norther" whilst the sky is still clear. At such a time the sufferer from the neuralgic diathesis responds to the atmospheric changes by a furious paroxysm of pain.

A very large proportion of cases diagnosed as neuralgia are undoubtedly cases of chronic gout. If the practitioner recognizes the true nature of these cases by regulating the habits, diet, and drugs of his patient, he can bring much of relief. There are, however, cases in which no evidences of inherited or acquired gout can be obtained, and we must acknowledge that there is a more or less incurable bodily habitual condition, which may be known as the neuralgic diathesis or temperament. This diathesis is often inherited, but is sometimes developed by prolonged bodily exhaustion and anæmia. When once acquired, this diathesis may persist, although the original cause has been removed. If the nervous system has been sufficiently long impressed, the pain tendency becomes stamped upon it precisely as the epileptic tendency becomes a part of the nervous system in a case of neglected reflex epilepsy, and remains after the removal of the original irritation. These neuralgic pains are to be recognized by their persistency, by the apparent absence of cause, by their occurring sometimes in one part of the body and sometimes in the other, and by the diagnostic exclusion of all other sources of pain. The acquired or inherited neuralgic temperament frequently is closely connected with or complicates pains of definite type; thus, cases of migraine occur in which, besides the typical paroxysms, there are occasionally seizures in various parts of the body, or, it may be, attacks of head pain, presenting none of the typical characteristics of migraine. Under these circumstances we may consider that there is a neuralgic temperament superadded to the inherited migraine. The neuralgic diathesis is undoubtedly closely allied to inherited gout, but the facts—that it so often corresponds with the general neurotic temperament; that it is so much more frequent in women than in men; that it so often prevails

in dry climates, whose tendency is to produce neuroses rather than gout; and, finally, that it so often occurs in persons free from other gouty symptoms—indicate that it is something more than gout. Even in recent books we read of cases of neuralgia with trophic changes, such as ulcerations, eruptions, etc. It is scarcely necessary to point out that in all these cases the supposed neuralgia is really due to some organic disease, which, in a large proportion of cases, is a neuritis.

---

#### THE SALICYLIC TREATMENT OF GLYCOSURIA.

---

FROM his recent valuable researches, Professor Latham concludes that there are two distinct kinds of diabetes. First, there is that which arises from a neurotic disturbance of the function of the liver; this has the effect of arresting the metabolism of the glucose, and allowing it to pass unchanged into the general circulation and appear in the urine. Second, that which arises from a neurotic disturbance of the function of muscle; this allows glucose to form in that tissue, and to pass unchanged into the general circulation and appear in the urine. He has also shown that this second kind of diabetes is intimately connected with rheumatism; so intimately, that a degree of more or less oxidation determines whether the muscular tissue generates an abnormal amount of lactic acid or of glucose in the system. Moreover, he has shown that, when salicylic acid is administered, it has the property of arresting the formation of both lactic acid and glucose, by means of a chemical combination which it forms with the antecedents of these products.

These views are, to some extent, confirmed by an article published in the THERAPEUTIC GAZETTE of last year, page 446, by Dr. Thomas J. Yarrow, in which are outlined four cases of the complete disappearance of sugar from the urine under the continuous administration of salicylate of sodium. In the *Brit. Med. Journ.*, May 1, 1886, Dr. Holden in a very valuable article calls attention to the rheumatic glycosuria, and reports six cases of rheumatic glycosuric patients in all of which the administration of salicylic acid produced a great reduction in the quantity of urine and entirely removed the sugar. In several of these cases there was no restriction in diet ordered. Dr. Holden has also used salicylic acid in four other cases in which no rheumatic symptoms existed, and in all failed to make

any impression on the polyuria or sugar. The first and most marked effect of the salicylic treatment, according to Dr. Holden, in the glycosuria of rheumatic persons, is the almost complete removal of the distressing polyuria which accompanies it.

In one case, after four days' treatment, the daily evacuation of urine was reduced from twelve to four pints, and, in all the cases, this effect was one of the earliest and most constant; at the same time there was a considerable fall, both in the specific gravity of the urine and its proportion of sugar; even when the treatment fails to remove the sugar entirely, it reduces it to such a trifling amount, that the patient is unconscious of any ailment, and gains in flesh and strength. This improvement persists for weeks after suspending the medicine; the quantity of urine never exceeds three to four pints in the day, nor does the specific gravity rise above 1028 or 1030, though containing sugar. Even this condition must be safer and less serious than when the patient is passing daily nine to twelve pints of saccharine urine, of a specific gravity of 1040 and upwards.

As to diet, the careful restriction which is so imperative in the diabetes of hepatic origin is not so necessary in this kind; still, Dr. Holden thinks it greatly helps to restrict the formation of glucose in the system, by prohibiting potatoes, farinaceous puddings, and sugar as much as possible.

In administering salicylic acid, the following mixture has given good results: *R.* Salicylic acid, ʒii; bicarbonate of sodium, ʒi; carbonate of ammonium, ʒi; mix in water, ʒi; and, when effervescence has subsided, add water to ʒxii. An  $\frac{1}{4}$  or  $\frac{1}{2}$  part to be taken three times a day. This is a soluble neutral mixture, and is not unpalatable when given in a wineglass of water, with a little tincture of orange-peel added. The ammonia prevents any depressing effects. Dr. Holden has tried the free acid made into 3-grain pills with mucilage, as recommended by Dr. Latham in rheumatic fever, but has not found them superior to the mixture, while many patients object to swallowing five or six pills as a dose.

It is a matter of much importance, with regard to treatment, to be able to distinguish between the two kinds of diabetes. The presence or absence of rheumatic arthritis, pains, and cramps is often sufficient; but Dr. Latham has recently called attention to a more certain mode of distinguishing between the two, as he has found that in the diabetes of rheumatic persons—that is, originating in the

muscular tissue—the urine contains some substance which dissolves cuprous oxide; so that a larger quantity of Fehling's test has to be added before getting the brown precipitate in this urine than in the diabetic urine of hepatic origin.

To judge from the proportion of cases of diabetes in rheumatic persons, this kind of glycosuria can be by no means rare; and the early treatment of it with salicylic acid offers a real hope of cure, or, at any rate, it will relieve and prevent that tendency to wasting and exhaustion which has but one issue.

#### ON MEDICINAL SOAPS.

WHEREVER the objects of medicinal therapeutics meet those of general hygiene, as, for example, in the questions pertaining to food, dress, lodging, and articles of toilet—on this border-line of medicine and the various branches of technology—the aims and abilities of physician and technologist are very apt to collide. While the former is inclined to treat purely technical problems from a rather abstract point of view, and lacks the proper auxiliaries of the artisan, the latter is often apt to encroach upon tasks of a strictly medicinal nature. No wonder, then, that the results of action of either side alone are imperfect and unsatisfactory, and that success can alone be expected from the harmonious co-operation of both the physician and the technologist. This maxim holds particularly true in reference to medicinal soaps. It cannot be doubted that in this instance we have to deal with a therapeutic object of great hygienic importance, which we must acknowledge has hitherto not received the attention from the part of the profession justly due to it. As soaps are being applied at the present day perpetually by everybody to one of the most important organs of the economy, the skin, it ought to be the duty of the medical guardians of the communities to inquire into their nature and qualities with the same interest as they examine the milk and meat of the household. This interest ought naturally be much more intense in the case of medicinal soaps, which hitherto have almost wholly been left in the care of the technical laity. It is not a rare occurrence to meet with skin-affections which have been either caused or aggravated by the use of medicinal soaps obtained by the patient on his own accord. It is thus that we can find an acne resulting from the use of the "infal-

libile tar soap," or an eczema of the worst kind after the application of the "all-curing sulphur soap."

It is the merit of Dr. Unna, of Hamburg, —favorably known to the profession by the introduction of ichthyol, the keratine pills, and the ointment-mull,—to have mended this deplorable state of affairs by having prepared, in connection with competent and well-known chemists, a series of medicinal soaps of a constant strength and undoubted purity.

In the *Sammlung Klinischer Vorträge* by Volkmann (No. 252) we find an essay of the distinguished German dermatologist treating exhaustively of this subject.

The arguments which Unna advances for the eligibility of soaps as a form of applying medicines deserve our fullest attention. The physiology of the skin teaches us that soaps, consisting principally of the secretion of glands of animal skin, are readily taken up by the epidermis. Next to an alcoholic or an ethereal vehicle, which penetrates deeper than soap, soap is for both physical and physiological reasons the promptest and readiest method to medicate the epidermis. It far surpasses in efficacy and reliability the vaseline, glycerin, or paste bases, and is particularly suitable for the various medicines having the character of a salt. Three other great advantages of the soap as a medium of medication are to be mentioned: viz., its antiphlogistic virtues, its economical nature, and its cleansing effects.

Unna regards as indications for the use of medicinal soaps the following: 1, a dermatosis of a universal but light nature which we desire to treat with as little molestation of the patient as possible; 2, if, during the suspension of a vigorous treatment, a milder and simpler medication is desired; 3, if, after the recovery from grave skin-affections, a milder but protracted after-action is intended; 4, if we deal with patients who show a peculiar predisposition for relapses of certain affections, such as eczema pruriginosum, psoriasis, etc. The great permeability of the upper strata of the human integument for soaps is, after all, in Unna's estimation, the greatest advantage in the use of medicinal soaps. He unhesitatingly declares that by the prolonged use of medicinal soaps the strongest impression can be made not only upon the skin, but also upon the entire organism. As an illustration of this influence, he cites the curative results of a thirty-three and one-third per cent. Hg. soap on syphilides of the skin and syphilis of other organs. In his practice he

has obtained such satisfactory results with this mercurial soap that he no longer resorts to the inunction cure. The advantages and peculiarities of the soaps prepared according to Unna's directions are in brief as follows: 1, as basis purest beef-tallow exclusively is used; 2, as alkalies freshly-prepared soda and potash lye are used; 3, all soaps are surcharged with fat (*i.e.*, they contain three or four per cent. of free fat in excess to the quantity needed for saponification) to prevent the congestion and desquamation following upon the prolonged medication of the epidermis by a neutral (medicinal) soap; 4, this surcharge of fat consists of olive oil (to eight parts of beef-tallow one part of olive oil is added); 5, the surcharge of fat allows of a better conservation and greater concentration of acids and easily decomposable salts, such as salicylic acid and corrosive sublimate; 6, the soaps contain not more than about fourteen per cent. of water; 7, secondary additions of glycerin and vaseline are excluded; 8, the soaps are not perfumed.

Unna details three methods of applying his "surfatted" soaps. The least energetic is the ordinary mode of washing. If a stronger effect is desired, he directs the affected portion of the skin to be covered with the lather of the soap and then to be rubbed with a dry towel. The greatest effect is, however, obtained by applying a thick lather to the skin and allowing it to dry without the use of water or towel.

The soaps which have been hitherto prepared and tested are the following:

1. Surfatted ground-soap, consisting of potash and soda lye. Use: as an ordinary soap, especially in children, and as a prophylactic agent for cracked and fissured hands.

2. Surfatted marmor soap. Composition: four parts of surfatted ground-soap and one part of finest marmor powder. Use: in acne and all parakeratoses.

3. Surfatted ichthyol soap. Composition: nine parts of surfatted ground-soap, one part of sulpho-ichthyolate of sodium. Use: in all forms of rosacea.

4. Surfatted salicylic soap. Composition: ninety-five parts of surfatted ground-soap, five parts of salicylic acid. Use: in subacute and chronic eczemata, acne, and parasitic affections of the skin.

5. Surfatted zinc-salicylic soap. Composition: eighty-eight parts of ground-soap, two parts of oxide of zinc, ten parts of salicylic acid. Use: in eczema, seborrhœa, hyperhidrosis, and bromidrosis.

6. Surfatted tannic acid soaps. Of these there are three kinds, made respectively with sodium, oxide of zinc and sodium, and zinc alone. Use: in eczema and pemphigus.

7. Surfatted rhubarb soap. Composition: ninety-five parts of ground-soap, five parts of alcoholic extract of rhubarb. Use: in parasitic skin-affections of a light type and inter-trigo.

In addition to these soaps which have received a sufficiently thorough clinical testing to claim our confidence, Unna directed the preparation of the following soaps for which neither indications nor effects have as yet been very definitely established: surfatted tar soap, containing five per cent. of *pix liquida*; surfatted sulphur soap, containing ten per cent. of sulph. præcip.; surfatted tar-sulphur soap, containing five per cent. each of *pix liq.* and sulph. præcip.; surfatted camphor-sulphur soap, containing five per cent. of camphor and ten per cent. of sulph. præcip.; surfatted camphor soap, containing five per cent. of camphor; surfatted borax soap, containing five per cent. of borax; surfatted iodide of potassium soap, containing five per cent. of iodide of potassium; surfatted naphthol soap, containing five per cent. of naphthol; surfatted naphthol-sulphur soap, containing five per cent. each of naphthol and sulph. præcip.

The carbolic soap prepared by Unna is, according to his own judgment, a useless article, which epithet he claims belongs to all so-called carbolic soaps in the market. With oxide of lead, arsenic, and the white precipitate Unna has also experimented in order to prepare soaps having these metals as bases, but has not yet reached the satisfactory results aimed at. The sublimate soap prepared by him has given very gratifying results in *psoriasis capitis*, *acne*, *lichen ruber*, *lupus*, and *syphilis*, but has not yet come up to the state of perfect stability attained in the other soaps.

The use of the medicinal soaps is still in its initiatory phase, but promises to expand into an ordinary and convenient mode of applying medicine after all technical difficulties have been successfully overcome.

#### ON LANOLIN.

IN the March issue of the GAZETTE our readers found a brief exposition of the practical uses of lanolin. We see from the reports of the European medical press that this

novel agent is rapidly gaining popularity, and fully sustains the anticipations with which its discoverer, Prof. Liebreich, of Berlin,\* introduced it to the professional world. In view of this fact it becomes a matter of necessity for the American practitioner to familiarize himself with the drug, which no doubt will soon appear in the American market. We therefore beg to represent somewhat explicitly to our readers our present state of knowledge on lanolin, its origin and properties. The wool of sheep, as taken directly from the animal, contains considerable quantities of fatty substances which have to be removed before the wool can be utilized. Formerly this fat was simply thrown away, and only recently—thanks to the economical tendency of our days—it has been collected and put to practical uses. Hartmann and Schulze were the first to chemically investigate this so-called wool-fat, and to demonstrate its actual composition, viz., ethers of fatty acids and cholesterin.

Liebreich went a step further, and showed that cholesterin fat occurred in all keratine tissues (skin, hair, whalebone, feathers of geese, chickens, etc.). Liebreich also showed that the cholesterin fat was not, as hitherto believed, secreted by the sebaceous glands, but was formed in and simultaneously with the keratine tissue. Lanolin, the cholesterin fat of the market, contains about twenty-five per cent. of water, and differs from all other fatty substances chiefly in resisting saponification and the influence of water. Hence lanolin has no tendency to become rancid.†

Dietrich‡ pointed out the therapeutically important fact that lanolin can take up a large amount of water (up to one hundred and ten per cent. of its weight) without losing its suppleness and ointment form, while unguentum paraffini under equal conditions can take up only four, *adeps suillus* only fifteen per cent. Equally readily can lanolin be incorporated with fats, oils, balsams, and most medicinal bases, furnishing ointments of a hitherto unattained efficacy and constancy.

The principal value, however, of lanolin consists in its unrivalled resorbability, insuring for the medicines incorporated with it the maximum amount of attainable efficacy. At the same time, it is certain that lanolin does not in any way injure nor irritate the skin.

\* Liebreich, it will be remembered, is also the discoverer of the hydrate of chloral.

† *Berl. Klin. Woch.*, No. 47, 1885; *Pharm. Zentralh.*, 1885, p. 534; *Pharm. Zeit.*, 1885, p. 872.

‡ *Pharm. Zeit.*, 1885, p. 978; *Deutsche Med. Woch.*, Dec. 1885.

Dr. Lassar has exhibited lanolin at his polyclinic for skin-diseases in Berlin in about four hundred patients, and regards its introduction into the Pharmacopœia as a desirable acquisition. Reporting his observations on lanolin in the December issue, 1885, of the *Deutsche Mediz. Wochenschrift*, Lassar pointed out the remarkable readiness of its absorption, and among other advantages of the drug mentions its minute distribution, which even allows of the entrance of cinnabar-lanolin into the deeper strata of the integument. Under the influence of lanolin, Lassar says, the skin assumed a peculiar tense condition, a state of turgescence which favors absorption of medicinal agents. Lassar also demonstrated to the Society of Physicians of Berlin, by microscopic specimens, that cinnabar and mercury allowed of a much finer distribution when combined with lanolin than with adeps.

If the skin is tender and irritable, lanolin does not cause œdematous swelling nor any other untoward symptom, as often observed under the influence of other fatty substances. The power of lanolin to penetrate into the deeper strata of the skin renders this agent peculiarly eligible in psoriasis, herpes tonsurans, chronic dermatitis, and the numerous skin-diseases marked by a callous condition of the epidermis. Again, the stated peculiarities of lanolin render it admirably fitted for the application of chrysarobin, pyrogallie acid, salicylic acid, naphthol, the preparations of mercury, resorcine, iodide of potassium, and *sapo viridis*. In this connection we recall the researches of Dr. Patschkowsky,\* with lanolin and potassium iodide; he proves that one-half to one hour after the inunction iodine could be recovered from the urine, while the experiments with the official ointment of iodide of potassium resulted negatively. Kaspar, of Geneva, obtained similar results.†

Prof. Fränkel, of Berlin, recommends lanolin ointments for application to mucous membranes, for he found them to prevent the formation of scabs and to diminish purulent secretions. Prof. Rübener noted also the superiority of lanolin in combination with preparations of mercury, sulphur, and tar. A five per cent. carbol-lanolin ointment has been found by Dr. Herrlich (of the German army) to produce local anæsthetic effects (*Pharm. Zeitung*, 1885, p. 978).

In Berlin, lanolin has been successfully tried in ischias (combined with ichthyol), in ichthyosis,

in hemorrhoids and burns (combined with cocaine).

In conclusion of these remarks, we state that in the majority of instances it will be necessary to add twenty per cent. of lard to lanolin in order to correct its consistency.

## Reports on Therapeutic Progress.

---

### THE THERAPEUTICS OF THE NEUROSES.

In the *Brit. Med. Journ.*, April 24, 1886, DR. E. E. LONG FOX publishes an extremely valuable paper on the therapeutics of the neuroses, which contains so many novel and important practical points that we offer a full abstract of it to our readers.

In the first place, although neuroses are devoid of any recognized pathological anatomy, there can be no doubt that they are evidences of depraved or disordered nutrition, or, at least, of abnormally altered relations between nerve-cell and supplying blood-vessel.

Neurotic patients frequently inherit from one or both parents the tendency to their peculiar nervous state; but a large number of neurotic phenomena occur in persons who have inherited no such history. They are met with after overpressure of study in the young, overwork of any kind in the adult, monotony of occupation, anxiety, hygienic conditions abnormal both as regards the healthiness of the environment and the proportion of brain-food to brain-work; and they mean partial starvation of the nervous centres.

A few of the chief neurotic symptoms are: dilated pupil; extreme mobility of the iris; a form of amblyopia that is reflex, of vaso-motor origin, induced by irritation of some of the branches of the fifth nerve, or of filaments from the abdominal or pelvic organs, carried to a vaso-motor centre, and causing constriction of the arteria centralis retinae, or probably sometimes of the vessels supplying the angular gyrus; hemiopia, associated with anæsthesia, and depending on disordered blood-supply to the posterior portion of the internal capsule; various forms of anæsthesia, often very localized, manifestations of a temporarily impaired circulation in the cortex or in the internal capsule, often due to the concentration of the patient's attention on pain elsewhere, or to her thoughts being directed to her emotions or to exalted aspirations; some forms of headache, especially migraine, and the so-called nervous head-

\* *Pharm. Zeitung*, 1885, p. 978.

† *Deutsche Med. Wochenschr.*, Dec. 1885.

ache often induced by late watching ; insomnia, particularly the form engendered by late intellectual work for some considerable period, and relieved by placing a patient for sleep in a nearly upright position, and administering food during the night, or by the administration of ergot ; tinnitus, which may often be reflex, and carried up to the tympanum by way of the inferior cervical ganglion ; abnormal acuteness of hearing, from ephemeral dilatation of a vessel supplying some of the auditory nuclei, or still more frequently the temporo-sphenoidal convolutions ; vertigo, either seeming to depend on slight alterations of pressure in the labyrinth, short of Menière's disease, or when there is a temporary deficiency in the circulation of the middle lobe of the cerebellum ; occasional abnormalities of depraved or deficient taste and smell. Motor phenomena in neurotics are so numerous that it is difficult to omit any abnormality of movement from this class ; tremor, as of the eyelids ; rigor without elevation of temperature ; convulsions, either epileptiform, or without complete loss of consciousness, and accompanied by movements of limbs either semi-voluntary or automatic ; opisthotonos ; hysterical vomiting, with no reflex connection with the pelvic viscera ; some varieties of chorea and of hemichorea ; paralysis, too universal to depend upon organic lesion, or localized, as of a finger, hand, or arm ; contractions, such as torticollis, varieties of talipes, bent arm, the body resting on the heels from flexion of the legs on the thighs ; these and many other advanced motor phenomena depend on emotion, and are produced by emotional irritation of vaso-motors in various regions of the brain and cord.

The hyperæsthesiæ of skin, such as are seen in some neurotics of unsound mind ; hyperalgesia, such as clavus, and the obscure inframammary pain, the tenderness of the hysteric spine, are due to dilatation of vessels in the sensory centres.

Among the psychical phenomena, it would be necessary to mention every manifestation of emotion. The subjects of "temper-disease" are probably invariably neurotic. Great excitability may be the rule, reaching on one side even to mania, especially religio-erotomania ; whilst in some cases, the melancholy tendency obtains, with concentration of thought on anything connected with the patient herself, especially her physical ailments.

Of sympathetic phenomena, some connected with the eye have been already referred to. Blushing, pallor, palpitation, faintness, irregu-

larity of heart, neurotic angina (in each case unassociated with organic lesion), various hyperæsthesiæ of the abdominal cavity, colic, gastralgia, enteralgia, hepatalgia, nephralgia, inertia of bowels, disordered secretions, some forms of diarrhœa, meteorismus, and phantom tumor are all connected with emotional action on the circulation ; either by way of the vaso-motor centres in the medulla, of the subordinate centres in the spinal cord, of the cervical ganglia, or of the great ganglia in the abdomen.

Among sympathetic phenomena may be placed the copious pale urine of the hysterical, and the various neuroses of the extremities. Of these, one of the most remarkable is the symmetrical gangrene of the extremities, occurring without blocking or disease of arteries.

It is seen, therefore, that the protean phenomena in neurotic patients are due to an abnormal excitability of the sympathetic nerves and ganglia. Given this excitability, the sympathetic system is played upon directly by emotion, reflexly by irritation, or by slight functional disturbance affecting a ganglion, or any nerve-twig leading to a ganglion. Although, therefore, the different neuroses may demand a treatment that varies according to the organ affected, yet no treatment is likely to be effectual that does not act on first principles, and endeavor to subdue, generally by means of nerve-tonics, this morbid excitability.

If one seeks a term that will express the predisposing cause for neurotic phenomena, one must use some word that will mean "starvation of nervous centres." This may be either a cell-condition *ab origine*, or a cell-condition induced by a disorder of vessel. Remedy for it may, therefore, take the form of better nutriment to the cells (fatty and farinaceous food), or of means that will improve arterial tone, and so foster a normal osmosis. Pretty frequently both classes of remedies are called for, and, in some cases, neither will be really efficacious until the patient is removed from an environment either of depressing circumstances, or of a malarial or other toxic atmosphere.

Besides the question of food, that of the promotion of a normal circulation takes first rank. Dr. Fox is speaking, of course, of cases in which there is no coarse lesion. In such patients, the occurrence of neurotic phenomena may be prevented by exciting a better condition of heart-action, by increasing arterial tension, or by obtaining both these effects.

Ammonia, ether, iron, digitalis, strophanthus hispidus, convallaria majalis, strychnine, belladonna, and, in very moderate doses, alcohol, stimulate the heart. It is nearly certain that, in a slight degree, alcohol in small doses really stimulates the heart, over and above its paralyzing effects on the vaso-constrictors. In a much slighter degree, arsenic and jaborandi are heart-stimulants. Arterial tension is increased by ergot, belladonna, the bromides, the acids, squill, Calabar bean, strychnine, nitrate of potassium, casca bark, and turpentine.

But over and above brain-feeding, and increase of cardiac action, or of arterial tension, there is something that takes place in the walls of vessels under the influence of such agents as arsenic, the salts of zinc, caffeine, nux vomica, guarana, etc., that seems to prevent undue constriction and undue dilatation of vessels, especially probably the smaller arterioles and the capillaries; the effect of which influence is to promote a normal osmosis, the taking in of supply from vessel to cell, the giving out effete material from cell to venule.

The important points in all neuroses are the abnormal influence of emotion, and the excitability of nerves and ganglia to reflex irritation. As the channel for the transmission of emotion is eminently a vaso-motor one, and as excitability to reflex irritation is evidence of deficient tone, it stands to reason that so-called sedatives are poor treatment. The tendency should be to give tone to the nerves and ganglia, vaso-motor and other; at first, perhaps, by ergot, by hazeline, by acids, by abundant food; and, later on, by iron, paying attention all through to mental influences.

In certain circumstances, a tonic treatment is not enough for reflex vomiting. A peculiarly difficult form to treat is the vomiting of phthisis, in which, presumably, irritation of the pulmonary branch of the vagus is carried to the medulla, and reflected down both on its gastric branches and on the phrenic nerves. This, even if very obstinate, may be met by hypodermic use of cocaine, though the *rationale* of its effect is not well known. It may act by causing anæsthesia of the pulmonary branches of the vagus, or by rendering the centre of the reflex arc less easily excited. In the latter case, it may have a tonic effect by its constricting power over vessels.

It would not be right to call chorea invariably a neurosis. Some cases, and generally those the least amenable to treatment, depend on organic lesions; but, in the large majority of cases, no such lesion exists; and in them a sedative treatment acts very imper-

fectly, as compared with a tonic. The salts of most of the metals are useful in this relation, and those of arsenic and zinc pre-eminently so. In low-lying districts with a damp soil, the consensus of large bodies of medical men is in favor of iron; and, doubtless, in this respect, the particular therapeutical agent will vary with the surrounding circumstances; but the principle is the same.

Then, again, as to the imperfectly known neuroses of the extremities:

1. A tingling is met with of all the extremities, both hands and both feet; sometimes with a normal appearance of the skin, sometimes with a waxy blanching. It is a neurosis, but a neurosis depending upon a great variety of causes. The tingling is a reflex manifestation of irritation at a distance, in the stomach, uterus, intestine, etc.; perhaps sometimes from the peripheral nerves themselves, exercising a paretic effect either on portions of the cortical sensory area or on the cervical and lumbar bulbs, or on all these coincidentally, or on the vaso-motor ganglia on the vessels themselves; or it may be due to deficient heart-power, and then is accompanied by the waxy blanching of the skin, and with more or less local loss of temperature.

2. Cases are met with in which both cerebro-spinal and sympathetic nerves are involved; and pain, heat, and vascular congestion alternate with pallor, cold, and absence of pain.

3. There is a state of semi-paralysis of the blood-vessels of the extremities, causing flushing of the feet, and generally pain and tenderness. Pain may precede the vaso-motor phenomena. The feet are more commonly affected than the hands.

4. There may be a great coldness of the feet, or of the fingers, associated with contraction of the vessels of the extremities. It is possible that this condition is closely allied to the first variety, and may depend on deficient *vis à tergo*; but it has been thought to be due to overexcitation of the vaso-motor centre.

5. A further stage of this, even if it may not be considered a separate variety, is one in which symmetrical gangrene is the direct result of contraction of vessels. In all these varieties, the vessels themselves are neither occluded nor diseased. It would be against experience to say that these neuroses occur only in patients who have inherited a neurotic tendency. They seem frequently to be set up by the circumstances of the environment. Some varieties are associated with

dilatation of vessels, and in these the use of ergot and of nerve-tonics is essential; but in the forms that own a constriction of vessels, the opposite treatment would hardly be successful. Friction, gentle galvanic currents, tonics, the removal of the sources of reflex irritation, and a due regard to a sufficient *vis à tergo*, will do more than paralyzing drugs, or even than the application of external heat.

In the same line of thought, much might be said on many of the neuroses; on exophthalmic goitre, which, in some of its phenomena, may be included in this category; on diabetes insipidus, often recovered from under ergot and galvanism; on vaso-motor insomnia; on heat-exhaustion and heat-fever, in the first of which depression of nerve force must be met by strengthening remedies, in the latter, the paralysis of heat-controlling centres by quinine; on the non-organic forms of angina pectoris, in which the recurrence of the attacks would be badly met by sedatives and antispasmodics.

#### THE PHYSIOLOGICAL ACTION OF BENZOYL-ECGONINE.

MR. RALPH STOCKMAN has published in the *Pharm. Journ. and Trans.*, April 24, 1886, a study of the physiological action of benzoyl-ecgonine. He has found that when  $\frac{1}{16}$  to  $\frac{1}{8}$  grain is administered subcutaneously to a frog the animal remains apparently unaffected for half an hour or more, at the end of which time it begins to develop signs of muscular stiffness, and shows great unwillingness to move. The pupil gradually becomes dilated. In eighteen to twenty-four hours after administration the reflexes become greatly exaggerated, this increasing until the slightest irritation brings on a tetanic spasm. This condition may last one or several days, and the frog ultimately recovers or dies of exhaustion. Such, briefly stated, are the effects of a medium dose, the same train of symptoms being manifested in a greater or less degree with larger or smaller amounts.

Division of the spinal cord at the medulla had no effect in stopping the convulsions after they were once established.

**Action on the Heart.**—With moderate doses the rapidity of the heart's action was increased, while large doses, after inducing great irregularity of action, caused it to stop in diastole.

No effect on the vessels of the web could be observed.

**Nervous System.**—The spinal cord, as before indicated, is thrown into a state of great reflex excitability, exactly similar to what occurs in strychnine-poisoning.

The sensory and motor nerves remain quite unaffected.

**Striped Muscle.**—It acts as a muscle-poison apparently similar to caffeine, but not nearly so active.

On mammalia he has not had sufficient material to carry out a satisfactory number of experiments. A rabbit which received 24 grains subcutaneously remained apparently little affected.

Cats are more susceptible. On administering 24 grains subcutaneously, the animal shortly after became very uneasy, and was seized with diarrhoea and vomiting, while the pupils were very dilated. Half an hour after, a violent tetanic spasm supervened. During the next few hours the animal had almost continuous convulsions, and finally died of exhaustion. The heart was in diastole, and the small intestines so firmly contracted as almost to occlude the lumen.

From the foregoing description it is evident that benzoyl-ecgonine is practically identical with caffeine in its action, although there are some minor points of difference.

The chief action of cocaine, namely, paralysis of sensory nerves, is quite absent; in fact, the relationship between the action of the two substances seems to be as profoundly altered by the subtraction of a methyl-group ( $\text{CH}_3$ ), as is the case with methyl-strychnine and strychnine.

#### THE COCCI OF CROUPOUS AND HYPOSTATIC PNEUMONIA.

DR. LEBASHOFF publishes in the *Russian Weekly Clinical Gazette* an account of some observations made with a view to determine the frequency with which microbes are present in cases of croupous and hypostatic pneumonia. He examined sections, the liquid contained in the lungs, the contents of the smaller bronchi, and also the fluid of the cerebral ventricles, and in some cases the blood from the heart and large venous trunks. The ordinary methods of staining not being very satisfactory, the author undertook a series of observations for the purpose of improving upon them, and found that the best method of staining lung-sections was to immerse them for from two to five minutes in an aniline solution of gentian violet, and afterwards for from four to fifteen minutes in an aniline or watery solution of eosin, then to wash them

and dry them with alcohol, and finally to treat them with clove or cedar oil. By this method of staining the micro-organisms could be seen to be distributed in a very irregular way, usually in groups. The cocci found in the centre of a lobulus always preserved their ordinary form, and were strongly stained; while single cocci towards the circumference were often hardly to be distinguished, being but slightly stained. While some of the cocci presented a distinct envelope, others apparently of the same variety were seen close to them without any envelope at all. The size of the pneumococci was not constant, this being perhaps due to the manipulations the sections had undergone in preparing them for examination. The cocci seen by the author entirely corresponded with those described by Friedländer. Altogether there were examined forty-eight cases, forty-one of croupous and seven of hypostatic pneumonia. In the latter class of cases it did not seem that any characteristic cocci were constantly present, while in the forty-one cases of croupous pneumonia Friedländer's cocci were found in the lung-tissue in thirty-eight cases. In eleven of these the fluid of the cerebral ventricles was also examined, cocci being found in eight. In the earlier stages of the disease the number of cocci was small; this gradually increased, attaining its maximum when red hepatization was changing into gray. The blood was examined in twelve cases, but no pneumococci could be discovered. The observations were carried on by cultivations in jelly and inoculations of animals. For cultivations in jelly the liquid from the lungs, the blood, and the fluid of the cerebral ventricles were used. Two kinds of colonies were met with. One kind was obtained after inoculation not only of pneumonia but of other diseases, and of putrescent blood. The second kind differed from these in being of a dull white without any admixture of gray, and in being distinctly raised above the surface of the jelly. This kind was only observed after inoculation from croupous pneumonia. From ten inoculations with pneumonic lung-juice these colonies were obtained eight times; five inoculations with ventricular fluid were twice successful, and three inoculations with blood only once. Experiments with mice showed that when these animals were inoculated from colonies of the second kind they developed croupous pneumonia, and in one case out of three in which the grayish cocci were inoculated croupous pneumonia also followed. The author remarks that further observations are necessary

on this subject, since mice are very subject to croupous pneumonia, and it is possible that numbers of other micro-organisms may have the power of setting up the disease in them.—*Lancet*, April 17, 1886.

#### CIRCUMCISION UNDER COCAINE.

Various experiments have been made with solutions of the hydrochlorate of cocaine with the object of producing such local anæsthesia of the prepuce as would result in a painless circumcision. The results of quite a number of such efforts, while greatly lessening the pain of circumcision, have not been entirely satisfactory. In the last two operations, however, which Dr. F. N. OTIS (*N.Y. Med. Journ.*, May 8, 1886) reports having done by a new procedure, the first was entirely painless; in the second there was only slight sensitiveness in putting in the last few stitches.

The plan pursued was as follows: Retracting the prepuce, 3 or 4 drops of a six per cent. solution of hydrochlorate of cocaine were injected with a fine hypodermic needle into the internal layer of the prepuce about half an inch from its attachment at the base of the glans penis. This was done so superficially that, as the needle was withdrawn, a little bleb was formed nearly half an inch in length. Waiting for half a minute, the needle was again introduced at the opposite side of the bleb, and it slid in painlessly for another half-inch in the line of the circumference of the penis. In this manner blebs were made until the cervix was completely encircled by them.

The prepuce was then drawn forward, and, by a simple procedure, another line of blebs was made to encircle the external preputial layer at the point elected for the incision. This was intended to be directly opposite the line of injection of the internal layer. The prepuce was then advanced so that the line of injection cleared the end of the glans, at which point it was compressed by a clamp, and excised without the least pain.

The clamp was then removed, the internal layer of the prepuce was slit up, turned back, trimmed with the scissors, and attached to the incised edge of the external layer by continuous suture, comprising about twenty stitches. Not the least pain was experienced in the operation except that caused by the first introduction of the needle in the internal layer, and the same in the external layer. Twenty drops of the six per cent. solution

were used in this case. In the second 25 drops of a four per cent. solution were injected. The chief embarrassment of the operation consisted in the fixation of the delicate tissues so as to introduce the needle with accuracy, superficially, and to a sufficient extent. An ordinary mouse-tooth forceps answers very well, but a forceps in which the needle can ride would be an advantage.

#### TREATMENT OF ACNE.

DR. MAHLON HUTCHINSON believes that in ninety per cent. of the cases of acne of all forms, the exciting cause lies in the genito-urinary organs. Acne may be said to almost invariably manifest itself at the age of puberty, and this happens in such a large and overwhelming majority of cases that it must be considered as more than a coincidence. Until recently he had treated all his cases of acne, with few exceptions, with potassium bromide, and tincture of gelsemium, accompanied with local applications of green soap and sulphur ointment, the success, however, being barely moderate; it then occurring to him that there might be some connection between the occurrence of acne and the genito-urinary organs, he commenced using the cold urethral sound, and he stated that his success was startling often to himself. In one week the improvement was very noticeable, and in six weeks he might have dismissed them cured to all external appearances. He states that in these cases, as in all others, there is actually nothing to direct one's attention to the genital organs, and yet he finds in the last twelve months that of the nineteen cases of acne which he has treated in the male, and seven in the female, fifteen of the former and six of the latter have recovered entirely, while the other five did not continue their treatment long enough to form any opinion of his success or failure. In most of his cases the sound was used exclusively, although he also invariably gave a placebo. His plan has also been for the first three weeks to give some laxative preparation accompanied by the local application of green soap, benzoin, and sulphur ointment. The improvement, except in the mildest cases, is scarcely if at all perceptible. At the end of three weeks he is then in the habit of proposing the use of the cold sound, and, after carefully and plainly explaining its nature to the patients, he has never yet met with a refusal to try its use. One or two weeks only are needed to prove the success of his treatment, and in one or two

months the skin will be free from acne, but with numerous scars left to remind them of the past. As regards the treatment of acne in the female the cold sound would be useless, while its analogue, the uterine sound, would also, for numerous reasons, be out of the question, there being no probability of benefit derived from its use. But the object is to reduce the supposed hyperæmia and allay irritation; this he finds is readily accomplished by means of the hot douche, and he finds that that being the case, acne is also readily cured in the female by the simple use of the hot vaginal douche. Six out of seven cases thus treated have been eminently successful. Dr. Hutchinson reports five cases treated in this way in detail, in all of which success was obtained. He further adds that in the mild forms of acne local medication, aided by the internal exhibition of arsenic, is sometimes sufficient to produce cures. In those, however, to which he alluded as cured by this method, the treatment with the cold sound and hot-water douche, the mild types have been excluded. As adjuvants to the cold sound and hot-water treatment he has used the following prescriptions, but has derived but little benefit from them when used alone:

℞ Tr. benzoin. simp., ℥ss;  
Aque, ℥i. M.  
Sig.—Face-wash.

℞ Sap. viridis, ℥viii;  
Aq. cologn., ℥iv. M.  
Solve et filtra. Sig.—To be used as cleansing face-wash.

℞ Sulphur precip., ℥ii;  
Ung. vaseline, ℥vii. M.  
Sig.—Apply once a day.

The above is a useful ointment, more useful, however, in acne rosacea than in acne vulgaris.

As a laxative mixture the following:

℞ Ferri sulph., gr. xv;  
Acid. sulph. dil., ℥iiss;  
Magnes. sulph., ℥ii;  
Aque, ad ℥vi. M.

Sig.—Two drachms half an hour before breakfast in half a glass of water.

Arsenic given in the following form is sometimes quite efficacious:

℞ Sol. arsen. br. (Clemens), ℥ii;  
Aque, ad ℥iv. M.

Sig.—One drachm t. i. d., gradually increased to two drachms t. i. d.

*A NEW METHOD OF ESTIMATING THE  
CONDITION OF THE RIGHT SIDE  
OF THE HEART.*

In September, 1885, DR. W. PASTEUR called attention to a distention of the superficial veins of the neck which occurs when, under certain circumstances, pressure is exerted over the liver. He has since then had an opportunity of examining a large number of patients with positive and negative instances of this phenomenon, and he records the results of this examination in the *Lancet*, May, 1886.

The physical sign in question is a distention or overfilling of the external jugular veins, apparently from below, with or without pulsation or undulation, which takes place when pressure is exerted in the right hypochondriac or epigastric regions with the flat of the hand, the direction of pressure being backwards and upwards. Before proceeding to make the examination the patient should be placed in the recumbent posture, with the neck slightly extended and the head turned a little to one side, while care is taken that the muscles of the neck are not in a state of tension. The sign is usually best marked on the right side, but may in almost every case be demonstrated on the left side also. It is essential that the movements of respiration should be normally maintained throughout the examination.

He has frequently observed a partial filling-in of the supra-clavicular fossa at the moment when pressure is first exerted. This is especially marked in thin subjects, and may be accounted for to some extent, perhaps, by simple mechanical displacement, but is chiefly due to an involuntary arrest or modification of breathing, and almost invariably subsides in a few moments. The amount of pressure required varies in different individuals. In rare cases rigidity of the abdominal muscles renders the manœuvre quite impossible. The presence of moderate ascites is no impediment, but excessive distention of the abdomen with fluid or gas renders the necessary manipulation more difficult and sometimes impossible. The pressure should be exercised gradually and steadily, otherwise an attack of coughing is liable to be induced, particularly in cases of bronchitis. The patients rarely complain of any pain or even discomfort, but on the occurrence of the least pain the manipulation should be at once discontinued.

Dr. Pasteur reports a case which affords a good illustration of this phenomenon, and he

believes that it is invariably met with in cases which show evidences of great over-distention or failing compensation in the right heart. He believes it to be invariably present in well-marked tricuspid incompetence, whether functional or due to disease of the valves. But besides these there are a considerable number of cases which ultimately recover, in which the sign is present with varying intensity at one period or other of the illness. Such are instances of mitral valvular disease, whether regurgitant or stenotic, and of chronic pulmonary emphysema, complicated with acute or severe general bronchitis. The question naturally arises, whether the distention in these latter cases (emphysema, etc.) should be regarded as evidence of slight tricuspid incompetence or simply of great over-distention of the right heart falling short of failure of the tricuspid valve. It is to be noted that these are precisely the cases in which the question of tricuspid incompetence has to be considered from a prognostic point of view, and is often left undecided. Venous pulsation is generally absent, and often the cervical veins are but slightly distended. Not infrequently there is undulation at the spot where the distention of the vein ceases. This may be systolic only, or double, and synchronous with the heart-beats. The valves in the external jugular veins are usually competent, and the veins empty completely with each inspiration. The effect of pressure below the ribs varies in these cases with the amount of obstruction to the venous return: 1. In the least-marked cases, the vein, although not perceptibly distending under the pressure, is seen, nevertheless, not to empty completely during inspiration. 2. In others a degree more severe, a moderate distention results; the vein becomes visible as far as the anterior border of the sterno-mastoid muscle, more rarely as high as the angle of the jaw. At the same time the spot where undulation was visible becomes shifted higher up the vein, and the character of the undulation is not infrequently modified, the double variety being replaced by a single systolic flicker, the single variety occasionally disappearing altogether. 3. In cases yet more severe, but in which the usual signs of tricuspid regurgitation are not developed, the pressure sign is often elicited with great distinctness, with or without undulation, and is here to be regarded as indicating early tricuspid failure. In the second class of cases, which differs from the third in degree, only there is great over-distention of the right heart, falling short, however, of re-

gurgitation, possibly with excessive strain on the valve-cusps.

The mechanism of the production of this phenomenon is probably complex. Without presuming to offer a complete explanation, Dr. Pasteur suggests that the following factors probably enter into it: 1. Compression of the inferior vena cava by the liver, especially in cases where this organ is enlarged. This factor, however, probably acquires more importance in cases of tricuspid regurgitation, with pulsating liver. 2. Lessening of the inspiratory action of the thorax through interference with the movements of the diaphragm. 3. Direct mechanical interference with the proper movements of the right side of the heart. A glance at the anatomical relations of the right auricle and ventricle to the diaphragm and subjacent liver will suggest the possibility, not to say probability, of such interference.

There can be little doubt that the effect of subcostal pressure, whatever the mechanism of its action, is to put increased difficulties in the way of the proper action of the right side of the heart, so that the pressure-sign in cases where the tricuspid valve is considered to be still competent is to be looked upon as a measure of the capacity still possessed by the right heart to combat increased resistance. In cases where the tricuspid valve is incompetent, the effect of the pressure is to aggravate the conditions under which the heart is already unable to do its work, with a proportionate increase in the signs of that inability. This subcostal pressure-sign possesses undoubted value as a means of diagnosis, and may also afford valuable information as to the progress and ultimate prognosis of many cases in which we are now reduced to mere conjecture for want of some definite, tangible index of the condition and working power of the right side of the heart.

#### A NEW DIAGNOSTIC TEST FOR TYPHOID FEVER.

Statistics regarding the therapeutics of typhoid fever are almost always seriously vitiated by doubts as to diagnosis. This is more especially the case with the alleged abortions of typhoid. It is very desirable, therefore, to have some definite test of the presence or absence of the disease in its early stages. The temperature curve is known to be often far from typical; the roseola does not appear, if at all, until from seven to twelve days; there are, in fine, no pathognomonic symptoms in the earlier stage of the disease.

Several observers have recently tried to establish a method of making the typhoid bacillus of Eberth a means of positive diagnosis. This bacillus is now quite generally conceded to be a constant accompaniment of the disease in question, and of no other.

Attempts to find this bacillus in the blood have not been very successful, although Neuhaus (*Berlin. Klin. Wochen.*, 1886, No. 6) observed them in blood taken from incisions made near the roseola spots. M. Bouchard has also found the bacillus in the urine. Recently Philipowicz (*Wien. Med. Blatt.*, 1886, Nos. 6 and 7; *L'Union Médicale*) has communicated the results of his personal experience in the examination of blood drawn from the spleen of typhoid patients. Having washed the skin with a solution of bichloride, 1 to 1000, he inserted the needle of a hypodermic syringe, previously sterilized, between the ninth and tenth ribs, and withdrew some of the splenic blood and juice. In this he was able to recognize the bacilli of Eberth, and produced cultivations showing their specific character. All this was done in four patients, before the appearance of any roseola. There does not seem to be any great inherent difficulty in using this method of testing the nature of a suspected fever, provided, of course, that subsequent experience confirms the results of Philipowicz. Such a method cannot be made a routine one, but in hospitals it may be frequently used, and by it perhaps the much-disputed question as to whether typhoid fever is ever aborted can be settled.

In this connection the editors of the *New York Med. Rec.*, May 22, 1886, call attention to the daring experiments of M. Payon (*L'Union Médicale*, No. 115, 1885), who inoculated pure and attenuated cultures of the typhoid bacillus upon himself and five other persons, without producing any definite symptoms of typhoid fever as it occurs in man.

#### THE ACTION OF ANTIPYRIN.

DR. J. H. FRANKENBERG reports in the *Med. Rec.*, May 22, 1886, that his experience with antipyrin for the last eighteen months warrants the following conclusions:

1. We possess in antipyrin an antipyretic which will reduce temperature most powerfully and rapidly.

2. It is in the great majority of cases perfectly safe; only in very much depreciated states and in delicate children must it be warily given and guarded by cardiac stimulants.

3. It lacks nearly all the disagreeable features which other antipyretic drugs possess. Perspiration occurs in a large proportion of cases, but does not seem to enervate the patients or render them uncomfortable. Pruritus occasionally coexists with the eruption. Vomiting now and then occurs.

4. It may readily be introduced into the system through various channels. Its taste is not particularly disagreeable, and may be easily disguised by some aromatic. Hypodermically given, it acts more decidedly and rapidly, and avoids the possibility of disturbing the stomach. It is unirritating. It may also be given per rectum.

5. It cannot cope with quinine as an antiperiodic or tonic, nor with salicylic acid in acute articular rheumatism.

6. It has practically no influence upon the pulse and respiration. If the pulse be dichrotic, the secondary wave entirely, or nearly, disappears. In other words, it raises the arterial tension.

In conclusion, he says that very little doubt is entertained but synthetic chemistry will develop many new compounds which may prove of avail at the bedside as antipyretics; but it is our firm conviction that at the present day antipyrin, in sufficiently large doses, is the most powerful, the most certain, and the safest antifebrile drug that we have in our materia medica.

#### CONTRIBUTION TO THE KNOWLEDGE OF ALBUMINATES IN MILK.

SEBELIEN describes in the *Zeitschrift für Phys. Chemie*, vol. ix. p. 444, two new albuminates of milk besides caseine, viz., lactoglobulin and lactoalbumen.

1. To obtain lactoglobulin, the milk is first carefully neutralized with soda lye, in case it be of an acid reaction, and then saturated with chloride of sodium. The filtrate on being warmed produces a flocculent precipitate, which consists principally of phosphate of lime; the filtrate of this, on being saturated with sulphate of magnesium, precipitates lactoglobulin. The percentage of lactoglobulin contained in milk is very small.

2. Lactoalbumen is obtained by adding one-fourth per cent. of acetic acid to the filtrate of milk, mixed with sulphate of magnesium. By solution in water, dialysis, precipitation of the remaining solution through alcohol, and washing with alcohol and ether, lactoalbumen can be obtained as a white powder, wholly soluble in water. Lactoalbumen

is by no means identical with serum albumen, and differs from caseine in containing a higher percentage of sulphur (the former having fourteen per cent., the latter seven per cent.), and a lesser percentage of phosphorus.

#### THE CIRCULATORY AND RESPIRATORY CHANGES IN ANIMALS PLACED IN THE PNEUMATIC CABINET.

The great objection to the use of the pneumatic cabinet has been that we have no knowledge of the physiological effect of rarefied and compressed air applied under these conditions on the respiration and circulation. These conditions have been investigated by PROF. H. N. MARTIN and DR. FRANK DONALDSON, who have published their results in the *New York Med. Journ.*, May 15, 1886. Their experiments were made on rabbits narcotized with chloral in whom the trachea was connected with a Marey's tambour, which recorded on the kymograph paper the rate and extent of breathing movements, while the arterial pressure and pulse were recorded at the same time. The authors have tabulated their results as follows:

I. When the animal is breathing air from outside the cabinet, rarefaction of air within the cabinet causes a marked fall of general arterial pressure, but has no influence on the pulse-rate. The fall of pressure lasts a short time only (ten to twenty seconds), and is followed often by a temporary rise above the normal.

II. This fall of systemic arterial pressure depends on two factors: greater flow of blood to the skin when the air around the animal is rarefied, and greater accumulation of blood in the lungs when they are distended.

III. Of these two factors, accumulation of blood in the lungs is the more effective; for, if the animal breathes air from the cabinet and not from outside, rarefaction of air within the cabinet (in this case accompanied by no special expansion of the thorax) has but a trivial effect in lowering arterial pressure.

IV. When the animal is breathing external air, rarefaction of the air within the cabinet usually has no effect upon the respiratory rate or the extent of individual respiratory acts, unless the fall of blood-pressure is considerable. If it is considerable, symptoms of anæmia of the medulla oblongata are seen. In most cases there is more forcible dyspnoic breathing; in some there are dyspnoic con-

vulsions similar to those which occur when an animal is bled to death, and due to the same cause, viz., deficient blood-flow to the respiratory centre.

V. The rapid recovery of general arterial pressure, while the animal is still in a rarefied atmosphere but breathing external air, is probably due to excitation of the vaso-motor centre, which, as is well known, is excited whenever its blood-supply is defective.

VI. The brain, inclosed in a rigid box, which is practically unaffected by variations in atmospheric pressure, has its circulation more disturbed in the pneumatic cabinet than any other organ except the lungs.

VII. Compression of the air within the cabinet, while the lungs are in communication with the exterior air, causes a considerable but transient rise of blood-pressure. This is probably mainly due to the forcing of blood from the cutaneous vessels; but the authors have not yet had opportunity to thoroughly investigate this point.

VIII. Compression of air within the cabinet, while the lungs are in communication with the exterior air, slows the pulse as the arterial pressure rises. This is probably due to excitation, by increased intra-cranial blood-pressure, of the cardio-inhibitory centre; but further experiments are necessary before this can be positively stated.

IX. In certain cases, when the air within the cabinet is rarefied and the animal is breathing external air, the respiratory movements cease altogether for several seconds. As to the cause of this physiological "apnoea" the authors are not yet ready to form an opinion. It may be due to the extra accumulation of air in the alveoli of the lungs, or to distention of the lungs exciting those fibres of the pneumogastric which tend to check inspiration.

Such, in brief, being the physiological effect of rarefied and compressed air as applied in the Ketchum cabinet, how should this knowledge affect the practical use of this apparatus? It having been found that even very great rarefaction of the air in the cabinet produces but slight effect on the circulation, provided the animal is breathing the air within the cabinet, Dr. Donaldson concludes:

1. That rarefaction of the air when the person first enters the cabinet (as directed by Mr. Ketchum), in order that the residuum air may expand, and so drive out any plugs of mucus in the lungs, may be done without danger to the individual. In view of the great and sudden fall of arterial pressure when the ani-

mal is breathing outside air, and the air within is rarefied, he concludes:

2. That the air in the cabinet should never be suddenly rarefied, and that the motion of exhaust should invariably be slowly made, and the amount of rarefaction small, particularly at the first treatments. This sudden fall of arterial pressure depending as it does upon an increased blood-flow to the skin and an accumulation of blood in the distended veins and lung alveoli, he concludes:

3. That, before deciding a person to be a proper subject for treatment by pneumatic differentiation, *thorough examination* should be made of the *heart*; and that no person found to have pronounced insufficiency or stenosis of the mitral valve, or the slightest tricuspid regurgitation, should, under any condition, be placed in the pneumatic cabinet; for it is plain that rarefaction of the air would be most dangerous in such cases. The fall of arterial pressure would seem to depend chiefly upon the accumulation of blood in the lungs, for, if the animal breathes air from the cabinet and not from outside, rarefaction of air within the cabinet has but a trivial effect upon arterial pressure. From this fact he concludes:

4. That the liability to pulmonary hemorrhage is very slight, though greater perhaps than Dr. Williams has supposed. It having been proved that compression of the air within the cabinet, while the animal breathes external air, causes a considerable rise in arterial pressure, and slows the pulse from the increase of intra-cranial blood-pressure, he concludes:

5. That old persons, with possibly atheromatous arteries, are not, generally speaking, proper subjects for the pneumatic chamber, especially where their trouble is emphysema or asthma, and compression of the air within the cabinet is made use of in order to assist expiration.

Again, in view of the sudden and pronounced fall in arterial pressure following rarefaction, and of the considerable though transient rise of the same following compression of the air in the cabinet, he concludes that the method of differentiation should be practised with much care and discrimination in all cases, and that the actual movements of exhaust and compression should be made always very slowly and gently.

Finally, the Ketchum cabinet should be in the hands of careful auscultators only, for in those of the inexperienced or careless great harm may be done.

*SYPHILIS AS A FACTOR IN EAR-DISEASE.*

WOAKES believes that syphilis is a frequent cause of obstinate otorrhœa (*Centraibl. f. Med. Wissen.*, No. 1, 1886), and usually affects both ears. Caries is an almost permanent complication of syphilitic otorrhœa. Finding in several cases of otorrhœa with a syphilitic base that the cicatrices of leech-bites assume a copper hue, Woakes recommends the application of leeches for diagnostic purposes in doubtful cases.

The same author publishes a case in which he felt justified in diagnosing a gumma in the tympanic cavity. A man, 25 years of age, had acquired a chancre two years ago, and suffered for three months from hard hearing and tinnitus aurium. The tympanic membrane was found to be normal, but an opaque mass could be seen through it, which reached very near to its inner surface. Besides, there existed a catarrh of the Eustachian tube and the pharynx. The local treatment remaining without success, Woakes ordered inunctions of blue ointment nightly, and found the hard hearing and the mentioned opaque mass disappeared after two weeks.

*THE ACTION OF KAKODYLIC ACID ON THE ANIMAL ECONOMY.*

The only arsenic compounds in which the toxic properties of the arsenic are doubtful are the so-called arsenic methyl bodies or kakodylic compounds, and even as regards these there is much conflicting testimony. This is especially the case in regard to kakodylic acid, and therefore, as tending to clear up this matter, the experiments of Drs. JOHN MARSHALL and WALTER D. GREEN (*Amer. Chem. Journ.*, May, 1886) are particularly of interest. These authors quote a number of authorities, which seem to show that large doses of this substance may be introduced into the animal economy without producing the slightest symptoms of poisoning. On the other hand, Lebahn declares, from the results of his experiments, that kakodylic acid does possess poisonous properties, and that its toxic symptoms are like those of ordinary arsenical poisoning. Drs. Marshall and Green have repeated these experiments on one cat and three rabbits, using a preparation obtained from a Philadelphia manufacturer. In these experiments vomiting was produced, and considerable disturbance of the health, such as profuse salivation and urination, but in no case did a fatal result occur except in the case of one of the rabbits. In all the cases

the presence of kakodylic acid was determined in the urine, and the garlicky odor due to kakodylic compounds was strongly apparent upon the breath. In the fatal case the whole alimentary tract showed evidences of a severe gastro-enteritis, kakodylic acid was detected in the kidneys, but was not found in the brain. The purity of the substance was then tested, and it was found that it was contaminated with arsenious oxide. The results of the above experiments, therefore, naturally vitiated the value of any conclusions as to the action of kakodylic acid. Experiments were then begun with kakodylic acid obtained from Kahlbaum, of Berlin, which was found to be perfectly pure. This introduced into the stomach, in doses of  $\frac{1}{2}$  gramme repeated several times, produced vomiting and diarrhœa, and evident inflammation of the alimentary tract. The garlicky odor was evident on the breath, and kakodylic acid was in every case found in the urine. In several other instances administration of various-sized doses of this substance produced the same symptoms of profuse salivation, staggering, weakness, vomiting, and diarrhœa, and in one case produced death. The authors' experiments therefore show that kakodylic acid produces symptoms analogous to those of arsenious oxide, though the results are not necessarily fatal. The action of the acid is the same, whether given by the mouth or injected directly into the circulation. The authors conclude, however, from their results that kakodylic is not a poisonous substance in the general acceptance of the word poison. The formula for kakodylic acid is  $(\text{CH}_3)_2\text{As.O.O.H.}$ , and it contains 54.35 per cent. of metallic arsenic, equal to 71.4 per cent. of arsenious oxide.

*THE ETIOLOGY OF TRAUMATIC TETANUS.*

DR. ROSENBACH, at the Congress der Deutschen Gesellschaft für Chirurgie zu Berlin, held at Berlin on April 7, 1886, made some very interesting remarks concerning the etiology of traumatic tetanus. We condense the report of the *Berliner Klinische Wochenschrift* of April 19, 1886, as follows: All efforts to artificially produce traumatic tetanus, or to transfer the affection from man to animal, or *vice versa*, and to thus prove its infectious character, have hitherto been fruitless. The inoculation of blood and pus of tetanic men into animals remained invariably without results; dogs especially appeared

wholly refractory to tetanus. Quite recently, however, Nicolaier found that in certain animals, such as rabbits, guinea-pigs, and mice, the inoculation of ordinary garden earth produced besides malignant oedema an actual tetanus. Almost simultaneously Rosenbach succeeded in transferring tetanus from man to animals. This observer took from a man affected with tetanus, resulting from frost-bites on the feet, a particle of nervous tissue from the neighborhood of the affected parts, and successfully transplanted the material to mice and guinea-pigs. Repeated experiments led also to the preparation of a pure culture, in which he demonstrated as the pathogenetic microbe of tetanus exactly the same minute bristle-like bacillus which Nicolaier had found in garden earth. It is fair to assume that this bacillus gives rise to the production of a poison similar to strychnine, which causes the general convulsions. At all events the infectious nature of tetanus can no longer be positively denied.

#### *SALOL, OR SALICYLIC OF PHENOL.*

This is a new antiseptic that has been discovered by PROFESSOR VON NENCKI, of Berne, Switzerland. It seems destined to take the place of salicylate of sodium, first of all in the treatment of rheumatism, and it may also succeed many of the other antiseptics. The unpleasant taste of the sodium salicylate is known in all hospitals, and it so frequently produces nausea followed by a fainting-fit that for many patients it soon becomes intolerable. The new body, salol, is a white body, slightly greasy to the touch, and having a slight aromatic odor, but no taste. It is almost insoluble in water, but soluble in alcohol.

M. Von Nencki first tried it on animals, and found that all the salol given with the food was found in the urine in the form of urate of salicyl: so that in the organism there was only a simple decomposition without any modification of the composing parts of the salol. Following up his experiments, M. Von Nencki found that it was the pancreatic juice that caused this transformation,—so that it was in the duodenum, and not in the stomach itself, that the decomposition took place; from which fact he explained the absence of nausea, etc., in the administration of the drug. From 6 to 8 grammes of it is now given per day. The urine of the patients becomes almost black, just as though they had taken

carbolic acid itself; but there are no bad consequences from this. Given in all the different rheumatismal affections, it has met with a greater success than the salicylate of sodium, reducing all fever much quicker than the sodium salt. It is also an antipyretic, and it has been tried in phthisis with a result of diminishing the temperature four degrees Centigrade (from 40° to 36°). It is advised to commence in these cases with small doses (0.50 centigramme). Salol would be indicated also in diabetes, as phenol is given. Again, it is given as a local antiseptic in all intestinal catarrhs, and, as Levachoff has demonstrated that salicyl dilutes bile, it may be given in typhoid fever to disinfect the ulcerations, and used also in cholera, and against all intestinal parasites. One of its important uses will most likely be in catarrhs of the bladder. Urine in which it was placed kept without decomposition for over six weeks, and in all cases the patient's urine became completely aseptic. Again, salol is almost insoluble, and its use as an antiseptic in place of iodoform has already given such results that we may be able to get rid of the last-named disagreeable substance and the dangerous corrosive sublimate. If salol does not kill the bacilli, it certainly prevents their development: so it is suitable more than any other known substance to powder wounds with.—*Philadelphia Medical Times*, May 15, 1886.

#### *THE TREATMENT OF THE ROUND GASTRIC ULCER WITH ALBUMINATE OF IRON.*

It is a well-known fact that the affection known as the round or perforating gastric ulcer occurs very frequently in girls and women of the chlorotic type, and that besides other anæmic conditions, especially those following upon a protracted lactation, predispose to the gastric ulcer. Etiologically very different opinions are held; while Virchow and Rokitanski emphasized the narrowness of the lumen of the vessels alongside of a premature fatty degeneration of the vascular walls, other observers accused the abnormal secretion of the gastric juice as the cause of the ulcer.

Still, however different the opinions may be regarding the exact causation of gastric ulceration, all pathologists agree as to the relation existing between the affection and anæmia or chlorosis. The reason that the gastric ulcer, in spite of its unquestioned relation to anæmia, is not treated by preparations of

iron, refers, of course, to the digestive disturbance which this class of medicines is pretty certain to create. Peters (*Blutarmuth und Bleichsucht*, p. 17, Leipzig, Weber), Neuss (*Zeitschrift für Klin. Med.*, 1881, vol. iii. No. 1), and other therapeutists have even published especial papers to prove that iron is positively contraindicated in gastric ulcer.

In view of the foregoing facts, we are rather surprised to find in an article appearing in the *Berl. Klin. Woch.* of April 12, 1886, iron advocated as an effectual remedy of gastric ulcer. The published observations were made by DR. TE GEMPT with the liquor ferri albuminati prepared by Dr. Drees, an apothecary of Bentheim (Hanover).<sup>\*</sup> This drug represents a salt in which the acid, as it were, has been substituted by albumen. It is of a neutral reaction, free from a metallic or astringent taste, well preservable, and highly resorbable.

Gempt had previously ascertained, in an experience of five years, that in chlorosis and anæmia the albuminate solution of iron was the most digestible and reliable of all preparations of iron. And, after having tried the remedy with success in the convalescence following upon gastric ulcer, he began to cautiously administer the drug also in such cases in which the gastric ulcer was still present. The dose used by our author was  $\frac{1}{2}$  to 1 f3 given three times daily to adults, and 5 to 30 drops for children, always to be taken before meal-time. If a diluent be desirable, milk is the best vehicle. The absence of acidity in the drug precludes any injury to the teeth or the mucous membranes of the digestive tract. Hence, Gempt observed in no instance, even after an uninterrupted use of several months, gastric pains or digestive troubles resulting from the remedy.

It requires an especial mentioning that the drug appeared to exercise a direct influence upon hemorrhages from the stomach. The Carlsbad salt was found a useful adjuvant to the albuminate of iron. In conclusion, Gempt makes the important statement that, aside of numerous other affections, this preparation of iron has repeatedly proved a cure in the incipient stages of pulmonary phthisis, the so-called catarrhs of the apex.

If the albuminate of iron should in reality be found to be wholly exempt from the objectionable features of the rest of the preparations of iron, and at the same time to possess

<sup>\*</sup> Merk's liquor ferri albuminati differs from the above in being of an acid reaction, of an astringent taste, and in coagulating milk and chyle.

their medicinal value, the field of practical usefulness of iron would be widely increased.

#### ARSENITE OF BROMINE IN DIABETES MELLITUS.

Following the advice of Dr. Austin Flint, Jr., DR. N. S. DAVIS, JR. (*Journ. of the Amer. Med. Assoc.*, May 8, 1886), has been testing the value of liq. brom. arsenitis, and reports that all the cases in which he has administered it have uniformly been improved. The treatment consisted in directions as regard diet, and the use of the arsenite of bromine in doses of 3 to 5 drops three times daily. Of course it is very doubtful as to whether the improvement in the cases reported by Dr. Davis was due to the medicine which was given or to the restrictions of the diet, since, as is well known, the latter alone, without any medication, will, in many cases, be sufficient to produce decided improvement. Dr. Davis gives the following summary as to restrictions in diet which are advisable:

#### ARTICLES OF FOOD FORBIDDEN.

Bread, cake, pastry of all kinds, and food prepared with flour, cracked wheat, oatmeal, rice.

Potatoes, turnips, beets, beans, corn, carrots.

Prunes, grapes, figs, bananas, pears, apples, preserved fruits.

Liquors of all kinds, whether distilled or fermented.

#### ARTICLES OF FOOD PERMITTED.

Soups, except those rich in vegetables, meat of all kinds, fish, egg, oysters.

Radishes, cucumbers, cresses, celery, lettuce, spinach, cauliflower, cabbage, tomatoes, oyster-plant, onions, string-beans, parsley, mushrooms, salads, pickles, olives, oil.

Lemons, gooseberries, currants, sparingly of raspberries, strawberries, oranges.

Milk, tea and coffee without sugar, but with glycerin in its place if desired.

More or less variation can be allowed from this in mild cases, and in severe cases more rigor may be required, although it is difficult to hold a patient to a diet more rigid than the above.

#### THE RADICAL CURE OF VARICOCELE.

To the large number of operations which have been devised for the cure of varicocele yet another has been added by M. RICHET, of the Hôtel Dieu. It is described in the

*Revue de Chirurgie* for April by M. Picqué, who is disposed to laud it. The vas deferens is first separated from the bundle of veins to be obliterated, and held out of the way by a thread of copper wire passed through the scrotum in an armed needle. The veins and the fold of scrotum over them are then grasped by the blades of forceps heated to a red heat, such as M. Richet uses for the destruction of hemorrhoids. A wound of some size is left, and cicatrization is obtained in about three weeks. M. Picqué argues that excision of the veins is the best of all the many operations for varicocele, but that it should only be undertaken by those who are quite familiar with the aseptic treatment of wounds. In cases where the surgeon is not confident of his ability to keep the wound aseptic, he recommends Richet's operation. We cannot join in such advice. Richet's operation appears, from the description given of it, to be a very rude method of obtaining a result more easily, more quickly, and better obtained by other means.—*Lancet*, May 8, 1886.

#### ON DISINFECTION BY HIGH TEMPERATURES.

In *Virchow's Archiv* (vol. cii. p. 81), WOLF publishes the results obtained with experiments in the use of heat as a disinfecting medium. He used milzbrand-spores (anthrax, splenic fever) dried up on silk threads and placed in mattresses, and observed the action of heat on these organisms. He found that even an influence of  $140^{\circ}$  C. applied for four and a half hours did not suffice to kill the microbes. Quite different results though were obtained by the application of vapor of water, obtained from Schimmel's or Bacon's stove. Wolf formulates his conclusions as follows: 1. For dry objects, watery vapor at the temperature of  $100^{\circ}$  C. is required for one to one and a half hours to obtain a thorough disinfection. 2. For wet objects, a vapor of  $100^{\circ}$  C. is required for two hours. 3. The temperature of the interior portions of the object must be at least  $100^{\circ}$  C. 4. Hot watery vapor of  $100^{\circ}$  C. possesses a higher disinfecting power than hot dry air of a much higher temperature. 5. The objects of disinfection must be destroyed, together with the micro-organisms. 6. The applicability of this method of disinfection, employed alone or in connection with dry air, is a very extensive one.

#### THE BULLOUS FORM OF IODIC ERUPTION.

From a careful study of the bullous form of eruption produced by the administration of iodine, DR. PRINCE A. MORROW draws the following conclusions (*Journ. of Cutaneous and Venereal Diseases*, May, 1886):

1. The bullous form of iodic eruption is comparatively infrequent.
2. It has for its seat of predilection the face, neck, forearms, and hands; exceptionally it may occur upon trunk and lower extremities.
3. There seems to be no definite relation between the amount of the drug ingested and the production of the eruptive accidents; they may follow, indifferently, a single insignificant dose, or may appear only after the long-continued use of large doses.
4. In the former case, the incidental effects of the drug upon the skin depend upon idiosyncrasy, in the latter class of cases the pathogenesis is more obscure.
5. The proneness of this eruption to develop in connection with cardiac and renal disorders would seem to indicate that these conditions stand in the relation of a determining cause, rather than a mere coincidence.

6. The practical inference may be drawn that caution should be observed in the administration of iodide of potassium when these complications are found to exist.

#### THE SURGICAL TREATMENT OF ECZEMA.

BOKHART advocates, in the *Centralblatt für Medicinische Wissenschaften*, 1886, No. 4, the following surgical treatment of circumscribed eczemata of long standing, especially when situated on the trunk or the extremities (except on the hands). The affected portion is to be anæstheticized with the ether spray after the patient has received an injection of morphine; then the part is to be deeply scarified by a double-edged bistoury, making cuts parallel to each other. The bleeding is stopped by compresses, and the part operated upon is rubbed with the officinal potash lye until the thickened epidermis begins to fall off. Then the potash lye is carefully washed off and the part dressed with Hebra's ointment or olive oil, to be replaced by a water dressing after twenty-four hours. After another twenty-four hours, the part operated upon appears like an extensive ulceration,—surface covered with many transplanted particles of skin. The healing process is now

to be favored by a dressing composed of pyrogallic acid or nitrate of silver, which is to be renewed every third day. This mode of treatment prevents relapses and all cicatrization save some few linear marks.

#### THE SURGERY OF THE PANCREAS.

A paper entitled "The Surgery of the Pancreas, as based upon Experiment and Clinical Researches," was read by DR. SENN at the recent meeting of the American Surgical Association (*New York Med. Journ.*, May 15, 1886), from which the following conclusions were drawn :

1. Restoration of the continuity of the pancreatic duct did not take place after complete section of the pancreas.
2. Complete extirpation of the pancreas was invariably followed by death, produced either by the traumatism or gangrene of the duodenum.
3. Partial excision of the pancreas for injury or disease was a feasible and justifiable surgical procedure.
4. Complete obstruction of the pancreatic duct, uncomplicated by pathological conditions of the parenchyma of the organ, never resulted in the formation of a cyst.
5. In simple obstruction of the pancreatic duct the pancreatic juice was removed by absorption.
6. Gradual atrophy of the pancreas from nutritive or degenerative changes of the secreting structure was not incompatible with health.
7. Physiological detachment of any portion of the pancreas was invariably followed by progressive degeneration of the glandular tissue.
8. Extravasation of pancreatic juice into the peritoneal cavity did not produce peritonitis.
9. Crushed or lacerated pancreatic tissue was removed by absorption, provided the site of operation remained aseptic.
10. Complete division of the pancreas by elastic constriction was never followed by restoration of interrupted anatomical continuities.
11. Limited detachment of the mesentery from the duodenum, as required in operations upon the pancreas, was not followed by gangrene of the bowel.
12. In all operations upon the head of the pancreas the physiological attachment of the peripheral portion of the gland should be maintained by preserving the integrity of the main pancreatic duct.
13. Partial excision of the splenic portion of the pancreas was indicated in cases of circumscribed abscess and malignant tumors in all cases where the pathological product could be removed completely without danger of compromising pancreatic digestion, or of inflicting additional injury upon important adjacent organs.
- 14.

Ligation of the pancreas at the point or points of section should precede extirpation as a prophylactic measure against troublesome hemorrhage and the extravasation of pancreatic juice into the peritoneal cavity.

15. The formation of an external pancreatic fistula by abdominal section was indicated in the treatment of cysts, abscess, gangrene, and hemorrhage of the pancreas due to local causes.
16. Abdominal section and lumbar drainage were indicated in cases of abscess or gangrene of the pancreas where it was found impossible to establish an anterior abdominal fistula.
17. Through-drainage was indicated in cases of abscess and gangrene of the pancreas, with diffuse burrowing of pus in the retro-peritoneal space.
18. Removal of an impacted pancreatic calculus in the duodenal extremity of the duct of Wirsung by taxis, or incision and extraction, should be practised in all cases where the common bile-duct was compressed or obstructed by the calculus, and death was threatened by cholæmia.
19. In such cases the principal source of danger, extravasation of bile into the peritoneal cavity, should be avoided by preliminary aspiration of the dilated bile-ducts, accurate closure of the visceral wound with fine silk sutures, and absolute physiological rest of the organs of digestion during the time required for the healing of the visceral wound.

#### COMMUNICATIONS FROM THE DIPHTHERIA WARDS OF THE CHARITÉ.

HENOCH's report on diphtheria, as observed in the wards of the Royal Charité at Berlin (*Charité Annalen*, vol. x. p. 490), embodies much interesting and valuable material.

Diphtheria increases, as appears from the publications of the bureau of statistics, yearly in Berlin, both regarding frequency and malignancy. The same observations could be made at the Charité. From the years 1876-1883 the number of diphtheria patients increased enormously, viz., from twenty-six to one hundred and eighty-three. About two-thirds of all cases belonged to the period between the second and sixth year of life. The mortality rate is most unfavorable in the first three years of life.

Of 319 cases observed, 208 died (an enormous percentage). It must be taken into consideration, however, that, aside from a grave epidemic nature and the naturally unfavorable conditions of a large old hospital, only genuine cases of diphtheria are included in the above statement.

Of the 319 cases, 174 took their course without exceeding the region of the pharynx; of these, 95 were cured and 79 died. This great number of cases with a lethal exit, which did not terminate under symptoms of croup, confirm the frequently-noted fact that the very gravest septic forms of diphtheria show no tendency to extend downward, not even when they attain a duration of seven days and more. One hundred and forty-five cases assumed a croupous nature, and were all operated upon with the exception of 7 cases. These 7 patients perished, while of the 138 operations only 16 (about eleven and a half per cent.) were successful. These figures show that in spite of all dangers which lie in the diphtheritic infection itself, the termination in croup slays the greatest number of victims. Henoch regards the combination of grave septic symptoms with those of croup as the only tenable contraindication to the operation of tracheotomy. Among the causes of death after tracheotomy we find, besides affections of the respiratory organs mentioned, diphtheritic collapse, erysipelas, and (in three instances) convulsions appearing twelve to forty-eight hours after the operation; for these no valid reason could be assigned even after the autopsy. Otitis media was observed only in three cases; rhinitis diphtheriticus, however, in very many instances, even in those which terminated in a cure.

The conjunctiva palpebrarum was but rarely, and only in grave cases, affected. Erythemata occurred in three cases, scarlet fever in many, nephritis in some. When in presence of nephritis symptoms of cardiac weakness set in, injections of camphor, ether, and strychnine were employed, to which, in some instances, Henoch attributed the recovery. In diphtheritic paralysis hypodermic injections of 1 to 4 mg. of strychnine constituted Henoch's routine treatment. Of prolonged diphtheritis Henoch noted also a few cases, one of which lasted over two months up to its recovery.

In conclusion, Henoch declines to admit that any of the vaunted specific measures can be regarded as reliable.

#### PIPERONAL.

This is an aldehyde, corresponding to piperonic acid, obtained as a product in the oxidation of piperina. It occurs in the form of small, white, prismatic scales, possessing a strong odor resembling that of vanilla. A small quantity placed upon the tongue produces a sensation analogous to, but more per-

sistent than, that caused by mint, and it is more irritating to the mucous surfaces than is the latter. It melts at about 125° F., and at a higher temperature volatilizes without leaving any residue. When ignited, the flame and smoke resemble the appearance of burning camphor. It is insoluble in cold water, but in hot water it melts, and looks like drops of oil; it dissolves readily in alcohol and ether. DR. RICCARDO FRIGNANI has made a number of experiments with this substance (*Giornale Internazionale delle Scienze Mediche*, No. 2, 1886), as a result of which he states that it possesses both antipyretic and antiseptic properties. The antipyretic action is not of the most active or energetic kind, yet is sufficient in many cases. It is best given in 15-grain doses, repeated every two hours for three or four times a day, but much larger and more frequent doses are well borne. The most noteworthy disagreeable effects are nausea, eructations, and dryness of the throat. Its antiseptic action, however, the author states, is much more marked, and, since it is innocuous to the system, even when given in doses of  $\frac{3}{8}$  to 1 drachm, he believes that it is deserving of a high rank among drugs of this class.—*New York Med. Rec.*, May 15, 1886.

#### WHICH FOOD-STUFFS ARE DIGESTED MOST EASILY BY THE STOMACH?

To solve the important problem embodied by this heading, BIKFALVI instituted at the Physiological Institute of Klausenburg numerous experiments on dogs by means of artificial digestion. We find the main results of these researches quoted in the *Centralblatt für Med. Wiss.* of February, 1886.

The gelatinous substances, especially the constituents of tendons, appeared to be digested in far greater quantities than pure albumen and organic matters rich in albumen. The experiments on dogs gave the following results. These were digested in two hours:

1. Of raw caseine.....	25	per cent.
2. Of boiled egg.....	41	"
3. Of raw ligam. nuchæ.....	49.5	"
4. Of raw liver.....	52.5	"
5. Of raw kidney.....	55.33	"
6. Of boiled beef.....	58	"
7. Of raw unstripped muscular tissue..	68.5	"
8. Of raw beef.....	79.5	"
9. Of raw hyaline cartilage.....	81	"
10. Of raw fibrin.....	97.5	"
11. Of raw lung.....	99.5	"
12. Of raw tendon.....	95.5	"

The experimenter concluded that the gas-

tric juice of carnivorous animals digests principally the gelatinous substances, and that the digestion of albumen falls chiefly to the action of the pancreatic gland.

**THE TREATMENT OF IRREDUCIBLE  
INGUINAL HERNIA BY ELASTIC  
PRESSURE.**

MR. WM. ELDER reports in the *Brit. Med. Journ.*, May 8, 1886, a case of a man in whom an irreducible inguinal hernia was treated by pads of cotton wool and an elastic bandage, with the result of entirely overcoming the hernia. The case was of a man, aged 56, who had had a small hernia for more than thirty years. He had never worn a truss, or used any means to prevent the hernia from coming down. Recently the difficulty in reducing it had greatly increased, and the tumor had become much enlarged, and finally it became irreducible. The swelling was found to consist chiefly of bowel and omentum, the latter being so much indurated that it felt wherever it was touched as hard as a stone. There was no pain upon pressure, and on palpating the tumor a sort of a gritting sensation was felt as if there was fluid in the sac. The bowel could be reduced, but very little difference could be made in the omentum; reduction under chloroform also failed, and elastic pressure was then applied by means of a padding of salicylic wool and an elastic bandage in the form of a single spica. On removing the pad the next day the hernia was found to be much reduced in size and all the crepitating sensation was gone. The bandage was now kept on for nearly three weeks, resulting in the entire cure of the hernia, which now is entirely reduced, and is readily retained by a truss. Two points appear worthy of notice in this case: first, the efficacy of the elastic pressure in the treatment of irreducible hernia; and second, the method of applying the pressure. The first of these is self-evident, viz., that continued elastic pressure carefully applied must reduce an indurated hernia in size, and by reducing its size must make it more easy to reduce. Secondly, as to the means of applying the pressure. At first the bandage was applied as a single spica in the case above alluded to of Mr. Elder, but it was found that the swelling was more apt to make its way out below the bandage by passing towards the middle line. The bandage was then applied more in the form of a double spica. Mr. Elder began the bandage at the right anterior and superior iliac spine, crossed the abdomen to

below the left trochanter major, then round the thigh and across the perineum to the right groin and right anterior superior iliac spine, where it was pinned to the beginning of the bandage. Then it was wound round the back, above the iliac crests, to keep it from slipping down. He then brought it down over the hernia, on the left side, across the perineum, and round the right thigh, over the front of the abdomen to above the left iliac crest, and round the back to the right anterior superior iliac spine, where the bandage began. He then went on as before, following the same course, but making the bandage above slightly overlap the one below, until he got all the pubic region covered, except a small space in the middle line for the penis. This opening, which always weakens the pressure, must not be too large, otherwise the hernia will tend to escape through it. This bandage had only been once on when the hernia disappeared.

Another point is, that enough wadding must be used in order that, when the bandage is on, it may not pain the patient, and in order that the pressure may be equal all round the hernia. It is not necessary to put the bandage on very tightly, as it gradually becomes tighter the longer it is kept on. The different layers of bandage must be pinned to each other, to prevent them from slipping out of their place.

**ON REVACCINATION.**

In an essay on the revaccination of young individuals, published by DR. JULES BESNIER in the *Revue Mensuelle des Maladies de l'Enfance* (February, 1886), this author establishes the following conclusions:

1. The number of successful revaccinations in young subjects revaccinated for the first time increases with the advancing years, and reaches its maximum at the period of fifteen to twenty years. In adults revaccinations are less frequently successful than in young subjects.

2. Certain diseases favor a successful revaccination at certain periods of life: among these are the affections of the typhoid type. The ordinary eruptive fevers of childhood and the chronic affections of old age have no such influence.

3. In the subjects vaccinated at birth and not revaccinated the predisposition for variola and vaccinia reaches its maximum in the ages of fifteen to twenty, and decreases gradually as age advances.

4. This fact is a stringent reason for the

revaccination of all persons at the stated ages of adolescence.

5. Bovine lymph is, by all means, preferable to human lymph.

6. In absence of an epidemic of variola, the months of March and April (Easter holidays) are most suitable for revaccination of school-children.

#### PAPAÏN.

The Carica papaya (papaïn-tree) has a wide tropical distribution. Its fruit (*Birmingham Med. Review*, May, 1886) resembles a muskmelon in look and structure; it has a strong pungent flavor, and is much relished by children; it is collected in the green state, for, if allowed to ripen on the tree, it becomes bitter. On incising this fruit, a milky juice plentifully exudes, especially if the fruit be in the young green state. This juice may also be scantily obtained from the leaves and young branches.

Papaïn, or papayotin, is the name given indiscriminately to the milky juice, the dried juice (which resembles gum arabic in appearance), and to the ferment-containing powder obtained from this latter by extraction with alcohol. The following notes refer to this powder. Papaïn can be got in any quantity, and is easy of extraction. Its composition, according to Wurtz, is variable. Several analyses gave him this result: C = 46 to 53, N = 14 to 18, H = 6 to 7, S = 2 to 2½, and Ash = 4 to 10.

Wurtz and Bouchut found a butyric ferment in all their samples, but were able to preserve it then in glycerin. It dissolves in less than its own weight of water. A concentrated aqueous solution clouds slightly on boiling, but does not coagulate as does albumen; if left to itself for a few days a similar cloud appears, and the fluid is then seen to be full of vibrios and rods. If pure, it gives no precipitate with corrosive sublimate, basic acetate of lead, nor on boiling. This behavior distinguishes it from peptones and albumens. With nitric and hydrochloric acids a large precipitate occurs, which is readily soluble in excess; phosphoric and acetic acids do not precipitate it; picric acid does so, and the precipitate is not soluble in excess. The powder is white and amorphous, and its aqueous solution has a slightly bitter taste. The actual ferment has not been isolated.

*Physiological Action.*—This is due to the contained ferment, which digests not only muscular fibre but also connective tissue (Brunton).

Wurtz and Bouchut obtained the following results: 1. 1½ grs. in a neutral aqueous solution dissolved 132 out of 155 grs. of moist fibrin in ten hours at 40° C.; there was no swelling of the fibrin previous to its solution. 2. 1½ grs. in a slightly alkaline aqueous solution dissolved 155 grs. of moist fibrin in ten hours at 40° C., except a small residue of dyspeptone; but the filtrate gave a precipitate with acetic and nitric acids, and a cloud appeared on boiling; there was no swelling of the fibrin previous to its solution. 3. 2¼ grs. in a solution acidulated with .2 per cent. HCl made 150 grs. of moist fibrin fluid in fifteen minutes, and dissolved 123 grs. of it in two hours, leaving 27 grs. of finely-divided dyspeptone in suspension; but the filtrate gave a precipitate with nitric acid. Thus papaïn differs from pepsin in its action on proteids in "dissolving them, not only in the presence of a little acid, but even in neutral or alkaline solutions."

Brunton and Wyatt deny that papaïn has any digestive action in an acid solution. Martin found that with .05, .1, and .2 per cent. HCl no digestion took place, for though the solid residue showed slight loss of weight, the filtrates gave the reactions, not of peptones, but of soluble proteids. Saundby found its action enfeebled but not prevented in an acid solution. Lastly, Albrecht declares that hydrochloric acid hastens its action, and states that the officinal preparation in use in Paris hospitals is an acid one. As to its action in an alkaline medium, Saundby says this also causes enfeeblement, but Martin found that in a .25 per cent. solution of sodium carbonate its action was as powerful, if not more so, than in a neutral medium, but that when the alkalinity was raised to .5 or 1 per cent., a weakened action resulted. Rossbach states that its action was stronger at 15° to 20° C. than at 35° to 40° C., while Martin's experience points to the reverse of this.

If we want to complete the conversion of the fibrin into pure peptone, so that nitric acid shall produce no precipitate in the filtrate, the proportion of papaïn to moist fibrin must be as great as three per cent., and the digestion must take place for forty-eight hours at 50° C. The action of the ferment is in no way affected by the rapidly appearing bacteria, for Wurtz showed that when the production of these was prevented by carbolic acid, fibrin was digested as well as ever. Its action on albuminoids resembles that of trypsin more than pepsin. Its first action is one of erosion, and no swelling takes place, while

leucin, and probably tyrosin (Martin), are among the products of digestion. It produces an intermediate product, apparently a globulin; but this seems to resist the change into an alkali-albumen, for no precipitation occurs on neutralizing the alkaline filtrate, only on acidifying this. Milk is first coagulated by it and then precipitated, casein digested afterwards. Its action is more powerful than pepsin and weaker than that of trypsin. Injection into the veins of a rabbit of a small quantity stopped respiration in fifty minutes (Dowdeswell).

**Therapeutic Action.**—The dose of the powder is 5 to 10 grains. It appears to be useful in dyspepsia and gastric catarrh (Brunton), especially one would think in those cases where the mucous membrane is thickly coated. In solution it rapidly dissolves the false membrane of croup, hence in diphtheria the pharynx should be painted with it every five minutes. It has also been used to remove warts, the thickening caused by chronic eczema, and the hypertrophied condition of the palms of the hands. It should be similarly useful in old psoriasis. Some years ago, Mr. Malcolm Morris successfully used it at St. Mary's to remove tubercles of irritation from the hands of the mortuary porter. It painlessly dissolved them away, and its occasional application kept his hands smooth so long as he avoided dead matter. Mr. Cox says it is the remedy *par excellence* in the later stages of "capped elbow" in the horse, when pus or serum has been poured out; that its injection is then much more potent than that of tincture of iodine. Mr. Cox, too, found it a valuable injection into old sinuses. He believes it destroys ("digests") their walls, setting up healthy granulation in their place, which rapidly leads to the complete obliteration of the sinus. This is in the horse, but there seems no reason why it should not be similarly useful in the human subject in cases of chronic bursitis, chronic synovitis, old recurrent hydrocele, etc. It might prove effectual, too, in all those cases where a pyogenic membrane has been produced,—e.g., in a discharging psoas or other chronic abscess, as an injection into the fetid cavities of bronchiectasis, to close up the remains of an old empyema, or to set up healthy action in a case of chronic pleural effusion after removal of the fluid. In the troublesome sinuous tracts which sometimes form the remains of mammary abscess it should prove a valuable injection. Mr. Cox has loosened the attachment of a fibrous tumor in the neck of a horse

by passing a seton through it and keeping the thread soaked in papain juice. It has been recommended to destroy epithelioma. Its action has the great advantages of being painless and unirritating; it is no caustic, nor astringent, nor counter-irritant, but dissolves away the diseased tissues, so giving the underlying structures a chance of showing their healthiness.

#### ON MILK DIGESTION.

REICHMANN (*Archiv für Klinische Medicin*, vol. ix. No. 6) has made some valuable researches on the digestion of milk, which we publish here in condensed form. The milk drank by a healthy young man 20 years of age was subjected to an examination in the various stages of its digestion, and tested for acids, peptones, and parapeptones. Reichmann came to the following conclusions:

1. Three hundred c.c. of raw milk leave the stomach four hours after its ingestion.
2. The actual process of its digestion lasts but three hours.
3. The coagulation of milk takes place five minutes after its ingestion.
4. This coagulation is not caused by an increase in the quantity of acidity, but by the influence of another agent, probably Hammersten's ferment.
5. The maximum of acidity, viz., 0.34 per cent., occurred in all experiments but twice, once after the lapse of forty-five minutes, and the second time after one hour and fifteen minutes.
6. The contents of the stomach attain the maximum of its middle acidity, viz., 0.32 per cent., in one hour and fifteen minutes.
7. The acidity of the contents of the stomach depends at first solely upon lactic acid, later upon lactic acid and muriatic acid together.
8. Muriatic acid presents itself in larger quantities after the lapse of forty-five minutes.
9. The acidity of the gastric contents increases gradually during the first hour and fifteen minutes, and then gradually decreases until the milk has wholly left the stomach.
10. The maximum quantity of peptone occurs at the period between thirty minutes and two hours after the ingestion of milk. Before and after this period peptone occurs only in traces. Parapeptone shows in the beginning of the process of digestion the opposite behavior.

Experiments made on the same individual

with boiled milk led Reichmann to the following conclusions:

1. After the ingestion of 300 c.c. of boiled milk the sour contents leave the stomach in three hours.

2. The actual duration of this digestion lasts two hours and thirty minutes.

3. As to the nature of the acids in the gastric contents, the degree of acidity and its variations, no appreciable differences could be ascertained between the behavior of raw and of boiled milk.

4. In the digestion of boiled milk a more energetic peptonization occurs sooner than in the digestion of raw milk.

5. The caseine clots are much smaller in boiled than in raw milk.

6. The duration of digestion is shorter and the disappearance of the sour contents from the stomach occurs sooner in boiled than in raw milk.

7. After the ingestion of 100 c.c. of boiled milk the sour contents leave the stomach in two hours.

8. The duration of its actual digestion is only forty-five minutes.

9. After the ingestion of 25 c.c. of boiled milk the sour contents leave the stomach in two hours.

10. The duration of digestion of 25 c.c. of boiled milk is only forty-five minutes.

11. After the ingestion of smaller quantities of milk, muriatic acid can be found much sooner in the stomach with the aid of ordinary reactions.

Finally, Reichmann experimented also with alkalinized milk in order to study the action of alkalies on the digestion of milk. All results obtained on the young man experimented upon were later confirmed by researches on nine other healthy persons.

#### THE ACTION OF BICHROMATE OF POTASSIUM.

DR. ALFRED DRYSDALE publishes in the *Med. Press*, April 21 and 28, 1886, an elaborate paper on the sphere of action of bichromate of potassium. When given to animals, 10 grains injected into the jugular vein is capable of producing rapid death in a dog, death being preceded by spasms and retching, followed by motor paralysis. At first the blood-pressure rises, but in a minute or two begins to fall, and continues to do so until death, the slowing of the pulse evidently being due to stimulation of the inhibitory fibres of the vagus. Post-mortem examination shows con-

gestion throughout the large and small intestine, with the membrane reddened or perhaps inflamed. When the drug is given internally in poisonous doses it acts as a violent irritant, produces incessant vomiting and purging of mucus and blood, quick pulse, salivation, rapid emaciation, great weakness, and death within a period of twelve hours to three weeks, sometimes preceded by convulsions. On post-mortem examination, ulcers are found on the mouth and tongue; the mucous membrane of the entire alimentary canal is more or less destroyed, with extensive superficial ulcerations, especially in the stomach. The kidneys are always severely congested. In workmen engaged in the manufactory of this salt very serious symptoms may also be produced. In many of the workers the septum of the nose will have been destroyed by ulceration. In fact, this perforation and destruction of the septum is as characteristic of chrome-workers' disease as is necrosis of the jaw of phosphorus-match makers. The eyes are frequently inflamed, and the alimentary canal disturbed in its functions, while the skin is the seat of a papular eruption, which becomes pustular, and which leaves small dry ulcers, healing with a depressed cicatrix. Used as a remedy, bichromate of potassium may be reasonably hoped to modify pathological processes in tissues which are specifically acted on by the drug, such as the respiratory passages and alimentary canal, the liver, kidneys, skin, and bones. It therefore has been used, and with a certain amount of success, in scrofulous eczema, farcy, and digestive disorders, marasmus, and syphilis. Polypi of the nose, after repeated removal with the forceps, will often yield to the topical application of a snuff composed of 9 parts of sugar of milk to 1 of powdered bichromate of potassium. It also promises success in the treatment of hay asthma, and as a gargle, 2 grains to the ounce of water, with  $\frac{1}{2}$  ounce of glycerin, in acute ulcerated sore throat, as well as in cases of indolent enlargement of the tonsils. When given internally, as in the treatment of certain forms of dyspepsia and chronic intestinal catarrh and in syphilis, the dose should not be more than a  $\frac{1}{4}$  grain daily, though sometimes  $\frac{1}{2}$  grain will be sufficient to produce violent emesis.

#### THE RELATIONS BETWEEN CARDIAC RHYTHM AND BLOOD-PRESSURE.

To ascertain the precise relations existing between the rhythm of the ventricular con-

tractions and the blood-pressure, PROF. BOTKIN, of St. Petersburg, experimented on the frog's ventricle and communicated the obtained results to the *Centralbl. f. Med. Wiss.* (No. 4, 1886). Omitting the purely technical portions of Botkin's communication, we condense his principal conclusions as follows:

1. Twenty-five, forty-five, or sixty minutes pass before the apex—cut out and nourished after the Leipsic method by defibrinated rabbit's blood and two parts of a 0.7 per cent. solution of chloride of sodium—attains a constant working power. If the latter has once been reached, it continues for an hour or more.

2. The variations in the quantity of blood expelled at each ventricular contraction are approximately proportional to the variations in the cardiac rhythm.

3. The power of the cardiac muscle decreases with the acceleration of the rhythm, and increases with the slowing of the latter.

4. An inverse relation appears to exist between the variations in the rhythm of the contractions and the variations in the power of the heart-muscle.

#### EFFECT OF BITTERS ON DIGESTION.

DR. CHELTSOFF, chief of Professor Botkin's clinic, thinks that extracts of the so-called "pure bitters," which are usually prescribed with the view of stimulating the secretion of gastric juice and of aiding digestion, so far from having any beneficial effect of that kind, are absolutely injurious, inasmuch as they retard the digestive functions. He has made a series of experiments with extracts of aurantium, gentian, trifolium, absinthium, calumba, cascarilla, and quassia on (1) gastric digestion and the secretion of gastric juice; (2) pancreatic digestion and the secretion of pancreatic juice; (3) the secretion of bile; (4) fermentation; and (5) nitrogenous metamorphosis. The conclusions at which he arrived were that bitter extracts, even in small doses, interfere with artificial gastric digestion, and also with the gastric digestion of animals, but not to so great an extent. Large doses of bitter extracts diminish the secretion of gastric juice, though small doses effect a slight and transitory increase of it, the digestive power of the fluid being, however, in all cases diminished. Bitter extracts have no effect on the secretion of pancreatic fluid, but they nevertheless retard hypogastric digestion. The action of bitter extracts on the secretion of bile is various; extract of absinthium, extract

of trifolium, and large doses of extract of cetrarin slightly increase it, usually at least, but not invariably; while extract of quassia, extract of calumba, and small doses of extract of cetrarin have no effect at all. Bitter extracts have no antifermentative effect, and do not hinder suppuration. Lastly, assimilation of nitrogenous substances is diminished by the use of these extracts.—*Lancet*, May 15, 1886.

#### TESTING THE DISINFECTING POWER OF COCAINE, CORROSIVE SUBLIMATE, AND CHLORINE-WATER.

In the *Archiv für Augenheilkunde* (vol. xv. p. 295) we find a *résumé* of SCHMIDT-RIMPLER's researches on the comparative disinfectant value of cocaine, corrosive sublimate, and chlorine-water. The experimenter brought the mentioned drugs in contact with the secretions of the lachrymal sac, and then inoculated them into the cornea of forty-eight rabbits.

Using a four per cent. solution of muriate and salicylate of cocaine, he did not note any reduction of the infectious properties of the secretion if the latter had remained for one to three minutes in the solutions. Only after a prolonged contact with the solutions the secretion appeared to have lost some of its infectious nature. This result, however, does not justify the conclusion that cocaine is a disinfectant, properly speaking.

As to the sublimate solution (1 to 5000), the observer found that a short contact of the secretion with the solution did not suffice to remove its capacity of infection; in five to ten minutes, however, this effect could be obtained with certainty.

The chlorine-water showed the promptest effects, and is superior even to the sublimate. Hence, for ophthalmological purposes at least, this drug is to be regarded as the best disinfectant.

#### SOME READILY AVAILABLE TESTS FOR THE IMPURITIES IN WATER.

The most valuable tests for determining the impurities in drinking-water require, as a rule, an amount of apparatus and practice that places them beyond the reach of the practising physician. The estimation of organic carbon and nitrogen, of free and albuminoid ammonia of nitrogen, as nitrates and nitrites, are illustrations of this fact. The presence of nitrites and chlorides is frequently significant of the impurity of water. The nitrogen of organic bodies is converted

in the process of decay into ammonia, and exposed to oxidizing agencies is resolved into nitrous and nitric acids, which combine with bases to form nitrites and nitrates. The former are of especial interest, as a water pure enough for drinking purposes, and not containing more than 1 to 1000 part per 100,000 of nitrous acid, and the presence of three or four times this quantity is sufficient to condemn a water. MR. C. C. HOWARD publishes in the *Sanitarian*, May, 1886, a ready method of determining the presence of nitrous acid in water. The agents which he has found to act most satisfactorily are sulphuric acid and naphthylamine hydrochloride. If water containing not more than 1000 part per 100,000 of nitrous acid be treated with a drop of hydrochloric acid and a drop each of solutions of these reagents, after standing ten or fifteen minutes only the faintest tint of pink will be perceived. If a marked pink be produced, the quantity of nitrites is sufficient to indicate serious contamination. In sewage, and in the water from a few wells, the color was of a deep carmine, and the quantity present 20 to 66 times the limit stated.

Another constituent of importance is chlorine combined with sodium, as sodium chloride or common salt. Since this is found in the fluids of the body, and urine contains 500 parts per 100,000 of chlorine, mixtures of animal excreta with water will increase the quantity of chlorine found therein. Two or three wells have been found in Columbus, Ohio, containing less than 2 parts per 100,000 of chlorine, but the majority contain from 5 to 20 parts per 100,000, while one well in an adjoining town contained more than 50 parts.

The reagents for chlorides are nitric acid and silver nitrate, which produce in water containing chlorides a white precipitate of silver chloride. In water containing 1 or 2 parts of chlorine per 100,000, the precipitate is so slight that it appears as an opalescence, while with 10 or 20 parts a precipitate is produced. The appearance of a marked precipitate indicates the presence of a sufficient quantity of chlorides to justify the rejection of the water.

#### ON THE INFLUENCE OF FOOD ON ANIMAL TEMPERATURE.

PROF. HERING, in Kiew, has studied in detail the question of the influence of ingestion of food on the variations of animal temperature, and has come to some very interesting results, which we find published in the *Centralblatt für Med. Wiss.* (No. 4, 1886). The

observations were made on a man in whom the operation of gastrotomy had been performed on account of œsophageal stenosis.

Hering found a fall in the animal temperature after each meal, and observed that the extent of this fall depended upon the difference in temperature between the ingested food and the stomach.

Ingestion of food and muscular action play, in Hering's estimation, a more important rôle regarding the daily variations of temperature than Liebermeister and other German observers have assumed. Our experimenter found that after the ingestion of hot food the pulse became quicker and soft, respiration more hurried and superficial, and that the temperature fell in the rectum, but rose in the axilla.

On the contrary, after the ingestion of cold food the pulse became slower and hard, respiration slackened, and the temperature fell both in the rectum and the axilla. Vintchgau regards these phenomena as the results of the peptonization of ingested albuminates and the subsequently-produced latent heat, while our observer attributes them to a nervous influence. In his estimation the ingestion of cold food produces a constriction of the blood-vessels as the result of vaso-motoric irritation; in this manner an increase of the arterial pressure is caused, which directs the blood-current from the intestinal tract toward the periphery. Thus the hard pulse and the sinking of the temperature in the stomach find a rational explanation.

The ingestion of cold food, on the contrary, leads to a general paralysis of the vaso-motor nerves, and an afflux of blood to the intestinal tract, while the heart increases its working power in order to retain its influence over the circulation at the usual height.

Alongside of these factors certain other influences require to be considered in the variations of temperature; among these are the periodical ingestion of food, various somatic and psychical actions of the organism, and, finally, time itself, for during the night the temperature is invariably lower than during the day.

#### SANTONATE OF ATROPINE.

Santonate of atropine, a compound of atropine and santonic acid, is recommended by BOMBELLON (*Pharm. Journ. and Trans.*, May 1, 1886) as presenting advantages over any other salt of atropine for ophthalmic purposes, a solution of it being perfectly non-irritating and not liable to fungoid growth. The action

is said to be mild and to resemble that of homatropine; the mydriatic action equals that of atropine sulphate; 1 drop of its solution of 1 centigramme in 20 grammes of water is sufficient to dilate the pupils, the dilatation disappearing in from twelve to twenty-four hours. Santonate of atropine is described as a white, amorphous, non-hygroscopic powder. A dilute solution may be prepared with cold water; a stronger solution requires the aid of a little heat. The solution should be kept in yellow glass bottles to avoid the formation of photosantonin acid under the influence of light, though it is not yet known whether this change would be prejudicial.

#### THE TREATMENT OF HYSTERIA AND NEURASTHENIA.

Therapeutic suggestions coming from America are so invariably received with indifference, or even obstinate opposition, by our German colleagues, that it is gratifying to find in the German medical press the praise of a certain system of treatment as established by an American therapist.

In the *Berliner Klinische Wochenschrift* of April 19, 1886, Dr. BURKART, of Bonn, publishes the results of twenty-one trials with Weir Mitchell's method of treating hysteria and neurasthenia. In a previous paper, which appeared in Volkmann's *Sammlung Klinische Vorträge* (No. 245), this author had first directed the attention of the German profession to the Mitchell treatment of various forms of nervous ataxia and mal-nutrition.

The so-called Weir-Mitchell cure consists, it will be recalled, principally in massage (and faradization) of the muscular system of the body, an enormous supply of readily digestible food, and strict isolation, with rest in bed.

Of the twenty-one cases treated by Burkart (four male and seventeen female patients), nine were little or not at all benefited, while twelve could be discharged as completely cured. Considering that all of these patients had for years suffered from the gravest forms of hysteria and neurasthenia, and that all known remedial resources had previously been tried in vain, the obtained percentage of cures—fifty-seven per cent.—must be regarded as very acceptable.

Burkart gives certain suggestions of practical utility in the Weir-Mitchell cure which will interest those intending to try this treatment at a given opportunity.

In every instance that the Mitchell cure is to be exhibited, Burkart deems it necessary to

carefully consider whether the patient is able to bear with impunity the single requisites of the treatment, as stated above. It is certain, at least, that numerous patients of the neurasthenic type would probably be injured by a rigid execution of this treatment.

Success can, in Burkart's opinion, be looked for only in such patients as are endowed with a considerable energy of will and have firmly determined to assist the physician with their greatest efforts, especially in the direction of nutrition. The patients are, besides, to understand clearly what is intended and what is wanted of them.

In our author's experience, patients in whom a pronounced irritability of the cerebrum existed remained wholly indifferent to the Mitchell treatment. Especially in the case of female patients the required strict isolation will—as Leyden, in a discussion of Mitchell's treatment, had previously pointed out—very often be an injudicious attempt on account of the nervous excitation resulting from it. If the cerebral irritability coexists with or depends upon an existing anæmia, the outlook is more hopeful. In visceral neuralgia Burkart's success was likewise limited: the local pains usually remained, though less pronounced, after all other morbid symptoms had disappeared.

Burkart tried the Mitchell cure also in four instances of sexual neurasthenia,—resulting from a preceding urethral affection or venereal excesses,—but, as could be presumed, with unsatisfactory results; in one instance only was an improvement observed.

The Mitchell cure, exhibited under the precaution of strict individualization, deserves, in Burkart's opinion, the reputation it enjoys in America, and is well worthy of further trials.

#### LIGATURE OF THE LARGER ARTERIES IN THEIR CONTINUITY.

At a recent meeting of the Royal Medical and Chirurgical Society (*Lancet*, May 15, 1886), MR. BALLANCE and MR. W. EDMUNDS communicated the results of an experimental inquiry on the ligature of the larger arteries in their continuity. The experiments were made by the permission of Prof. Birch-Hirschfeld at Leipsic. The object of the paper was to show that in the ligature of a large artery in its continuity (1) it was neither necessary nor advisable to tie the ligature so tightly as to rupture the coats of the vessel; (2) the lumen of the vessel must be completely or almost completely obliterated; (3) the round ligature,

of small size and possessed of certain qualities, was the best. The authors commenced with a short historical sketch. They then stated the reasons which led them to perform the experiments which formed the basis of the paper. Nineteen carotid arteries of sheep and horses were ligatured, some with catgut and others with kangaroo tendon, and the result in each case was given. The animals were killed and the vessels removed from nine hours to seventy-three days after ligature. The general results of the operations were summarized, and the best material for ligature and the function of the clot discussed. Certain objections which might be raised were considered, and, in conclusion, the authors recommended for the operation of ligation in continuity (1) aseptic precautions; (2) the small round absorbable ligature; (3) the maintenance of the integrity of the arterial wall. The paper was illustrated by macroscopic and microscopic preparations, and by drawings. It was seen in the preparations that the inner coats, even where included in the ligature, were alive and apparently of unimpaired vitality; that, although the tunics were unruptured, a plastic effusion had taken place, which in the arteries removed latest was developing into connective tissue, permanently occluding the vessel. With respect to the ligatures, leucocytes were thrown out round them, and gradually caused their absorption. In the case of kangaroo tendon, the absorption took place only from the surface; but with catgut the leucocytes insinuated themselves along the crevices formed by the twisting of the gut, and the ligature became absorbed more rapidly. The durability of catgut seemed to vary in different specimens; but it was thought that in wounds that healed by first intention good catgut held for about a month, and kangaroo tendon for two. In the three carotids of horses in which alone suppuration had occurred, it was proved that catgut was rapidly becoming absorbed in fourteen days, and had completely disappeared in fifty-one days, and that kangaroo tendon was but little altered in ten days.

MR. BARWELL agreed largely with the conclusions of the authors, especially as to the undesirability of rupturing the internal coats. Whether it was preferable to use the round rather than the flat ligature for the purpose was a matter on which he joined issue with them. A small round ligature would more readily tear the inner coat. We ought not to lose sight of the different states in which the vessels are: some were

tightly stretched, and others in a lax state. He had formed his own conclusions as to the results of experiments on dead subjects and living animals. He considered that a flat ligature could lie smoothly, and the knot was not clumsy, though of large size, which he regarded as an advantage, for a small knot of catgut was more liable to set up ulceration and perforation, as in a case of innominate aneurism in which Mr. Bennett May ligatured the carotid artery. A large knot obviated that difficulty of ulceration and perforation altogether. Again, a small knot was not sufficiently broad to resist the impulse of the blood-current. A good-sized clot in the vessel was also advantageous as a check to the force of the blood-current. There was further a general unreliability in carbolized catgut, which at least introduced an element of undesirable uncertainty, for it might be absorbed in a very short time.

MR. SCOVELL SAVORY considered that the authors had collected an interesting series of facts, but he could hardly follow them in their conclusions that it was neither necessary nor advisable to rupture the inner coats. He failed to see how their experiments proved that it was not advisable; they had made no "check" experiments; their paper abounded in *ex-parte* statements; the experiments had all been done in one way. If check experiments had been made they might have had facts which would justify their conclusions. Experimental investigations tended to show that the arterial system of animals differed very much from that of man; it was much more difficult to excite septic processes in animals, as Dr. Jones long ago proved. It was owing to the greater number of mishaps where animal ligatures were employed that made many surgeons hesitate still to employ them in preference to silk ligatures.

MR. T. HOLMES also congratulated the authors on their industry and on the interest of the facts collated in the paper; but he hesitated to accept their main conclusions. He would not like to trust experiments on animals in guiding him as to what to do in the human subject. In one of Mr. Barwell's cases of ligature without rupture of the internal coats the vessel became pervious not long after the operation. He had been content with the practice at St. George's of division of the internal coats. In one instance Mr. Pick ligatured the femoral for popliteal aneurism without rupturing the internal tunics, and pulsation recurred, though he felt bound

to add that the vessel was afterwards tied lower down as tightly as possible, and then pulsation recurred. In truth, a long period of experience on human subjects would be necessary before we could accept the conclusions of the authors. In division of the internal tunics a greater amount of lymph was thrown out, which in itself would appear to be an advantage, and he asked whether there was a corresponding disadvantage in this excess of lymph. He could not but think that experiments on animals were not entirely satisfactory. It was at one time thought that a powerful barrier to the restoration of the circulation would be found in the employment of silver ligatures, which would produce no irritation. But in one instance in the practice of Brodhurst secondary hemorrhage occurred. In a paper read before the Pathological Society, Mr. Pick also showed how the artery could be occluded without dividing the internal coats by ligatures, which at the end of three weeks had not caused ulceration.

MR. C. DENT had been engaged in a similar inquiry on the femoral arteries of sheep, using kangaroo tendon prepared in chromic acid, the internal tunics being completely ruptured. He considered that rupture of the tunics made the operation certain and was a better surgical practice. In one case pus formed around the ligature, which had not been rendered sufficiently septic. In none of the cases did secondary hemorrhage occur.

MR. BARWELL explained that he used the ox aorta ligature in the case referred to by Mr. Holmes, and the failure was purely an error of manipulation, and had nothing to do with the nature of the material employed.

MR. W. EDMUNDS, in reply, pointed out that even in tying a flat ligature the knot was liable to present an angular projection, and so Mr. Barwell's argument that with a flat ligature the adhesion between the coats was favored need not always hold good.

MR. BALLANCE, in reply, admitted that more skill was necessary to apply a round ligature so as not to rupture the internal coats, but a very little practice in the post-mortem room would suffice to show how to occlude the lumen of the vessel, so that no water would be syringed through. On examination it would be found that no damage to the tunics had been done. A long piece of artery was occluded even with a small ligature, as the specimens on the table showed. Dr. Jones's classical work was referred to by Mr. Savory, but at that time it was thought that the question of rupture of the coats had been

threshed out. His object and that of Mr. Edmunds was to present a series of observations showing what happened when the coats were not ruptured.

Perhaps the chief interest of this paper lies in the careful and extensive pathological investigation, but it has an evident direct bearing on surgical practice which could not fail to excite the interest and close attention of the surgeons present. The chief contention of the authors was that it is "neither necessary nor advisable" to ligature the vessel so tightly as to rupture the coats. It is necessary, however, to obliterate as nearly as possible the lumen of the artery. The object aimed at should be the excitement of just sufficient damage to cause a chronic or subacute arteritis, which leads to permanent occlusion of the vessel. The internal coats should not be ruptured for fear of opening up channels for septic absorption, and with a view to preventing such a degree of damage as would be followed by ulceration and subsequent danger from secondary hemorrhage. If it were easily possible to excite just sufficient inflammation to secure the object in view by the means advocated, considerable progress would be made in arterial surgery. Mr. Savory, Mr. Holmes, and others appeared to doubt the possibility of obtaining the desired end by the method recommended when applied to the human subject. An examination of the specimens, both macroscopically and microscopically, is sufficient to convince the most sceptical that the means employed in sheep and horses were adequate to the end in view. But here comes the rub. Can we argue from animal to man—from the arteries of sheep and horses to those of human beings? Theoretically we do not perceive why this should be impossible; but even the authors of the paper would probably admit that this is a question which must be submitted to the test of a prolonged experience in the operating-theatre and wards of hospitals for human beings. One point on which the authors commented was the undesirability of attempting to rupture the internal coats of diseased arteries when these have to be deligated in their continuity. Every surgeon must feel the immense importance of the question; for assuredly a benefit of no mean order would be conferred on individuals with diseased arteries if a ligature could be so applied as to be sufficient to incite an inflammatory process adequate to effect the occlusion of the lumen of a diseased artery, and without being so firmly tied as to rupture its internal coats.

## OBSERVATIONS ON THE NEW ANTI-PYRETICS.

In spite of the great number of clinical observations on the comparative value of the antipyretics recently introduced into the practice of medicine, additional reliable data concerning their employment are certain to receive attention.

DR. PAVAY, chief of the Presburg Hospital, publishes in the *Wiener Medizinische Wochenschrift*, 1886, No. 8, an essay on the subject of antipyretics, from which we abstract some of the more interesting topics.

Antipyrin is at present acknowledged to surpass, in certain affections at least, quinine and salicylic acid. It fully meets the requirements of a practical antipyretic; for there is no acute febrile affection of which antipyrin is not able to reduce the temperature with certainty. The extent and duration of the reduction of temperature caused by antipyrin is directly proportional to the quantity of the drug employed. Secondary symptoms cannot be said to be wholly absent after the use of antipyrin, but they are decidedly milder than in the case of quinine and salicylic acid.

There is a considerable variance of opinion as to the proper dose of the drug. Ziemssen, for example, in a case of pneumonia or typhoid fever, orders daily doses of 3 dr., while other clinicians prescribe only 1 to 2 dr. *pro die*. Pavay regards the latter dose as quite sufficient, and denounces the fashion of German physicians to exhibit the antipyretic remedies only in very large doses. Pavay has employed antipyrin with satisfactory results in typhoid fever, erysipelas, puerperal fever, phthisis, pneumonia, acute articular rheumatism, variola; in fact, in almost every febrile affection. The quickness and certainty in its action are especial recommendations for its employment.

The temperature lowered by antipyrin rises in most instances slowly, without producing any rigors. The sweat caused by antipyrin is always less excessive than that produced by salicylic acid or thallin; in phthisical subjects it produces the greatest sweats. The fact of a measles-like eruption following after the use of antipyrin is well known.\* The drug may also be given hypodermically or as an enema. If it should occasion diarrhoea when given *per os*, extract of opium may be conveniently combined with it.

Pavay made also comparative experiments with quinine, salicylate of sodium, and antipyrin, by exhibiting all three drugs to the same patient (phthisis). He found that the effects were identical if of quinine 15 to 22 grains, of antipyrin 37 grains, and of salicylate of sodium 45 grains, were used. In phthisical subjects, however, quinine and salicylate of sodium are both contraindicated, the former on account of the "chininism" (cinchonization), the latter on account of the excessive sweat which it produces even when combined with atropine.

Antipyrin is in one to two hours after its ingestion recoverable from the urine; in presence of a solution of chloride of iron the urine assumes a red-brown color.

In conclusion, Pavay mentions thallin, resorcin, hydrochinon, chinolin, kafrin, resorzoate of sodium, veratrine, and digitalis as antipyretic remedies, but regards them all as little prompt and reliable. Besides, nearly all cause such untoward after-effects that for this reason alone their employment is not advisable. Thus, chinolin causes vomiting, resorcin and hydrochinon great nervous excitation, and kafrin a very unpleasant sensation in the face and nose, and besides that vomiting, cyanosis, and finally collapse.

## THE PRESERVATION OF SOLUTIONS FOR HYPODERMIC USE.

An ingenious method of preparing and preserving solutions for hypodermic injection, according to the *Pharm. Journ. and Trans.*, May 1, 1886, has been devised by M. LIMOUSIN. It consists in first sterilizing small glass globules, of rather more than a cubic centimetre capacity, and having a long drawn out neck, by heating them in a stove to about 200° C. These are filled with the solution, either by introducing the end of the neck of the heated globule into the cold liquid, or by injecting the hot liquid by means of a finely-pointed syringe. The end of the neck is then sealed in a flame. The solutions are prepared hot, with water that has been boiled and previously filtered through a Chamberland filter. M. Limousin rarely uses distilled water, as he considers the salts present in ordinary water retard the invasion of fungi. Under these conditions he states that solutions of ergot and hydrochlorate of morphine have remained intact for upwards of a year. When required for use, the fine neck of the globule is broken off, and a sufficiency of the liquid taken up in a syringe direct.

\* At a visit to the General Hospital of Hamburg, Dr. Wolf presented a phthisical patient, in whom antipyrin had produced a genuine scarlet-fever rash.

### ON AMBLYOPIA PRODUCED BY INTOXICATIONS.

DR. BERGMEISTER held, in the Wissenschaftliche Versammlungen at Vienna (*vide Wiener Med. Woch.*, No. 8, 1886), a discourse on the interferences of vision produced by the action of poisons. There is an acute intoxication-amblyopia as resulting from the ingestion of certain medicines, such as quinine, salicylate of sodium, and santonine, though the affection is more frequent in its chronic form. Among the causes of the chronic intoxication-amblyopia are: 1, visual interferences resulting from handling toxic agents, such as lead and sulphide of carbon; 2, the results of abuse of tobacco, alcohol, opium, morphine, and hashish; 3, the effects of snake-bites (blindness).

Other intoxications cause simply interferences of accommodation, without preventing an amaurosis; to this category belong intoxications produced by anilin, ether, aconite, Calabar bean, chloral, atropine, duboisine, and the poison generated in the sausage. The prognosis of both the alcohol and the tobacco amblyopia is not unfavorable.

### HOW TO DETECT ACETONE IN URINE.

It is stated by MONS. P. CHAUTARD (*Lancet*, May 15, 1886) that the presence of acetone in urine or pathological liquids may be readily detected by adding a drop of an aqueous solution of magenta decolorized by sulphurous acid to the suspected liquid, when, if acetone is present, a violet color is produced, the intensity of which is proportional to the amount present. In dilute solutions the coloration does not appear until after four or five minutes; if the amount of acetone is very minute, the urine or other liquid may be distilled, the first portion that comes over being examined. In this way a very minute proportion of acetone may be detected.

### ACTION OF CONIINUM HYDROBROMATUM.

SCHULZ and PEIPER report in the *Archiv für Experimentelle Pathol.*, vol. xx. p. 149, their experiments with hydrobromate of coniine. The principal question to decide was whether the drug, employed in a watery solution, was capable to suppress convulsions artificially produced,—for example, those caused by brucine. They found that the respiration in the animals treated with the coniine salt became again deep and easy, and that there

was no noticeable muscular spasm. The convulsions subsequent to the brucine-ingestion could be both avoided when coniine was administered previously, and removed when given afterwards. In view of the anticonvulsive action of the hydrobromate of coniine, the observers regard the drug suitable for practical trials.

## Reviews.

DISEASES OF THE DIGESTIVE ORGANS IN INFANCY AND CHILDHOOD, WITH CHAPTERS ON THE INVESTIGATION OF DISEASE, AND ON THE GENERAL MANAGEMENT OF CHILDREN. By Louis Starr, M.D., Clinical Professor of Diseases of Children in Hospital of University of Pennsylvania; Physician to Children's Hospital, etc. With colored plate and other illustrations. Philadelphia: P. Blakiston, Son & Co., 1886.

The scope of this book, as indicated by its title, might have served to restrict the author somewhat, but he has taken it in its widest significance. In his introduction he treats of the investigation of disease, and his directions are pertinent and often original. The section on "Inspecting the Child" is especially to be noted as containing very valuable matter; nothing seems to have been omitted, while the language is graphic, and contains here and there touches of that genius for description which marks the book throughout. In looking through the early pages we see (p. 29) "incessant unappeasable crying is due to one of two causes, earache or hunger," and would suggest in passing two more, thirst and a misplaced pin, and also that earache can be diagnosticated from hunger as well, in many cases, by traction or pressure on certain neighboring parts as by putting the child to the breast or bottle, as the author advises, since food seems a sort of infant solace for all imaginable aches and pains.

Under "Affections of the Mouth and Throat" the author includes catarrhal, aphthous, ulcerative, and gangrenous stomatitis. We feel sure that eventually ulcerative stomatitis will be traced to an origin in some disease affecting the cow and its milk, but at present the author agrees with most authorities in denying it a specific contagium, nor do we think that the causes he enumerates—decayed teeth, want of cleanliness in the mouth, and the too free administration of lead, phosphorus, and mercury—have anything to do with the causation of the disease as he describes it. It will be found, we think, on careful investigation, that in a large majority of

cases the child affected has been recently—*i.e.*, within two weeks—put upon a diet of cow's milk, or upon a different milk-supply, or if previously so fed, that the scalding of the milk has been omitted in that period. It will also be found that the disease follows milk from certain sources of supply, and can attack adults when they are extensive drinkers of such milk, while decayed teeth are only an occasional accompaniment of the disorder, and phosphorus causes its own well-known necrosis, and mercury mercurial stomatitis.

The author lays great stress upon the factor of breath, but it bears no comparison in quality or quantity to that of mercurial disease. In the chapter on thrush the author seems to have overlooked the value of hyposulphite of sodium internally administered, while as a wash he partially recognizes its value, but the reviewer has seen much apparent benefit from its internal administration in 3- to 5-drop doses of the saturated solution, which same solution is a necessity in local application. Anything weaker, as, for instance, the author's 10-grain solution, will generally fail and throw discredit upon the remedy.

Under "Dentition," in regard to eczema of the scalp and face, we find "there can be no question as to the propriety of healing eczema as quickly as possible." Now we think there is some question which concerns the remedies used; we would rather say, eczema should be cured as quickly as ordinary and safe measures would do it. The reviewer has often in times past chased eczema by local applications, generally mercurial, from face to scalp, to eye, to ear, to violent intestinal disturbance, and has been only too glad, after nearly losing his case, to find the dangerous symptoms disappear with the reappearance of the old facial trouble; so that we would say, if any internal medication, any alteration of diet, any assistance to the digestive process and general improvement of health be of service to the local condition, it is called for, but to heal the eruption "as quickly as possible" may involve measures detrimental to life itself.

In nervous disturbances at the time of teething the book advocates the use of the gum lancet, but urges it at an earlier period than many would consider necessary. In chronic hypertrophy of the tonsils the author recommends the use of the solid stick of nitrate of silver. This is so dubious a procedure that we are sorry to see it advocated. As a preliminary to excision it may be employed, for burned tonsils will never sponta-

neously disappear, and will inevitably need the knife. The tendency of the day is towards milder measures, and reserves the knife when these fail. By drying the tonsils carefully with absorbent cotton and painting systematically with iodine twice or thrice weekly, marked absorption will generally take place. Iodine internally will facilitate it, but better still the steady, persevering employment—either by gargling or by brush—of bromide of potassium and ergot. Under the use of this the blanched tonsils soon lose their redundant tissue, and if near puberty—if not already by injudicious management a mass of cicatricial tissue—the glands will diminish to their normal size.

The author, in "Affections of the Stomach and Intestines," gives us his views concerning infant feeding in the earlier months. Recognizing, as do all, that improper and unnatural food is the great provocative of infantile intestinal disorders, the aim of the numberless "infant foods" is to meet the difficulty. The author's favorite food seems to be composed of milk and cream, milk-sugar, and water, in varying proportions. This may answer perfectly with children who would thrive on cow's milk, but for the difficult cases, with feeble digestion, there is still too much casein,—not perhaps too much in theory,—but the casein of cow's milk and that of human milk behave differently under the same circumstances. The reviewer has been satisfied for many years with a formula of cream one part to water five parts, increased to four parts water as the child ages. Average cream contains enough milk—*i.e.*, casein—for the child to manage. With this formula there is no difficulty in raising delicate children in good condition to the age when farinaceous foods can be readily digested. The author's use of milk-sugar and Mellin's food, which latter can only practically serve the purpose of sweetening, seems unnecessary and burdensome. Milk-sugar is by no means always a pure article, or always accessible, and pure cane-sugar in small quantity has never been proved deleterious. While condemning farinaceous foods in the early months, the author, following an eminent authority, recommends barley-water as a diluent—but barley is somewhat farinaceous—and weak veal broth, a favorite with the British writers on this subject, but liable to all the objections to which veal is open, and by no means easier of digestion than the broth of grown animals.

Whether it be worth while to elaborate into a separate existence the condition met with in

gastro-intestinal catarrh, which the author describes as "mucous disease," is a question. For its relief we have given us a special diet table, from which farinaceous food is omitted as far as possible. The recommendation of 20 drops of tincture of myrrh in this condition, given after meals, might in many cases be altered to before meals. In connection with this symptom we find a description of stomach-cough which would make Mrs. Gamp's mouth water. This cough the author describes as a common accompaniment of "mucous disease," and remarks upon its perplexing similarity to whooping-cough, and upon the fact that ordinary remedial measures are useless. We notice in the formulæ given for its relief the well-known prescription for whooping-cough of the late Dr. John Forsyth Meigs, consisting of alum, belladonna, and syrup of ginger. Can it be possible that those habitually using it for pertussis with so much success have been by an error of diagnosis prescribing for and relieving "stomach-cough" all the while?

For chronic entero-colitis we have more diet tables, and good use is made of raw oysters and junket as articles of food. From the number of formulæ appended to the chapter the reader should be at no loss in prescription-writing, especially as the author has taken great pains to discriminate as to the conditions requiring the special use of each one. Perhaps he has erred in the too minute subdivision of his subject, it being wellnigh impossible to rigidly class many cases of intestinal disease, and a slight glance at his pages will show that at least three separately-described conditions demand much the same diet and remedies. Cholera infantum has received but slight attention, and is regarded by the author as very formidable. "In the fortunate cases in which this plan is successful," he says, as though somewhat hopeless about the result; yet we think many will agree that the class of cases to which the author restricts the name, cases previously in health, uncomplicated, make better and more frequent recoveries than the cases of acute entero-colitis, which so readily become chronic. There is, too, no recognition of the value of carbolic acid and creasote in the management of the vomiting of cholera infantum.

Acute dysentery, which is at last admitted as a possibility in infants, receives much attention, but there is no mention of the benefits arising from medicine administered by suppository, or of the value of large demulcent enemata, or the administration of salines or

ipeacac. The difficult question of "Habitual Constipation" has been carefully treated. Cascara, perhaps the best remedy for the condition, is mentioned nearly at the end of the text. And senna has not received enough consideration, since, in the truly habitual constitutional cases of constipation, senna alone, or in any of its combinations, of compound liquorice-powder, confections and laxatives, will immediately solve the difficulty.

The chapters on simple atrophy, typhlitis and perityphlitis, and intussusception are excellent, and worth a careful study. True congestion of the liver the author thinks a quite common disease of children from four years upward. There must be "enlargement of the organ, with pain and tenderness, jaundice, and clay-colored, offensive stools." Fatty infiltration, fatty degeneration, amyloid and syphilitic liver, are minutely described, and one case of abscess of the liver in an infant is given in detail. Acute tubercular peritonitis and ascites conclude Part II., and Part III. is devoted to the "General Management of Children." While the author believes in the value to the child of the mother's breast, in regard to wet-nursing his words have a singular sound, when, after enumerating the advantages and disadvantages of a wet-nurse, we read, "for these reasons it is preferable in the majority of instances to trust to careful bottle-feeding." And, again, "there can be no doubt . . . that, taking the average, infants properly brought up by hand are better developed and enjoy more perfect health than those completely breast-fed." Condensed milk is very properly condemned as a sole diet. The process of peptonizing milk is minutely described, and many formulæ for milk-food suited to different ages are given, as well as diet tables. Taken as a whole, this book shows a marked individuality, where individuality is difficult; it is thoroughly practical in its aim; its tone is good; it is not overburdened with technicalities or the labored language of the schools, but speaks the thought of the true practitioner, whose aim is rather to cure than teach. While here and there one may descant a little, the pages are few on which one can find anything doubtful, or search in vain for anything indispensable. E. W. W.

THE STUDENT'S MANUAL OF VENEREAL DISEASES.  
By Berkeley Hill, M.D., and Arthur Cooper, M.D.  
Fourth Edition.

This small volume is evidently in demand, having reached a fourth edition, and we hesi-

tate somewhat to give our opinion in the face of such success ; but it is always a problem to us why this class of medical books are successful. They certainly cannot satisfy one who is desirous to study the diseases of which they treat, and to turn to them for information in order to treat the diseases which they discuss is generally useless. That the above work is not good we cannot for a moment think. It is, indeed, very good for what it claims to be, and as an outline of the larger and most excellent work upon the same subject by the same authors, it could not be better.

LOCAL ANÆSTHESIA IN GENERAL MEDICINE AND SURGERY, BEING A PRACTICAL APPLICATION OF THE AUTHOR'S RECENT DISCOVERIES. By J. Leonard Corning, M.D.

New York : D. Appleton & Co., 1886.

Dr. Corning, unlike many writers of the day, enjoys the advantage of a thorough knowledge of his subject. He will be remembered as the author of "Brain Rest" and "Brain Exhaustion," and as the discoverer of the "carotid compressor," a means of alleviating suffering and procuring sleep, singularly unappreciated by the world. In fact, the human race, depraved as it is, was not ready for the carotid compressor: it was born, like the photograph, before its time. Yet even now it may be pursuing in secret its insidious work. Acute but unprincipled minds may have silently recognized its value, and by this time it may have lulled to perpetual sleep many a political opponent and a domestic enemy, but certain it is that the instrument which promised so much, which made the miser count in secret his spare cash, and the mother-in-law tremble with unspoken fear, is seldom mentioned to-day. It is not on sale at the nearest drug-store, nor is it carried in the pocket of the enterprising physician. Something very like it is extensively employed, under a more forbidding name, in some parts of Europe, for purposes of capital punishment, but elsewhere it seems to have made but little headway.

Dr. Corning now claims to have made another discovery. In the present volume he gives us an account of cocaine from its discovery up to his own time, up to the occurrence of Dr. Corning, so to speak. This drug had been previously used locally by others in many operations, and a considerable number of facts had been already accumulated ; but to make local anæsthesia complete and prolonged, so much of the drug was

necessarily employed as to render the patient liable to subsequent danger from the impression upon the system at large. Dr. Corning tells us that his own discovery was by no means accidental ; but, like the discoveries of Columbus, Watt, Prof. Bell, and other true discoverers, it was "the direct outgrowth of a chain of deductive reasoning." An "outgrowth of a chain" is something truly unusual. Even Columbus and the other worthies never found anything like that. This "outgrowth," or discovery, consists in a plan for confining or retaining the cocaine after its hypodermic injection within limited areas, and is done by mechanical means. In short, the mechanical genius which conceived and gave to a thankless world the carotid compressor, found but little difficulty in solving this problem.

For a limb the bandage of Esmarch is applied up to the desired point ; then, after injecting the cocaine, and waiting a few moments for a little diffusion to take place, the bandage is continued upward, leaving the injected area uncovered, and the subsequent procedure is the usual one with the Esmarch bandage. This plan Dr. Corning has extended and modified to meet almost all imaginable conditions, and he describes and depicts his methods and his instruments and bandages *in situ*. We are also introduced to an anæsthetic trochar, tourniquet, and clamp, to his own hypodermic syringe, and very proud we are to make its acquaintance. He shows us his method of mapping out the veins, and his anæsthetic bistoury, an æsthesiometric probe. For other localities than limbs he uses incarcerating rings and hæmostatic clamps. All these are necessary if the reader would practise "Corningism" successfully ; and so valuable a method is it that the hip-joint can be excised under its influence, and bone surgery generally is possible. In fractures and dislocations Dr. Corning also resorts to it.

The author appends some experimental observations of his own on the "Influence of Cocaine upon the Healing of Wounds," "Spinal Anæsthesia and Coca Medication of the Cord," and an appendix, detailing the successful employment of Corningism by others.

This discovery will doubtless prove of great value, and by no means deserves to be classed with the "carotid compressor." Man now, thanks in part at least to Dr. Corning, seems to be able to render himself superior to pain, while preserving his intellectual facul-

ties unimpaired, even momentarily, and what wonderful uses do we foresee for this process in the future! By its means the ingenious physician may render the wife-beater proof against even the lash of the Delaware sheriff, and, should religious persecution ever again arise, may enable the martyr to meet the flames even hilariously, if only thoroughly Corningized, or, as the word will probably be abbreviated, Corned. The tender-hearted anarchist will anæsthetize his capitalist, hunger and cold will be banished by chewing coca-leaves, and coca, as a true tree of life, assisted by the hypodermic needle, the æsthesiometric probe, and incarcerating rings, will make earth once more a paradise.

A SYSTEM OF PRACTICAL MEDICINE BY AMERICAN AUTHORS. Edited by Wm. Pepper, M.D., LL.D., etc., assisted by Louis Starr, M.D. Vol. IV. Philadelphia: Lea Bros., 1886.

This volume is devoted to diseases of the genito-urinary system, the muscular system, diseases of the skin, and medical ophthalmology and otology. It embraces subjects not always discussed in "systems of medicine," and, where the topics pertain rather to the domain of surgery, the aim of the writer is often to take rather a medical than a surgical view of the field.

The gynæcological portion of the book is quite full, and embraces articles from many eminent specialists, and forms a section of great interest and value. While it would be invidious to draw too many comparisons, and where so many valuable articles are brought together, we confess to being particularly impressed by Dr. Ed. L. Key's excellent chapter on "Diseases of the Male Bladder," Dr. Ed. C. Dudley's "Displacements of the Uterus," Dr. J. C. Reeves's "Disorders of the Uterine Functions," Dr. Byford's three articles on "Fibrous Tumors," "Sarcoma and Carcinoma of the Uterus," and Dr. Wm. Goodell's "Diseases of the Ovaries and Oviducts." Dr. Alexander J. C. Skene, in "Organic Diseases of the Bladder," seems still almost as heedless of the value of belladonna and its alkaloid in these affections as when he wrote his "Diseases of the Bladder and Urethra in Women" some years ago. Dr. Geo. J. Engelmann gives us an excellent chapter on "Abortion," going into rather than over the many intricate questions of diagrams and management so familiar to those who have made family practice a business. These articles form an invaluable col-

lection of monographs upon subjects of kindred interest, and have an entirely unique value. A vast mass of literature would require searching and sifting to bring together all the matter here prescribed in but a portion of a single volume.

The section on "Diseases of the Muscular System" contains Dr. J. C. Wilson's suggestive and practical article on "Myalgia," Dr. Jas. Tyson's "Progressive Muscular Atrophy," and Dr. Mary Putnam Jacoby's "Pseudo-Hypertrophic Paralysis."

The section on "Diseases of the Skin," by Drs. Louis A. Duhring and Henry W. Stelwagon, gives us in moderate compass the most recent views and approved methods of treatment.

Perhaps the most striking and erudite article in the book is that on "Medical Ophthalmology," by Dr. Wm. F. Norris, covering about fifty pages. It has demanded for its production not only a great amount of general and special medical knowledge, but that rare faculty which enables a writer to see the general dependency and intimate relationship of many topics, by no means kindred, to the superficial and merely systematic observer. The aim of the article is "to give an account of the eye-symptoms which may be seen in the course of diseases of the general system and in connection with the pathological conditions of the various organs of the body." Carrying out this aim, Dr. Norris has produced a truly invaluable article.

"Medical Otology" concludes the volume, and is written by Dr. George Strawbridge. While more limited in its scope than the preceding article, it will prove of great use to the practitioner.

Of many articles in this volume we have made no mention. Nearly all will be found to be able presentations of the subjects they discuss. Some topics of great importance are hastily treated, and the captious will find much to criticise; but, as a whole, we consider vol. iv. as the most valuable of the series so far issued.

INSANITY AND ITS TREATMENT. LECTURES ON THE TREATMENT, MEDICAL AND LEGAL, OF INSANE PATIENTS. By G. Fielding Blandford, M.D. Oxon. New York: William Wood & Co., 1886.

The present volume is one of the issues for the year 1886 of William Wood's Standard Library, and is, we presume, a reprint of the London book, or, in other words, is one of those appropriations of the property of other people which, being at present legal, are still

respectable, but which the passage of a proper International Copyright law will make a moral crime. We have read a great part of the book with much satisfaction. The English is good and clear (we wish as much could be said of the type), and the whole impress left upon the mind is that the work is the product of one who possesses good common sense, has not been driven mad by an excess of German speculative medicine, and has seen much of insanity. We have been especially interested in the chapter upon classification, which practically leads to the conclusion, which we ourselves reached some time ago, that there is at present no possible satisfactory classification of insanity. Perhaps we might confess that we have had an acute attack of the Germanic fever, but are now in that condition of exhaustion preceding convalescence which leaves the mind full of remorse and good determinations for the future, and that the present volume has been decidedly tonic in its action upon it.
